Instituto Tecnológico de Costa Rica

Escuela de Electromecánica

Informe Final de Práctica de Especialidad para optar por el grado de Licenciado en Ingeniería en Mantenimiento Industrial

Proyecto Administrativo:

Mantenimiento Preventivo aplicado a Aerogeneradores Neg Micon NM750.

Proyectos de Diseño:

Análisis de Vibraciones en Cajas Multiplicadoras y Generadores, aplicados a fallas en rodamientos y engranajes.

Programa de implementación de un Historiador de datos en los Aerogeneradores por medio de PLCs de comunicación.

Planta Eólica Aeroenergía S.A.

Realizado por Carlos Vargas González

Tejona, Tilarán. 2004

Profesor Asesor: Ing. Gustavo Jiménez

Asesor en la Empresa: Ing. José Ángel Prati

Nota a la versión impresa:

El informe completo con la totalidad de los anexos se muestra en el documento digital de Microsoft Word que lleva como nombre Informe Final de Práctica. Algunos anexos se omiten por motivo de espacio.

Dedicatoria

En la base de esta práctica está el señor José Ángel Prati.
El es quien merece la dedicatoria.
También el profesor Gustavo Jiménez por su paciencia
(a quien le deseo éxitos).
Sin embargo, también deben figurar en ella
aquellos que pasean conmigo por la vida:
Miguel, mis familiares,
mis compañeros de estudio, los héroes;
aquellos que entran y salen,
y aquellos que están por entrar.
A la promesa de las energías limpias.
A la promesa del FUTURO.

Glosario para términos provenientes del idioma Inglés

Enveloping: Traducido por SKF como Envolvente. Técnica matemática de análisis

SEE: Spectral Emitted Energy o Energía Espectral Emitida. Técnica de análisis.

HFD: High Frecuency Detection. Detección de Altas Frecuencias. Técnica de análisis.

FFT: Fast Fourier Transform. Transformada Rápida de Fourier. Función Matemática.

Trafo: Abreviatura de Transformador en inglés.

Tip: Punta móvil del aspa.

Slip Ring: Anillos deslizantes. Dispositivo de transmisión de señales eléctricas.

Nylon: Material de los conos en las aspas.

Coolant: Anticongelante. Líquido que mejora las propiedades del agua.

OPC: OLE for Process Control. Norma para dispositivos de control de procesos.

PLC: Programmable Logic Controller. Controlador Lógico Programable.

RCM: Reliability Centered Maintenance. Mantenimiento Centrado en la Confiabilidad.

TPM: Total Productive Maintenance. Mantenimiento Centrado en la Confiabilidad.

Buffer: Lugar de la memoria RAM.

Send: Función de enviar información.

Receive: Función de recibir información.

FMEA: Failure Mode and Effect Analysis. Análisis de Modos de Falla y Efectos.

Impeller: Impulsor.

Bearing: Rodamiento.

Service: Servicio de inspecciones de mantenimiento.

Sensar: Percibir un fenómeno y representarlo por medio de una señal.

1. Resumen

Este resumen presenta los tres innovadores proyectos realizados en la Planta Eólica Aeroenergía S.A. durante el primer semestre del año 2004.

El proyecto administrativo plantea el problema y una solución al complejo Mantenimiento Preventivo para este tipo particular de tecnología. Los rasgos principales del Mantenimiento Preventivo como la codificación, los manuales, las inspecciones y la planificación se conservan. No obstante, el documento se complementa con procedimientos o diagramas de flujo para control de alarmas, con diagramas de las máquinas y también con una gran recopilación de información digital básica para el mantenimiento ágil del parque, obtenida a lo largo de la investigación.

El proyecto de Análisis de Vibraciones en Cajas Multiplicadoras y Generadores, aplicados a fallas en rodamientos y engranajes representó un reto en la búsqueda de información y el análisis de los sistemas. El objetivo del Plan fue lograr un sistema de Análisis de Vibraciones completo y lo más simple posible para este tipo de máquina en particular. En él se realizan análisis y cálculos para estimar el comportamiento de las vibraciones en los sistemas de cajas planetarias y en los generadores de Aeroenergía S.A. A lo largo del estudio se hace uso de información producto de la persistencia y meses de indagación. El proyecto detalla desde la configuración de las mediciones y rutas para la toma de datos hasta las particularidades matemáticas. El resultado es una metodología única que contempla todas las etapas del Análisis de Vibraciones y plantea los próximos pasos a seguir en estas técnicas predictivas. Por otro lado, por su impacto directo en la operación, el mantenimiento y la gestión del equipo resulta fácil de justificar económicamente.

La gran ventaja del análisis de vibraciones en turbinas eólicas es que refleja el estado real de la máquina de manera bastante fidedigna y permite intervenciones en el momento mismo en que los datos se analizan sin esperar a que los activos se deterioren; tarea imposible de realizar por otros medios de diagnóstico.

Como tercer proyecto se presenta la primera de cuatro fases de desarrollo de un Historiador de datos de proceso en los Aerogeneradores por medio de PLCs de comunicación serial 485. En él se seleccionan sensores y dispositivos para ampliar el rango de acción de las alarmas existentes y lograr la comunicación y almacenamiento de sus datos de manera permanente.

De esta forma, los tres proyectos versan sobre aspectos esenciales de los sistemas eólicos y por ello implican un hito en el manejo del parque como totalidad. Con la conclusión de la práctica, se espera la continuidad de los proyectos por parte de la administración de Aeroenergía S.A. por el valor que encierran para la empresa.

2. Introducción

A continuación, se expone conceptos básicos para la compresión del presente documento.

2.1. Tendencias del Mantenimiento[1]

Por "Mantenimiento de Máquinas" debe entenderse el conjunto de acciones destinadas a conservar o llevar de nuevo el equipo a su funcionamiento óptimo, bajo ciertos estándares de operación y seguridad.

2.1.1 El Mantenimiento Correctivo

El primero de los paradigmas de Mantenimiento consiste en dejar que la máquina falle para intervenirla. El Mantenimiento Correctivo es y ha sido funcional cuando la producción no es un aspecto apremiante, cuando los costos ocasionados por dar otro tipo de mantenimiento a la máquina son más elevados que dejarla fallar o cuando no tiene sentido darle otro tipo de mantenimiento. Por ello, el Mantenimiento Correctivo ofrece como ventajas una inversión mínima y relativamente pocos gastos administrativos. No obstante, este paradigma acarrea gastos elevados por destrucción y deterioro de partes de la máquina, pérdidas que no se pueden enmendar en la producción y una gran cantidad de repuestos en bodega. Incluso, por la premura de reanudar el funcionamiento de la máquina, la máquina recibe muchas veces una solución temporal e indeseable para resolver su problema.

[1] Todo este apartado se basa en la información detallada en: "Compilación de Material sobre Análisis de Vibraciones de SKF" y "Folleto del curso de Administración del Mantenimiento I".

2.1.2 El Mantenimiento Preventivo

El Mantenimiento Preventivo nació por la necesidad de mejorar los resultados del paradigma de Mantenimiento Correctivo.

Con el Preventivo, las empresas decidieron no dejar que las máquinas fallaran y se propusieron minimizar los paros imprevistos y sus elevados costos. Dentro de las acciones por tomar en un Preventivo, están las de estudiar las máquinas, hacer inspecciones para verificar su condición, probar las máquinas, hacer ajustes y estudiar los momentos óptimos para el cambio de piezas que están prontas a fallar. Este paradigma mejoró considerablemente los resultados del anterior sistema pero también tenía implícitas ciertas desventajas. El Mantenimiento Preventivo se popularizó porque las máquinas fallaban menos, operaban en mejores condiciones y porque los operadores y técnicos utilizaban herramientas administrativas útiles para obtener experiencia y mejores resultados. Sin embargo, pronto se descubrió que en las rutinas de mantenimiento se cambiaba piezas que aún contaban con una vida útil considerable; que muchas catástrofes no eran evitables sólo con los criterios de Prevención; que los gastos por cambios innecesarios de piezas aumentaron y que las empresas estaban lejos de lograr que sus máquinas no fallaran. Estas necesidades no satisfechas darán cabida a los siguientes paradigmas de mantenimiento.

Cuando se habla de Mantenimiento Preventivo se habla de documentación. Entre los documentos usuales está la “Orden de Trabajo”, el “Historial de la máquina”, el “Reporte de fallas”, el “Cálculo de los valores de funcionamiento global”, los “Reportes de mano de obra directa”, la “Solicitud de compra de repuestos, materiales y herramientas”, el “Informe de movimiento de los repuestos en bodega” y la “Solicitud de salida de repuestos y materiales de la Bodega”.

Por eso, cuando se diseña un Programa de Mantenimiento Preventivo intervienen varios aspectos para lograr una propuesta específica para el sitio. En un Programa Preventivo se seleccionan las máquinas que entrarán dentro del mantenimiento, se valora su deterioro, se busca información técnica sobre la máquina, se codifica, se define los parámetros de funcionamiento global, se define los objetivos del Programa de Mantenimiento Preventivo y se hace divisiones de las máquinas en Partes y SubPartes. Además, se elabora un Manual de Mantenimiento Preventivo, se determina los repuestos necesarios para las inspecciones diseñadas, se calcula la disponibilidad de mano de obra para el mantenimiento y se procede a programar las inspecciones con fechas bajo el esquema de Gantt.

Eso explica porqué dentro del esquema básico del manual de mantenimiento se observa información sobre la codificación, la descripción, la frecuencia de las inspecciones, el tiempo de duración, el tipo de acción propuesta y la cantidad de técnicos necesarios para una inspección determinada.

Pese a sus desventajas, el Mantenimiento Preventivo es aún hoy una tendencia muy utilizada dados su facilidad de aplicación y relativo bajo costo.

2.1.3 El Mantenimiento Predictivo

A raíz de necesidades más imperantes en las empresas, celosas de la producción y las soluciones rápidas para los problemas, han surgido nuevos paradigmas de Mantenimiento, como el Mantenimiento Predictivo, el TPM, el RCM, el RCM 2, el Mantenimiento de Precisión y otros que resultan aplicables en empresas con una gran cantidad de máquinas, muchas actividades de mantenimiento y producción, un manejo de personal considerable, y un alto volumen de decisiones y coordinación.

El Mantenimiento Predictivo o “a Condición” pretende usar nuevas tecnologías para determinar la situación actual del equipo, monitorear su condición a lo largo del tiempo y lograr la detección de fallas e intervenciones en el momento justo en que deben realizarse por medio de la corrección de la raíz del problema. Lo usual dentro del Mantenimiento Predictivo es el Análisis de Vibraciones, las Termografías, el Análisis de aceite, los Ultrasonidos, los Rayos X y los Líquidos penetrantes, entre otros. Por medio de estas herramientas ingenieriles se pretende entender el funcionamiento de las máquinas y responder a preguntas básicas: el cómo, cuándo y porqué fallarán. Las desventajas que presentan las técnicas predictivas en general son: el alto costo inicial del equipo, lo indispensable de la capacitación del personal y, finalmente, el tiempo y la experiencia necesarias para que los resultados se tornen tangibles.

El Análisis de Vibraciones para rodamientos y engranajes fue inventado por la empresa SKF con el objetivo de obtener una herramienta de detección de problemas en máquinas rotativas. Los problemas detectables por medio del Análisis de Vibraciones son los de Soltura mecánica, Desbalance, Desalineación, Eje Torcido, Soltura de cojinetes, Fallas en la pista interior, en la pista exterior, en la canasta o en los elementos rodantes de los rodamientos, Fallas en los sistemas de engrane y Problemas de lubricación principalmente.

Para lograrlo, se vale de diversos tipos de instrumentos y métodos de análisis numéricos que toman las señales de vibración, las convierten en señales de Transformada Rápida de Fourier (FFT o Fast Fourier Transform) y usualmente despliegan resultados en forma de frecuencias y amplitudes de vibración de las que se vale el analizador de vibraciones para obtener un diagnóstico. La evolución de las fallas en las máquinas rotativas a partir del Análisis de Vibraciones inician de manera acústica e indetectable para el oído humano, luego continúa en forma de vibración y termina en forma de ruido hasta que la falla ocurre. Este comportamiento se muestra en la figura 2.1.3.1.

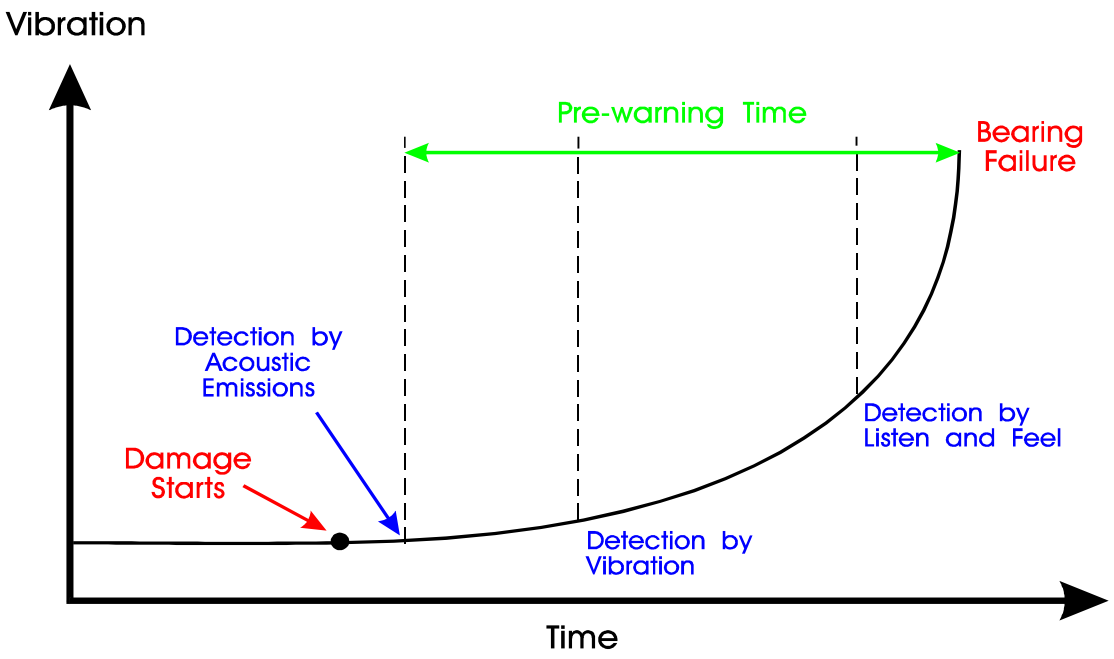

Figura 2.1.3.1. Evolución de la falla: Vibración vs Tiempo[2]

Para determinar la gravedad de las amplitudes para cada tipo de problema, el analizador debe recurrir a la Norma 2372 y a los estándares del fabricante. Si el personal de la planta no conoce los datos del fabricante debe al menos saber las velocidades de giro de los elementos. Debe conocer el tipo de rodamiento, el número de dientes de los engranajes y el número de aspas de las turbinas, para que por medio de ecuaciones y modelos matemáticos se pueda llegar a las frecuencias de falla.

Las ecuaciones simplificadas para encontrar las frecuencias de falla de los rodamientos por ejemplo, son los siguientes[3]:

a. Fi = BPFI (problemas en la pista Interior) = 0.6 (fr) (n)
b. Fe = BPFO (problemas en la pista exterior) = 0.4 (fr) (n)
c. Fb = BSF (Problemas en los roles) = (dm/(2d)) (fr) (1 – (d/dm)^2 (cos^2 β))

[2] Tomado de "Compilación de Material sobre Análisis de Vibraciones de SKF".
[3] Tomado de "Compilación de Material sobre Análisis de Vibraciones de SKF".

d. $Ft = FTF$ (Problemas en la canasta) $= (fr/2)\,(1 - (d / dm)\,(\cos \beta)$,

fr es la frecuencia de giro del rodamiento, n es el número de esferas por rodamiento, dm es el diámetro del rodamiento de centro a centro de las esferas, d es el diámetro de la pista interna y β es el ángulo de ataque del rodamiento.

Las frecuencias de falla de los engranes o de las turbinas en general (i.e. ventiladores) se obtienen de la multiplicación de la frecuencia de giro de los engranes por el número de dientes o aspas. En las cajas de transmisión es necesario saber la configuración de las ruedas, el número de dientes y la velocidad de cada rueda, así como el tipo de rodamiento que utilizan los ejes para poder determinar los datos básicos para el análisis.

Los parámetros más comunes por considerar son el Desplazamiento, Velocidad, Aceleración, la fase, el Enveloping, el SEE (Spectral Emitted Energy) y el HFD (High Frecuency Detection). Las señales de desplazamiento son utilizadas cuando las velocidades de rotación son bajas o cuando el movimiento de la máquina es indeseable. Para problemas en bajas frecuencias, como es el caso de la Soltura mecánica, el Desbalance, la Desalineación, el Eje Torcido y la Soltura de cojinetes, se utiliza la lectura de velocidad y la referencia de fase. Los problemas de alta frecuencia (como los problemas en engranajes, aspas y rodamientos), son detectados por medio de análisis de aceleración y para ello no es necesario tomar la referencia de fase.

La señal de Enveloping se obtiene de la manipulación de la señal de FFT. Una vez que la señal de la Transformada de Fourier se realiza, el colector de datos registra las señales de las armónicas de las frecuencias más significativas y las suma. Esto aumenta la amplitud original de la señal. De esta forma, la señal de Enveloping muestra picos que son producto de la señal principal original más las armónicas de esa misma señal. Esta técnica es utilizada por su efectividad en la detección de fallas en sus etapas más tempranas. Al ver el espectro, el analizador sabrá discernir fácilmente a cuáles frecuencias debe prestar atención y buscará a qué problema se refieren esas frecuencias.

A continuación se presenta una tabla de severidad para mediciones en Enveloping y diversas aplicaciones.

Tabla: 2.1.3.1. Tabla de severidad para valores de Enveloping y diversas aplicaciones[4]

SEVERIDAD		DIAMETRO DEL EJE (mm) / VELOCIDAD (rpm)		
F max 500 Hz	F max 1000 Hz	Ø 200 a 500 mm < 500 rpm	Ø 50 a 300 mm 500 a 1800 rpm	Ø 20 a 150 1800 a 3600 rpm
0,075	0,1	BUENO	BUENO	BUENO

[4] Tomado de “Compilación de Material sobre Análisis de Vibraciones de SKF”.

El SEE es una técnica especial para detección de problemas de lubricación o de inicio de problemas en cojinetes. El SEE registra muy altas frecuencias y tiene como resultado un número que engloba la energía emitida en un rango del espectro de FFT. Con estos datos se puede identificar una lubricación insuficiente, la contaminación del fluido o el comienzo de un defecto en el rodamiento. El HFD es un número global producto del análisis de las vibraciones en un rango de altas frecuencias y bajas amplitudes. El uso del HFD es especial para corroborar la tendencia de un rodamiento a fallar pero no indica nada acerca de las causas de la falla.

Los sensores más usados son los de aceleración, pues por medio de ellos el analizador de vibraciones puede integrar la señal y obtener las lecturas de velocidad; también puede obtener la señal de Enveloping, principalmente. Los acelerómetros funcionan por el efecto piezoeléctrico, muchos de ellos son aptos para alta temperatura y requieren de dispositivos electrónicos para producir su señal.

El análisis de los espectros implica no solo la identificación de frecuencias puntuales, sino también la interpretación de las frecuencias de los armónicos múltiplos de las frecuencias de falla, en bajas y altas frecuencias. Como se muestra en la Figura 2.1.3.2, el determinar que una falla está presente implica la existencia de armónicos de la frecuencia de la falla.

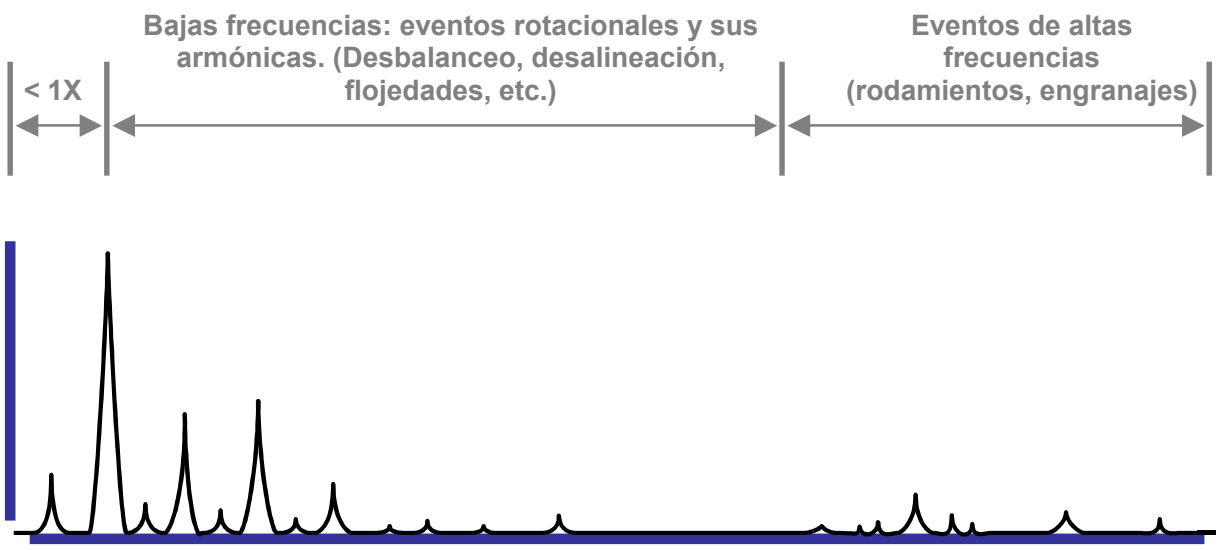

Figura 2.1.3.2 Análisis de armónicos en bajas y altas frecuencias[5]

Las fallas evolucionan por etapas. En la primera etapa no existen mayores amplitudes en la frecuencia de falla ni en sus armónicas. En la segunda etapa las armónicas de la frecuencia de falla aparecen. En una tercera etapa aparecen defectos en las frecuencias de falla. Y finalmente, aparecen bandas laterales en las armónicas y en las frecuencias de falla. Estas etapas pueden ser vistas en la figura Figura 2.1.3.3.

[5] Tomado de "Compilación de Material sobre Análisis de Vibraciones de SKF".

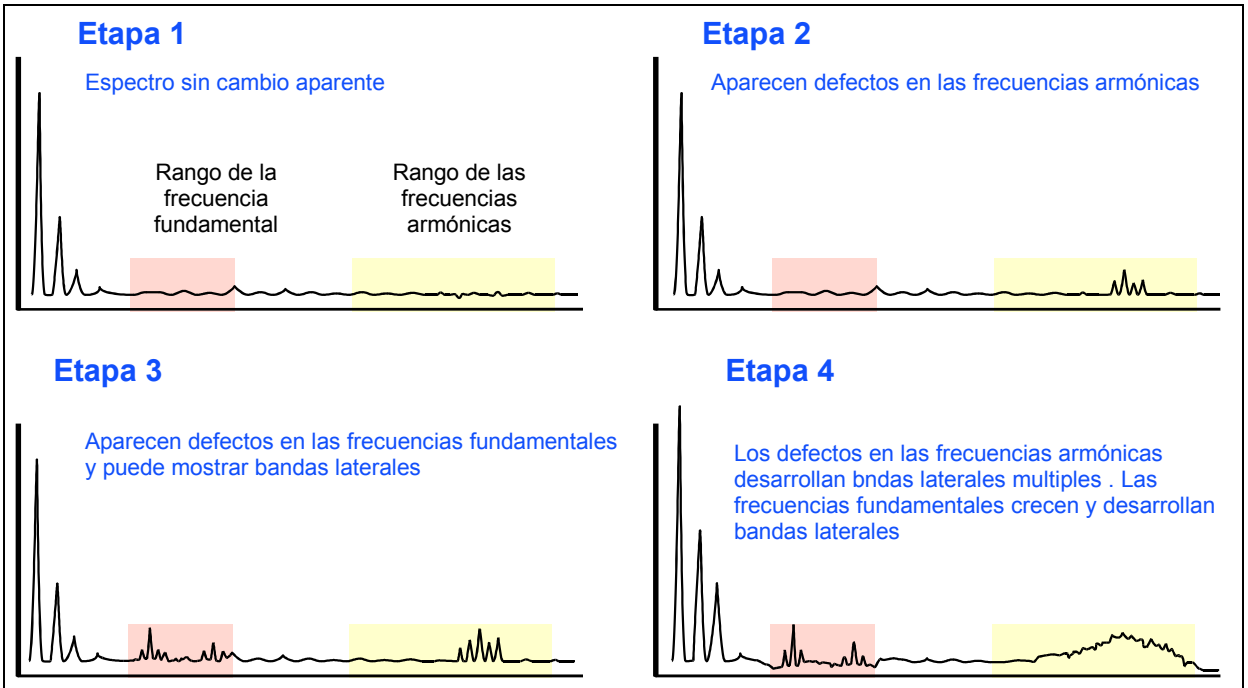

Figura 2.1.3.3 Etapas en la evolución de una falla[6]

Si se considera estos aspectos, además de contar con la experiencia y con las recomendaciones del fabricante, el personal de vibraciones puede iniciar su monitoreo.

Una de las formas más comunes de hacer monitoreo de vibraciones consiste en visualizar los registros de vibraciones de diferentes días desplegadas bajo una misma línea de coordenadas o en forma de cascada. De esta manera, el analizador de vibraciones percibe los cambios y el nacimiento de fallas en sus etapas tempranas tal y como se observa en la Figura 2.1.3.4.

[6] Tomado de "Compilación de Material sobre Análisis de Vibraciones de SKF".

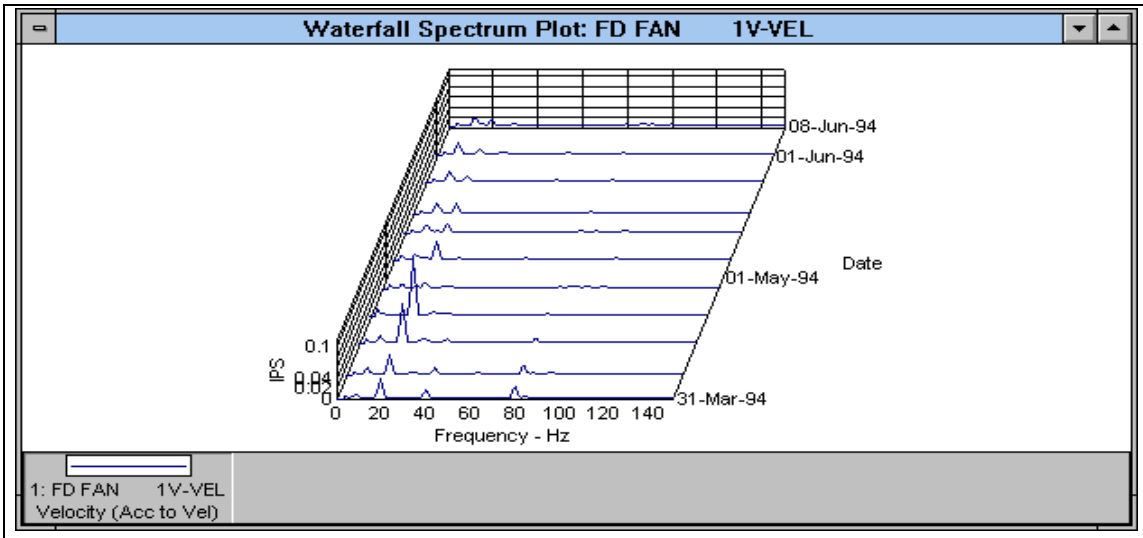

Figura 2.1.3.4 Cascada de espectros de vibraciones[7]

Una forma de reconocer la gravedad de la condición de un punto cualquiera en la máquina, sin saber la causa y el porqué, es el monitoreo de los Valores de Tendencia Global en Velocidad cuya normativa es la ISO 2372 de la Figura 2.1.3.6. [8].

[7] Tomado de "Compilación de Material sobre Análisis de Vibraciones de SKF".
[8] Un Hp equivale a 746 W.

Tabla 2.1.3.2 Tabla de severidad en los Valores Globales para velocidad de la Norma ISO 2374[9]

Vibration Severity Range Limits (Velocity) From ISO 2372		Vibration Severity Ranges for Machines Belonging to:			
In/Sec (PK)	MM/Sec (RMS)	Class I < 20 HP	Class II 20-100 HP	Class III >100 HP	Class IV >100 HP
0.015	0.28	A	A	A	A (Good)
0.025	0.45				
0.039	0.71	B			
0.062	1.12		B		
0.099	1.80	C		B	
0.154	2.80		C		B (Allowable)
0.248	4.50	D		C	
0.392	7.10		D		C (Tolerable)
0.617	11.2			D	
0.993	18.0				D (Not Permissable)
1.540	28.0				
2.480	45.0				
3.940	71.0				

A: Good
B: Allowable
C: Tolerable
D: Not Permissible

Suggested Classifications:

Class I: Small (up to 15kW) machines and subassemblies of larger machines.

Class II: Medium size (15kW to 75kW) machines without special foundations, or machines up to 300kW rigidly mounted on special foundations.

Class III: Large rotating machines rigidly mounted on foundations which are stiff in the direction of vibration measurement.

Class IV: Large rotating machines mounted on foundations which are flexible in the direction of vibration measurement.

[9] Tomado de “Compilación de Material sobre Análisis de Vibraciones de SKF”.

2.1.4 El Mantenimiento de Precisión

Según la tendencia, se espera que el siguiente paradigma dentro de las filosofías del mantenimiento sea el Mantenimiento de Precisión. Basado en el Mantenimiento Correctivo, el Mantenimiento Preventivo y el Mantenimiento Predictivo, el Mantenimiento de Precisión trataría de que cuando se realice un trabajo de reparación, la máquina quede en las mejores condiciones posibles. Ello implica una ardua tarea de entrenamiento en herramientas y refacciones de calidad, calibración, balanceo y alineación de máquinas. Por los altos costos y la complejidad de este mantenimiento se espera que sea exitoso en áreas donde la expectativa de fallos sea mínima y donde el valor de la maquinaria sea elevado lo suficiente como para deteriorar el equipo con un mal mantenimiento.

2.1.5 El Mantenimiento Programado

El Mantenimiento Programado es un tipo de mantenimiento circunstancial que resuelve problemas de manera programada fuera del Mantenimiento Preventivo. Estas tareas surgen de la toma de conciencia sobre problemas, nace de incidentes recientes, de la realización rutinaria del mantenimiento preventivo, de la necesidad de modificar parámetros en las máquinas, de la avería y cambio de una máquina o de alguna actividad inconclusa en las rutinas de mantenimiento preventivo. Dentro de un Plan de Mantenimiento Preventivo debe dejarse el tiempo suficiente para poder realizar Mantenimiento Programado. Los Aerogeneradores implican una gran cantidad de Mantenimiento Programado. Así, en un mismo parque un problema que se encuentra en una máquina tiende a hacerse presente inmediatamente en el resto del parque y por ello deben programarse acciones correctivas de forma pronta.

2.1.6. El TPM, el RCM y el RCM 2

El TPM, el RCM y RCM 2 son técnicas que implementan las filosofías fundamentales del Mantenimiento (Mantenimiento Correctivo, Preventivo, Predictivo y de Precisión) basadas principalmente en la toma de decisiones y en el personal.

El objetivo del TPM (Total Productive Maintenance) o Mantenimiento Productivo Total es centrarse en aquellas funciones que permitan preservar el funcionamiento de los equipos bajo estándares de operación deseables. Por ello se apuesta a equipos de trabajo altamente capacitado (Empowerment) que puedan tomar decisiones por sí mismos (Mantenimiento Autónomo) mediante un esquema de organización horizontal donde la solución de los problemas sea definida en una acción conjunta. El TPM busca, a su vez, la simplificación de las metas, el entendimiento de las máquinas, el trabajo conjunto con el área de producción, la implementación de procedimientos, el aprovechamiento de la sinergia y la motivación del personal, y el mejoramiento continuo. Por ello se dice que el TPM impacta principalmente en la cultura de la empresa. El éxito del TPM se ha mostrado en empresas donde la coordinación entre Producción y Mantenimiento es fuerte así como donde la producción y el manejo del personal puede resultar complejo.

El RCM y el RCM2 (Reliability Centered Maintenance) o Mantenimientos Centrados en la Confiabilidad Operacional son tendencias de gestión que pretenden la optimización de la confiabilidad operacional de las máquinas seleccionadas por parte del equipo de trabajo mediante la meditación y la programación de las medidas más adecuadas. Valora la criticidad y prioridad de cada activo en relación con cómo afecta la producción y cómo atenta contra la seguridad y el ambiente. Ambos utilizan los FMEAs (Failure Mode and Effect Analysis) o Análisis de Modos y Efectos de Falla para deducir las mejores acciones por tomar. El Mantenimiento Centrado en la Confiabilidad se ha mostrado efectivo en procesos complejos en los que la solución de las fallas no parece obvia.

2.2 Los Controladores Lógicos Programables (PLC)

2.2.1 Los PLCs

Los PLCs o Controladores Lógicos Programables nacieron con la idea de reemplazar los antiguos sistemas de control basados en contactores, “relays” y demás dispositivos de naturaleza mecánica y eléctrica. No obstante, los PLC han ido más allá de ser controladores de entradas y salidas. También realizan operaciones matemáticas y comunican información por medio de redes bajo diversos protocolos de comunicación, entre otras funciones.

Los PLCs son usualmente programados por medio de Lenguaje de Escalera o Ladder. Estos lenguajes permiten obtener información rápidamente de manera visual mediante la utilización de funciones lógicas estandarizadas.

Es importante resaltar que un proyecto de automatización o comunicación por medio de PLCs difícilmente puede iniciarse sin haber elegido un controlador, pues cada marca ofrece diferentes formas de programar y diferentes funciones.

2.2.2 Conceptos fundamentales de la comunicación electrónica

Algunos de los conceptos principales de la comunicación son los siguientes:[10]

a) Bit: Mínima unidad de medida de información con dos estados posibles.

b) Byte: Secuencia de 8 bits

c) Word o Palabra: Línea de bits.

d) Protocolo de comunicación: El protocolo de comunicación es el conjunto de reglas que definen el formato y la transmisión de datos entre dispositivos electrónicos.

e) Protocolo de Texto ASCII: Es el protocolo más sencillo y lento. La comunicación es basada en texto. Requiere de 7 bits y está contenido en campos de 8 bits.

f) Protocolo Modbus: Protocolo de Comunicación especial para comunicación de programas de computadoras y aplicaciones de automatización.

[10] Todas estas definiciones, con la excepción de las de la comunicación Serial, fueron basadas en las definiciones de la página: hyperdictionary.com

g) Puertos serial: RS-485, RS-232, RS-422: La comunicación RS-232 utiliza señales representadas por voltajes con referencia a una señal de tierra. Es utilizada para conexiones punto a punto (un dispositivo, una conexión). La comunicación RS-485 y RS-422 es parecida por su par trenzado de cables con voltajes alternados de 0 a 5 Volt. No obstante, el RS-422 usa dos pares de cables por lo que puede transmitir y recibir de punto a punto. El RS-485 funciona para comunicación multipunto, con muchos dispositivos conectados en un mismo cable bajo direccionamientos y sistemas de Esclavo y Maestro[11].

h) Baud Rate: unidad de medición de la capacidad de envío de información de un canal. Un baudio equivale a un estado por segundo.

i) Bit de paridad: es un bit agregado a una transmisión de datos binaria con tal de identificar por medio de un 1 o un 0 si la transmisión de datos es un número “even” o “odd” (par o impar).

j) Bit de término (Stop Bit): Una vez que todos los bit de una línea se han transmitido, se posiciona un 1 como bit de término seguido del bit de paridad. Este bit denota el fin de una unidad de información.

k) Buffer: Lugar temporal en la memoria RAM donde los datos esperan para ser enviados a otras locaciones de memoria o a otros dispositivos.

[11] Tomado de la dirección: http://www.hw.cz/english/docs/rs485/rs485.html

2.2.3. Sensores Analógicos y Digitales

Los sensores digitales son utilizados en casos donde existen dos estados posibles, como encendido - apagado, o presente - no presente. Ese es el caso de los sensores de RPM, los sensores de proximidad, los interruptores y demás. Lo usual es encontrar que las salidas de estos sensores son de 24 Volt.

Los sensores analógicos son utilizados para sensar parámetros que crecen o decrecen progresivamente y poseen una densidad de datos significativa. Usualmente los sensores analógicos reflejan por medio de rangos de corriente de 4 a 20 mA, estados que van desde un nivel inferior hasta un nivel superior. Las típicas mediciones analógicas son de temperatura, viento, flujo, etc.

2.2.4. PLC Mitsubishi FX $_{1N}$- 14MR

La particularidad de la PLC Mitsubishi FX $_{1N}$ -14MR reside en su tarjeta de RS-485. Esta tarjeta la habilita para comunicarse vía puerto serial con otros dispositivos que también estén diseñados para comunicarse por RS-485. Además contiene una serie de funciones para manipular los datos.

Para diseñar y monitorear los programas en el PLC Mitsubishi FX, se utiliza el programa Melsoft GX Developer. Este software permite acceder a las funciones, monitorear las variables, diseñar las decisiones lógicas y comunicar el PLC.

2.2.5. Funciones lógicas y elementos básicos del lenguaje de Escalera del PLC Mitsubishi FX $_{1N}$- 14MR

En el lenguaje visual de escalera el elemento principal es el contactor. El contactor se representa por dos líneas paralelas y verticales, con la letra X y un número que lo diferencia de otros contactores. Los contactores usan el mismo concepto que los interruptores: cuando son activados se cierran (eso es cierto cuando los contactores son normalmente abiertos) con lo que permiten el paso de energía entre las dos líneas de los lados del diagrama. Con las señales de entrada, los PLC toman decisiones, realizan operaciones o almacenan y transfieren información.

El otro elemento básico de los diagramas son las salidas, que son encerradas entre paréntesis y denotadas con una Y más un número que la identifica. Las salidas actúan como interruptores de elementos en el proceso real. Las salidas activan las máquinas o los dispositivos a partir de las señales y estímulos en las entradas, o a partir de decisiones en el programa del PLC.

Algunas de las funciones principales son: RST (Reset), C0 (Contador), T250 (Timer), Mov (Mover datos), Div (División de datos) y End (Fin de la programación). La función Reset sirve para volver la cuenta a cero en algunas funciones como los temporizadores, los contadores, y otros. La función del Contador es sumar la cantidad de veces que se pulsa un contactor en la entrada designada para ello. Cuando la cuenta llega a un valor determinado, se activa un contactor del contador.

Los temporizadores se parecen a los cronómetros en su función. Cuando son energizados en la entrada de disparo, los temporizadores inician la cuenta del tiempo hasta que algo la detiene.

El comando Move es utilizado para mover datos de un lugar de memoria a otro.

Los lugares de memoria se designan con la letra D más un número diferenciador. La función del comando División es la de efectuar una división de dos valores en memoria y almacenar el resultado en otro Buffer. Finalmente, la función End fuerza al PLC a reconocer la conclusión del programa. Al declarar End al final del diagrama de escalera el PLC funciona de forma más rápida que si no tuviera esa función.

2.3. Explicación básica del funcionamiento de los Aerogeneradores Neg Micon NM750.

Las turbinas eólicas Neg Micon NM750 utilizadas en Aeroenergía son sistemas con tres aspas en el rotor, sistema de freno en las puntas de las aspas (Tips), Caja multiplicadora de velocidad y un generador asincrónico. Además de esos componentes tiene sistemas de orientación con el viento para el mayor aprovechamiento de la energía, tiene un sistema de freno de disco en el rotor y cuenta con un complejo sistema de monitoreo y control de variables.

La función de la caja multiplicadora de velocidad está en el generador. El generador está conectado a la malla del ICE y por ello el campo en el estator gira a 1812 rpm aproximadamente para 4 polos. Ahora bien, las aspas por sí solas no pueden girar a 1812rpm con la simple acción del viento. Por ello debe diseñarse el sistema para que gire a una velocidad mucho menor y que esta sea incrementada en la caja multiplicadora de velocidad.

La parte superior de la turbina es llamada góndola. La góndola se sitúa a 40 metros sobre la tierra. Dentro de los aspectos de seguridad debe tomarse en cuenta que trabajar a esas alturas, con un alto nivel de vibraciones, una gran cantidad de dispositivos en movimiento, suciedad y calor, puede resultar peligroso y por ello las tareas de mantenimiento se dificultan.

2.4. Explicación básica del funcionamiento del Programa iHistorian y el OPC[12].

El programa "iHistorian" es un software innovador de almacenamiento de datos especial para procesos industriales. El iHistorian está en capacidad de colectar datos cada 1/1000 segundos. Los datos pueden ser manipulados por sistemas comunes de bases de datos como SQL. Esto proporciona una mayor practicidad a la herramienta. Con el iHistorian los datos entran provenientes del proceso hacia el servidor OPC y de allí a módulos de visualización donde ayudan al personal a tomar decisiones administrativas. Es compatible con las principales marcas de sistemas de control del mercado porque opera bajo el concepto de OPC.

OPC significa *OLE for Process Control*. Las siglas OLE representan Object Linking and Embedding (Vínculo y fijación de objetos), que es un sistema distribuido de objetos creado por Microsoft. La OPC es entonces una especificación hecha para simplificar las tareas de comunicación en la industria, a partir de sistemas de direccionamiento y compatibilidad con productos Microsoft. Así, el usuario o cliente puede conectarse a un proceso moderado por un PLC y observar los datos que le envía el servidor. Ese servidor opera como un programa en la computadora que aplica la especificación de OPC.

Además, General Electric ha concebido el programa "info Agent" con tal de poder transferir la información a diferentes computadoras y proporcionar conectividad con redes.

[12] Basado en la información de la página web: www.softwaretoolbox.com

2.5. Explicación básica del funcionamiento del programa Prism4 de SKF y el Colector de datos CMVA-55 Microlog para análisis de Vibraciones

El programa Prism4 es utilizado por diferentes tipos de tecnologías en análisis de vibraciones de la empresa SKF. Prism4 permite diseñar las rutas de análisis de vibraciones y determinar los parámetros de cada punto. Con la ruta de mediciones lista, el personal encargado puede proceder a descargar la ruta en la máquina colectora de datos CMVA-55 Microlog y con ello tomar las señales de las máquinas.

Con los datos de las máquinas en el Microlog, el personal puede cargar los datos en la computadora y visualizar las tendencias de vibración, los espectros y los valores globales, entre otros. En ese sentido, el programa Prism4 se convierte en una herramienta de base de datos.

3. Reseña sobre la Planta Eólica de Aeroenergía S.A.

3.1 Historia de Aeroenergía S.A.

La empresa Aeroenergía S.A. se construyó en 1994 con el propósito de co-generar energía eólica en conjunto con el ICE con el amparo de la Ley No. 7200. Esta ley ha regido la generación autónoma y paralela de energía en Costa Rica. El contrato de compra – venta con el Instituto Costarricense de Electricidad se firmó el 14 de abril de 1997.

3.2 Organigrama de la empresa

Aeroenergía es una empresa pequeña con una estructura simple como se muestra en el Organigrama.

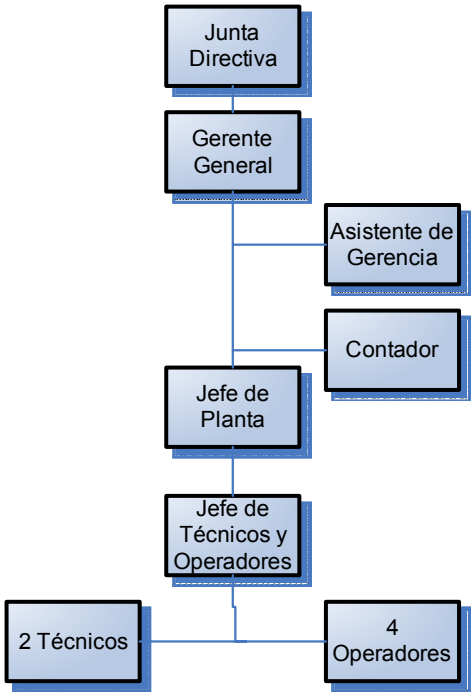

Figura 3.2.1. Organigrama de Aeroenergía S.A.

3.3 Tecnología utilizada

El diseño original de las turbinas corresponde a la M1800 NM750 de la empresa Neg Micon, con paso fijo, dos velocidades y generadores asíncronos de 1812 y 1210 rpm (de 750 y 250 kW). La máquina viene equipada con sistema de sensores y un controlador WP3000 que coordina las acciones de la turbina y dispara alarmas en caso de fallo.

Como se puede observar en los manuales de la máquina que se presentan en el Anexo 38, la máquina está equipada con un rotor, tres aspas, un eje, una caja multiplicadora, acoples y un generador. Además contempla motores y frenos de orientación lateral para hacer frente al viento en cualquier momento, y un complejo sistema de control.

4. Mantenimiento Preventivo aplicado a Aerogeneradores Neg Micon M1800, 750kW

4.1 Definición del problema

Conocedores de la diferencia entre el estilo del Mantenimiento Industrial común y el Mantenimiento de Aerogeneradores, Aeroenergía S.A. aceptó el proyecto de Mantenimiento Preventivo como forma de probar con nuevas herramientas para hacer frente a las tareas diarias en la planta.

El campo de la energía eólica está aún en su etapa de desarrollo. Por eso, cada día se encuentra mejores diseños de aerogeneradores y formas de dar mantenimiento al equipo. El mantenimiento de los aerogeneradores difiere en gran medida del Mantenimiento Industrial por varios motivos. La mayoría de los componentes de la turbina se encuentra en sitios de difícil acceso, en condiciones incómodas y peligrosas. Es por ello que la estancia en el sitio debe ser la mínima y eso dificulta el acercamiento con la máquina para aprender de ella. Además limita poder asumir las tareas de mantenimiento debido a la falta del equipo adecuado para efectuar múltiples tareas.

Bajo regímenes de viento fuertes, como es el caso usual de ciertos periodos en la zona de Tilarán, Guanacaste, el acceso a la máquina no es posible e incluso las máquinas deben detenerse ante una operación insegura con vientos por encima de los 25 m/s. En esas condiciones, la máquina no volverá a iniciar su funcionamiento sino hasta que el viento se mantenga a menos de 18 m/s durante un mínimo de diez minutos.

Dadas algunas cuestiones de seguridad, lo impredecible del viento, los elevados costos de tener la máquina detenida con vientos adecuados para la producción eléctrica y lo pequeño del parque, el mantenimiento necesita de una comunicación rápida que se despliegue a todos los niveles de la empresa para la toma de una decisión determinada. La flexibilidad y eficiencia necesarias en esta aplicación hace del sistema de Órdenes de trabajo un sistema inaplicable. En cambio, la comunicación, análisis y autorización de las intervenciones se realiza por vía telefónica, vía radio-transmisor o por Internet y estos medios resultan más adecuados a un parque de 9 turbinas donde las intervenciones son poco usuales y deben ser decididas con rapidez.

Frente a dichas particularidades de los parques eólicos, el fabricante Neg Micon A/S desarrolló un tipo de mantenimiento basado en Alarmas y por inspecciones que se realizan cada 6 meses y cada 2 años, llamados Service B y C respectivamente.

El Service A corresponde a una rigurosa inspección al inicio de las operaciones del parque. Este sistema de Service tiene una naturaleza altamente preventiva y programada con aplicaciones eventuales de técnicas predictivas como el análisis de aceite y el análisis de vibraciones. Usualmente, estas inspecciones se realizan entre septiembre y octubre, o en abril, cuando los vientos son escasos y la pérdida de energía derivadas de detener las turbinas es menor.

Algunos de los documentos del Mantenimiento Preventivo que Aeroenergía mantiene al día son: el Historial de la máquina (bitácora ubicada en el Panel de Control de cada turbina), el Reporte de fallas, los Valores de funcionamiento global (Curva de potencia versus velocidad de viento), los Reportes de mano de obra directa (Informe semanal de labores), y la Solicitud de compra de repuestos, materiales y herramientas.

De los documentos usuales, el Informe de movimiento de los repuestos en bodega, o la Solicitud de salida de repuestos y materiales de la Bodega no son utilizados porque la bodega es relativamente pequeña. La experiencia de Aeroenergía muestra que no es conveniente tener muchos repuestos en bodega por lo caro de las partes, porque algunos de ellos pueden ser obtenidos en la Planta eólica Movasa y por el deterioro normal. En caso de visualizarse la necesidad de repuestos se hace una requisición a Neg Micon Dinamarca y en cuestión de días los repuestos llegan a la Planta.

Gran parte de la información de la máquina es considerada por Neg Micon A/S como confidencial. Eso obstruye la posibilidad de dar un mantenimiento certero por parte de los dueños de las máquinas.

En ese sentido, la tarea fundamental de esta práctica de especialidad es estudiar la máquina, los múltiples cambios que ha sufrido, colectar información de sus partes, recopilar parte de la experiencia de los encargados del mantenimiento de Aeroenergía y traducirla en el diseño y programación un Plan de Mantenimiento con su respectivo Manual de Mantenimiento, sus diagramas detallados, imágenes y sus inspecciones.

4.2 Fuentes de información

El presente trabajo de Mantenimiento Preventivo se ha basado en la experiencia que ha dejado el quehacer de las inspecciones o Service en manos de terceros a lo largo de los años. De esta forma, ha sido difícil determinar la efectividad de las acciones que se recomiendan en las presentes inspecciones, principalmente en aquellos casos nuevos que nunca han sido probados en estas máquinas.

4.3 Codificación del Parque

4.3.1 Codificación del Parque

Toda codificación en la Planta Aeroenergía comienza con las letras AE. Este inicio de código es necesario para evitar problemas en una eventual ampliación del uso de este documento y su posible utilización conjunta con la Planta de Energía Eólica Movasa.

Las componentes ingenieriles principales del parque se dividen en este documento en Turbinas, Subestación, Transformadores de las turbinas, Transformador del edificio y Torres de Meteorología. Por ello, cada uno de estos componentes tiene su propio código. Las Turbinas se denotan con la letra T más el consecutivo del número con el cual están ordenados en el Parque. Ejemplo: Turbina 1: AE-T01.

La Subestación está codificada con las letras SE. Ejemplo: Subestación: AE-SE.

Los transformadores de las turbinas se denotan con el código de la turbina a la que pertenecen más la letra T. Ejemplo: Transformador de T1: AE-T01-T.

El Transformador del Edificio se denota con TE. Ejemplo: Transformador del Edificio: AE-TE.

Las Torres Meteorológicas se denotan con TM más un consecutivo. Ejemplo: Torre Meteorológica 1: TM-1. La lista completa de la codificación se muestra en el Anexo 1.

4.3.2. Codificación de los bloques de mantenimiento

La codificación de las partes de la turbina se ha unido con la codificación de otros elementos que no están en la turbina (como por ejemplo, la subestación). Esto tiene el fin de usar esta codificación en los Manuales de Mantenimiento y en las inspecciones.

Las diferentes partes se han designado con números y no con letras porque muchas veces es difícil encerrar en abreviaturas los conceptos que engloba un bloque de mantenimiento.

En el presente trabajo se han conformado bloques de máquinas que desde el punto de vista del mantenimiento están muy relacionadas. Ese caso se presenta con el bloque de la Estación Hidráulica, el Aspa y el Tip, en la cual la interrelación es muy significativa, pese a que los sistemas son diferentes.

La codificación puede observarse en el Anexo 2.

4.4 Diagramas de la máquina

Al inicio de la práctica, Aeroenergía poseía esquemas básicos facilitados por Neg Micon sobre máquinas similares a la M1800 (NM 750). Sin embargo, a lo largo de los años a las máquinas originales les han cambiado el generador, la caja, los sistemas de enfriamiento y algunos otros sistemas. De esta forma, los diagramas originales no correspondían más a las máquinas actuales. Por este motivo los diagramas fueron re-dibujados en Autocad con la idea de poder rotular sus componentes y facilitar el entendimiento del Programa de Mantenimiento.

Los esquemas se muestran en el Anexo 3

4.5 Diseño de la documentación

Como se mencionó en la introducción, en Aeroenergía se llevan una serie de documentos que cumplen las funciones de la documentación básica del Mantenimiento. La explicación de los documentos es la siguiente:

4.5.1. Solicitud o Orden de trabajo

Como se indicó en la sección Definición del Problema, en Aeroenergía no se utiliza la Orden de trabajo principalmente porque los problemas de las máquinas deben ser comunicados rápidamente. En cuestión de minutos, todos en la empresa deben conocer el problema para poder encargarse de él o proponer una solución.

4.5.2. Historial de las Máquinas

Neg Micon utiliza una bitácora en el Panel de Control al pie de la Turbina. En esa bitácora se explican las labores de los Service y de otras intervenciones. Esa bitácora no se pasa a una versión electrónica, sino que se deja en el papel. Sin embargo, la única información que se lleva en la bitácora de la turbina es el detalle del trabajo, la producción acumulada, la fecha, la hora y el responsable de las labores.

Además de que el técnico apunte los acontecimientos en la bitácora de la Turbina, el operador del Parque anota en la bitácora de operaciones las labores de mantenimiento que ocurren en las máquinas. En el futuro, las hojas de Inspecciones darán información sobre las intervenciones.

4.5.3. Documento de Datos Técnicos

Parte de los datos técnicos de la Máquina se han obtenido del Manual de Operación de Micon y de un archivo llamado: datos_tech_750.pdf. Antes de esta práctica ningún manual o documento contenía la información unificada ni completa, de ahí parte de la misión del presente documento.

Otros datos han sido tomados directamente de las máquinas y su información buscada en Internet o solicitada al Fabricante. Pese a que la información es limitada, actualmente se cuenta con una buena cantidad de datos. Esa información se encuentra vinculada en la tabla del Anexo 38.

4.5.4. Reporte de fallas

El documento de Control de Alarmas es el que sustituye al tradicional Reporte de Fallas. Además de reportar fallas, el Control de Alarmas también indica los paros manuales de la máquina que ocurren cuando se realizan los Service. El reporte completo despliega información del tipo de Alarma por la que ha sido detenida, el número de turbina, la fecha en la que ocurrió la alarma, el número de error al que corresponde, la descripción del error, las condiciones de viento, producción, tiempo total de operación desde que inició la máquina, la persona informada de la alarma, el operador que se hizo cargo de la alarma, el detalle del problema, la hora en la que entró a funcionar de nuevo la turbina, el régimen de viento en el cual entró y el tiempo total durante el que estuvo detenida por la falla.

Este documento se lleva en versión electrónica e incluye la disponibilidad de las máquinas durante determinado periodo de tiempo (mes).

El documento se puede observar en el Anexo 8

4.5.5. Valores de Funcionamiento Global

En los Generadores Eólicos el patrón más significativo es la Curva de potencia versus velocidad de viento. Este dato es registrado por el Medidor de Calidad de Energía Mutilin de la General Electric. Los datos se guardan con un formato electrónico propio del programa. Así, los operadores deben guardar la curva de potencia tres veces al día.

4.5.6. Reportes de Mano de Obra Directa

Los encargados del mantenimiento llevan Informes semanales de labores. Estos informes se llevan a mano y puede observarse en el Anexo 9

4.5.7. Solicitud de compra de repuestos, materiales y herramientas.

La solicitud de salida de repuestos y materiales de la bodega no es utilizada porque la bodega es relativamente pequeña y las labores no son tan frecuentes como en aplicaciones industriales o de mayor escala. Las solicitudes de compras son planteadas oralmente al Jefe de Planta y al personal. Para ello, no se llena ninguna documentación. Cuando existe una compra o pago de alguna labor, se llena un formato en una hoja de Excel con el detalle de lo ocurrido.

Esa hoja de Excel se observa en el Anexo 10.

4.6 Manuales de Mantenimiento

Los Manuales de Mantenimiento contienen información sobre las subdivisiones de cada parte de la máquina, aclara la función de la parte, la codifica, estima una acción de mantenimiento adecuada para el programa, le asigna una periodicidad, un número determinado de técnicos, y estima un tiempo de realización de la tarea. Este manual es una guía básica para la reflexión sobre el diseño de las inspecciones. Los manuales se muestran en el Anexo 4. Los datos técnicos y los enlaces a manuales se observan en el Anexo 38. Los detalles acerca de la ubicación de cada parte se pueden observar en las fotos del Anexo 11 o en los esquemas del Anexo 3.

En los manuales, no se utiliza codificación para aludir al tipo de inspecciones, pues puede provocar confusiones.

4.7 Inspecciones

Las inspecciones están basadas en gran medida en el sistema de Neg Micon de Service tipo B y C; y del Mantenimiento Programado. Las inspecciones del presente documento fueron confeccionadas con la experiencia del personal de Aeroenergía, las recomendaciones del fabricante y la meditación sobre las tareas más acertadas de mantenimiento. Para aquellas tareas que no habían sido contempladas en los Service, se diseñó un tipo de inspección llamado Ex (Extras).

Las inspecciones indican la parte a la que le dan mantenimiento, el número de inspección e información sobre el resultado de la inspección con un espacio para hacer anotaciones. Además existe una casilla para llenar el tiempo real de finalización de la labor de manera que se pueda estimar mejor el tiempo de las labores futuras. En el momento de realizar las inspecciones se debe cambiar el código de la inspección, e imprimir. Antes de realizar la inspección debe llenarse la fecha en la que se realiza la inspección.

Las inspecciones pueden verse en el Anexo 5

4.8 Programación de actividades de mantenimiento propuestas

Como se mencionó en la Introducción, las actividades de mantenimiento se realizan en época de poco viento. Usualmente eso ocurre entre setiembre y octubre y de manera menos evidente en otros meses, para el caso de Tilarán. No obstante, si en determinado año el viento es bueno para la generación, la administración no permitirá que turbina se detenga y el mantenimiento no podrá realizarse. Por ello se dice que la Programación es una propuesta cuyo cumplimiento no depende del personal de la planta sino de las condiciones de operación en el momento.

El Gantt que se observa en el Anexo 6

4.9 Procedimientos frente a Alarmas

Las turbinas de Neg Micon M1800 (NM750) cuentan son un sofisticado sistema de alarmas que muestra el momento en que alguna anomalía se presenta. Parte de este trabajo de Mantenimiento Preventivo contempla el diseño de diagramas de flujo con instrucciones sobre cómo hacer frente a una alarma. Por ello, se han confeccionado diagramas de Flujo en el programa Microsoft Visio. Por cuestiones de tiempo y practicidad, las alarmas con diagramas de flujo son un porcentaje pequeño del total de alarmas del sistema. Sin embargo, fueron escogidas aquellas más frecuentes e importantes.

Los diagramas pueden observarse en el Anexo 7.

4.10 Aspectos de Seguridad o Precaución

Las tablas de inspecciones llevan notas de seguridad o precaución junto al número de la inspección. Los aspectos de precaución son descritos a continuación:

P1: Máquina en Service. Generador desconectado. Freno asegurado. Mínimo dos personas en la inspección. Cortar la comunicación del Panel con el Parque.

P2: Si para revisar los dispositivos es necesario intervenir el Panel, entonces se debe apagar la turbina. Poner la máquina en Service. Desconectar la alimentación. Desconectar la comunicación. Mínimo dos personas en la inspección. Freno asegurado.

P3: Cuidado con los elementos rotativos. Cuidado con el sensor esférico de vibración.

P4: Igual que P1. Además, desconectar la alimentación del dispositivo intervenido.

P5: Igual que P1. Además, anclar el freno para que las aspas queden en Y. Linga de seguridad atada al Rodamiento Principal. Casco.

P6: Igual que P5. Además, apoyar apropiadamente las plataformas de Sky Damper a la torre para trabajar en las aspas.

P7: Arnés y casco puesto. Alertar al personal. Cuidado en el manejo de herramientas y accesorios.

P8: Desconectar las turbinas. Aterrizar la subestación. Interrumpir los alimentadores.

P9: Cuidado con aislar los polos de la batería.

P10: Cuidado. Posibilidad de descargas eléctricas.

4.11 Análisis costo beneficio del Proyecto Administrativo de la Práctica de Especialidad

Con base en el contrato logrado entre el ICE y Aeroenergía S.A. se puede deducir un monto promedio de producción por turbina por hora de $45. El tiempo de la práctica fue de 5 meses. El costo administrativo que representa el practicante es de $541 (con un salario de $325 al mes). Un análisis rápido que no tome en cuenta el valor del dinero en el tiempo, indica que Aeroenergía vería paga su inversión según el siguiente cálculo

$$0 = \$45 \times h - \frac{5}{3} \times \$325; \qquad h = \frac{5 \times \$325}{3 \times \$45} = 12 \text{ horas}$$

cuando se logre 12 horas menos de paro en una turbina bajo el nuevo esquema. Eso corresponde a disminuir los tiempos de paro en un 7,6%, si se toma en cuenta que en el mes de marzo del 2004, las turbinas permanecieron detenidas 157,5 horas. Eso es fácilmente asequible pues con la información y herramientas del Programa de Mantenimiento Preventivo las decisiones se tomarán más rápido y las máquinas pasarán menos tiempo detenidas.

Otros beneficios no cuantificados del programa son: los Sistemas de inspecciones, los Procedimientos frente a alarmas y la Programación de las actividades de Mantenimiento. Por ello, el proyecto en realidad se paga en menos de las 12 horas indicadas.

4.12 Recomendaciones

Para lograr un nivel óptimo en el funcionamiento del mantenimiento y en vista del nivel de operaciones que la empresa Aeroenergía tendría que asumir en caso de una expansión, la empresa debería realizar actividades para fortalecer la visión de la toma de decisiones en conjunto y del trabajo en equipo.

Además, por la planificación y la complejidad de las labores de mantenimiento en estas condiciones, el personal debería capacitarse en técnicas de montaje, alineación y cambio de piezas para poder asumir cada vez más funciones en las máquinas. El personal debería adoptar la filosofía del Kaisen o del Mejoramiento Continuo de los Planes de Mantenimiento Preventivo que se ha expuesto en esta práctica y poder mejorar las inspecciones y la información contenida en este documento.

5. Análisis de Vibraciones en Cajas Multiplicadoras y Generadores, aplicado a fallas en rodamientos y engranajes en Generadores Eólicos Neg Micon NM 750.

5.1 Definición del Problema

Al inicio de la práctica, la empresa Neg Micon ya había realizado análisis de vibraciones en las cajas y los generadores. No obstante, esa información nunca llegó a manos de la empresa.

Por ese motivo y por la dificultad de detectar problemas en condiciones tan difíciles, además de las particularidades vibratorias de este tipo de tecnología, la empresa Aeroenergía decidió iniciar un programa de Análisis de Vibraciones aplicado a los rodamientos de los generadores, a los engranes y rodamientos de las cajas multiplicadoras y los rodamientos del rodamiento principal.

La idea original era utilizar el equipo de la Escuela de Mantenimiento del Instituto Tecnológico de Costa Rica (CMVA 55 Microlog). Sin embargo, el equipo no estaba en buenas condiciones. Por ello, la reparación, la espera y el pago de una póliza por parte de Aeroenergía fueron necesarios.

Además, no existía en la Escuela alguien anuente a explicar el uso correcto del software ni de la toma de mediciones, por lo cual se tuvo que aprender todas las partes del proceso del Análisis de Vibraciones. No obstante, se debe resaltar la participación de los profesores Eligio Astorga, Juan Carlos Miranda y Manuel Mata, todos de la Escuela de Mantenimiento, en la revisión del proyecto.

5.2 Aislamiento de Señales externas a los elementos por analizar

Las turbinas Neg Micon NM750 (como las presentes en Aeroenergía) poseen una serie de amortiguadores laterales en la parte trasera de la góndola, amortiguadores en los apoyos del Generador, amortiguadores en los apoyos de la Caja Multiplicadora y amortiguadores en los acoples flexibles que unen los ejes de la máquina.

Al realizar el análisis de vibraciones se supone que este conjunto de amortiguadores logrará impedir que las vibraciones del vaivén de la torre, las aerodinámicas propias del aspa, las producidas por otras máquinas en el entorno y las producidas por fluctuaciones eléctricas instantáneas interfirieran en gran medida con las propias de las fallas de los mecanismos. No obstante, se sabe que esto no es posible. Para remediarlo no queda más que la experiencia que permita discernir las señales que son causadas por fallas posibles de aquellas que son producidas por agentes externos.

5.3 Análisis de Vibraciones en la Caja

5.3.1 El Problema de Analizar Vibraciones en cajas.

Las Cajas Multiplicadoras de Flender PEAC 4300.4 son máquinas muy compactas y con gran cantidad de elementos rodantes. Esto le suma complejidad al análisis de vibraciones por la gran cantidad de ruido en las señales vibratorias de los múltiples elementos y por tener relativamente poca masa en la cual disipar las vibraciones.

En los programas de Análisis de Vibraciones quien dicta los patrones admisibles de vibración en Aceleración y Enveloping es la empresa fabricante a través del estudio de su propio producto. No obstante, al solicitar información las empresas Flender y Neg Micon han presentado datos insuficientes o de dudosa aplicación.

De ahí que parte del problema de no poder determinar posibles fallas con certeza en los primeros meses del Análisis de Vibración, se debiera a que el personal debe aprender por su cuenta cómo funciona la máquina y cómo se comportan sus vibraciones. El funcionamiento promedio de los mecanismos en diversos puntos se ha estimado por medio de una tabla de Excel y un sistema de promedios simples. Esta hoja se observa en el Anexo 12.

5.3.2 Información adquirida. Verificación, estudio y consecución de datos restantes.

La información facilitada por la empresa Flender se encuentra en el Anexo 19.

La empresa Flender no envió ningún tipo de confirmación de que esos datos fueran aplicables a las Cajas Multiplicadoras de Aeroenergía. El problema principal es que en Europa, con un sistema eléctrico de 50 Hz, las cajas giran a 1510 rpm en la etapa de salida. En Costa Rica, las cajas giran a 1812 rpm. Ese aspecto cambia considerablemente las frecuencias.

5.3.2.1. Rodamientos

En el caso de los rodamientos de la caja, las frecuencias fueron calculadas para 1812 rpm y sus armónicas fueron estimadas. Las tablas con la información reacondicionada se muestra en el Anexo 20. No obstante, debe agregarse que estos datos son dudosos. Hace algún tiempo, las cajas empezaron a fallar a nivel mundial y con ellas, las cajas de Aeroenergía sufrieron un cambio en algunos rodamientos. En las siguientes etapas, Aeroenergía debe procurar verificar los datos de vibraciones con la empresa Flender.

Además, los rodamientos en la caja fueron demarcados con letras. Estas letras se observan en el diagrama de la caja que se observa en el Anexo 22.

5.3.2.2. Engranajes

Las frecuencias de los engranajes brindados por la empresa Flender fueron reacondicionados. Estos datos se muestran en el Anexo 21.

Para este tipo de caja se hace un análisis adicional en el Anexo 23. Este análisis determina la frecuencia de giro en los piñones de la caja por el Método Analítico de Tabulación.

5.3.3. Selección de puntos en la caja.

Los puntos en la caja que se muestran en el Anexo 22 fueron escogidos para los siguientes fines. El punto 1 monitorea los piñones planetarios, la rueda sol, la rueda de la carcaza y los rodamientos B C e I. El punto 2 monitorea los mismos aspectos que el punto 1.

El punto 3 sensa el rodamiento A. El punto 4 monitorea los rodamientos G y D y los engranajes en la etapa intermedia. El punto 5 sensa los rodamientos G y F. El punto 6 determina las vibraciones en D y E y en la etapa final de velocidad.

El punto 7 determina el desalineamiento o los problemas de vibración axial.

El punto 20 sensa las vibraciones del rodamiento H y los engranes de la etapa intermedia. El punto 21 determina las vibraciones en los rodamientos E y F y las fallas en la etapa de salida del reductor.

5.4 Análisis de Vibraciones en los Generadores

5.4.1 El Problema de Analizar Vibraciones en Generadores

El principal problema en los generadores Elin ha sido la falta de respuesta de la empresa sobre datos de Análisis de Vibraciones. A raíz de la falta de información, los cálculos de las frecuencias de falla de los rodamientos del generador fueron realizados en el Anexo 24.

Además, se procedió a realizar un cálculo del promedio de los valores globales en todos los puntos del generador para determinar un nivel estándar y normal de vibración en esos lugares. Esos valores pueden ser apreciados en la hoja de Excel que aparece en el Anexo 12.

5.4.2 Presentación de los datos de vibraciones para el Generador Elin

Finalmente, después de acondicionar los datos, las frecuencias de falla para el generador se presentan en el Anexo 25.

5.4.3. Selección de puntos

El sensor fue puesto en el generador de manera radial lateral en el punto10 para el rodamiento delantero y en el punto 11 para el rodamiento trasero. Además existe otro punto denominado 12 que toma los datos axiales del generador con tal de saber si tiene problemas en el eje.

Estos puntos pueden ser apreciados en el Anexo 26.

5.5. Selección de tipos de medición pertinentes

Según corresponda, en los puntos donde los elementos sensados giren a bajas velocidades, la medición será de Velocidad.

Cuando los puntos por medir reflejen datos de elementos con velocidades de giro considerables, o se esté en presencia de engranajes y rodamientos, se tomarán mediciones en Velocidad, Enveloping y Aceleración.

Cuando los datos del punto deban reflejar desalineaciones y problemas en el eje se tomarán mediciones por Velocidad.

5.6. Configuración final de todos los puntos en el Software Prism 4

Los puntos en Velocidad se configuraron de la manera presentada en el Anexo 27.

Los puntos en Enveloping han sido configurados como se muestra en el Anexo 28.

La configuración de los puntos en Aceleración se observan en el Anexo 29.

5.7 Sistema de Análisis de los datos.

En vista de que no existe información de severidad de aceleración o patrones normales de vibración proporcionada por los fabricantes de esta aplicación, se optó por el siguiente sistema: a lo largo de las mediciones en los diferentes puntos de la máquina se ha conformado una hoja de Excel donde se incluye los datos de los valores globales obtenidos de las últimas mediciones del Reporte del Software. El propósito de la hoja de Excel es tabular los datos para comparar todas las máquinas del parque y calcular un promedio simple de cada punto con la idea de tener un *estándar*.

Esa hoja de Excel se observa en el Anexo 12

5.7.1. Paso 1 del Análisis de Datos

Esa hoja debe ser actualizada con cada medición para mejorar el valor tomado como estándar de cada punto. Debe tenerse el cuidado de verificar que la expresión matemática es correcta.

5.7.2. Paso 2 del Análisis de Datos

En el paso 2 se debe llenar el formato del Anexo 13. Con ese formato se establecen los valores globales, se determina la severidad de esa medición, se compara con los valores promedio de la hoja de Excel. Finalmente, se determina si es necesario mirar los espectros de determinados puntos en busca de fallas. Se incluye un ejemplo desarrollado de este formato en el Anexo 15.

5.7.3. Paso 3 del Análisis de Datos

En el formato presente en el Anexo 14 se analizan los espectros. En la hoja se denota las frecuencias más relevantes, se vincula esas frecuencias a posibles fallas, se analiza el estado de las vibraciones en bajas y altas frecuencias de manera que se pueda determinar en qué etapa se encuentra la falla y se decida si es conveniente intervenir la máquina. El ejemplo está disponible en el Anexo 16.

5.8 Análisis de los datos colectados en la Caja de la Turbina 1

Los pasos 1, 2 y 3 del análisis de los datos para la turbina 1 se puede observar en los Anexos 17 y 18. Después del Paso 2 se decide observar los espectros de los puntos 4, 6, 10, 11 y 12. En el Paso 3 se analizan los espectros y se tabula las cualidades de los espectros para concluir si se debe intervenir la máquina o no.

5.9 Conclusiones sobre la Turbina 1

Las conclusiones sobre el Análisis de Vibraciones se escriben sobre el formato del Análisis de Espectros del Anexo 18. En el caso de la turbina 1, se concluyó que el problema con el eje debe ser intervenido. Probablemente, las vibraciones reflejen problemas de desalineación y para saberlo con certeza debe utilizarse equipo especial para desalineación. Después de un diagnóstico sobre el problema, debe procederse a solucionarlo. Las demás vibraciones deben seguir siendo monitoreadas para obtener conclusiones.

5.10 Sobre el estudio de vibraciones a 1210 rpm.

Las turbinas de Aeroenergía rara vez se conectan a 1210 rpm. El periodo en el que se realizó el estudio de práctica no coincidió con las temporadas de vientos bajos. De esta forma, todos los datos y las mediciones necesarias para hacer análisis de vibraciones con 1210 rpm no estuvieron disponibles.

5.11 Análisis costo-beneficio del Análisis de Vibraciones

En la práctica con Aeroenergía, el costo de obtener el equipo fue el pago de c60.000 (menos de $140) del monto de la póliza del seguro por daño. Además de ello, el tiempo de la práctica fue de 5 meses. El salario estimado del practicante es menor de $325 (c130.000) por mes. El costo por proyecto es una tercera parte de lo pagado al practicante más la póliza. Con ello se puede obtener el costo del Proyecto.

$$\text{Costo del Análisis de Vibraciones por cada rodamiento} = \frac{(\$140 + 5/3^* \$325)}{9 \times 2} = \$37.5$$

Para analizar el costo-beneficio del análisis de vibraciones se verá su efecto sobre la vida de un solo rodamiento en un generador. Según los cálculos de SKF, el 90% de los rodamientos como el usado en el generador duraría 6 años y 7 meses bajo las mismas condiciones, tal como se muestra en el Anexo 30. No obstante, los rodamientos de Aeroenergía no tienen una vida tan larga. El costo de cada rodamiento del generador es de $2500.

De esta forma, el programa de Análisis de Vibraciones *se justifica al extender la vida de cada rodamiento de generador en 1 mes y 5 días.* La razón es que un rodamiento tiene un costo por hora de $2500/ 57850 h ($0.0432/h). Con ello se obtiene el tiempo de retorno.

T de retorno por rodamiento = $37.5 / ($0.0432 / h) = 868 h = 1 mes, 5 días.

Esto se puede lograr fácilmente al determinar problemas en los ejes o rodamientos y proceder a lubricar o balancear. No obstante, este cálculo no estima los beneficios del análisis en la Caja Multiplicadora.

5.12 Conclusiones y recomendaciones

El Análisis de Vibraciones puede ser una herramienta muy útil para este tipo de tecnología en especial. Por esa razón es importante que se le de continuidad al proyecto aplicado a Rodamientos y Engranajes. No obstante, es recomendable extender el análisis de vibraciones con tomas de referencias de fase para determinar problemas en ejes; toma del HFD en los puntos más importantes de la Ruta y la toma del SEE para reconocer problemas de lubricación en los rodamientos del generador y los rodamientos de entrada y salida de la Caja Flender.

Por otro lado, se debe iniciar una evaluación más técnica de la desalineación en los generadores con el objetivo de corregir los problemas lo antes posible.

6. Programa de implementación de un Historiador de datos en los Aerogeneradores por medio de PLCs de comunicación

6.1. Definición del problema

El problema por resolver desde un inicio era la necesidad de tomar datos constantemente del proceso para que el Historiador se volviera una herramienta de decisiones administrativas. En el contrato con el ICE Aeroenergía se compromete a cumplir con cierta cantidad de energía cada mes. De no cumplirse ese monto, el ICE aplica sanciones. Por ello, un sistema de monitoreo de variables, permitiría a lo largo de los años hacer posible un estudio de las condiciones, predecir el comportamiento de ciertos rubros y disminuir la posibilidad de ser multados por incumplimiento de cantidad de energía.

La idea original del proyecto era conectar la red de controladores WP3000 de las turbinas con una computadora y que en ella el programa iHistorian de la casa fabricante General Electric grabara los datos más importantes. No obstante, esto no fue posible porque según los fabricantes de los controladores WP3000 (Mita Teknik) los sistemas no son compatibles con los OPC de General Electric.

Luego de la respuesta dada por Mita Teknik, se pidió una cotización a la empresa Electricidad Americana para que asumiera el diseño del proyecto. La idea entonces ya no era tomar los datos del controlador WP3000, sino conectar sensores (anemómetros, sensores de rpm y sensores de temperatura) extra y dispositivos (el dispositivo de Vibración Tac 84 y el relé de protección SEG) que no habían sido comunicados en el proceso y enlazarlos todos con un PLC para transferir datos a la Computadora y luego al programa iHistorian.

La empresa Electricidad Americana envió la solicitud a la representante SisFlex S.A. en México. Las empresas SisFlex y Electricidad Americana contestaron a la solicitud con una lista de software por un monto de $28,046.00 más impuestos (que no incluye el Hardware) (Anexo 31).

Los administradores de Aeroenergía consideraron que el proyecto no parecía justificable dados esos costos. Por ello, se buscó incrementar los beneficios del proyecto por medio de la inclusión en el proyecto de sensores de flujo y de nivel de aceite en las cajas. Estos sensores arrojarían alarmas en caso de que una fuga o obstrucción en el circuito de aceite ocurriera. Las fallas en el circuito hidráulico no son monitoreables en este momento por medio del sistema de Mita Teknik.

Cuando se pidió a SisFlex que asumiera la selección de los sensores de flujo y de nivel, la comunicación con ellos se perdió. De esa forma, todo el proyecto quedó en nuestras manos. Se consultó con la empresa de los Aerogeneradores Neg Micon sobre los sensores. Neg Micon contestó que en anteriores ocasiones ellos habían intentado sensar flujo y nivel de aceite en las cajas multiplicadoras sin buenos resultados.

Ante esta nueva negativa, se procedió a hacer requisiciones de sensores de flujo y nivel de aceite para dicha aplicación. Las empresas consultadas fueron Elvatron S.A., SPC y JRControles. De todas esas empresas, la única que dio respuesta fue Elvatron, sin embargo hasta la fecha no han encontrado una forma adecuada de medir dichos parámetros.

En ese momento, ya faltaba un mes para la conclusión del tiempo de práctica. Entonces fue cuando se procedió a consultar a la profesora Ana Lucía Morera, de la Escuela de Electromecánica, para solicitarle un PLC. Este, debía tener un módulo Modbus para los dispositivos de la turbina, una serie de entradas digitales y un módulo de entradas analógicas. El único PLC disponible tenía una tarjeta de comunicación RS-485 y entradas digitales. La conexión por Modbus y por vía analógica no era posible por medio de ese PLC y por ello, la implementación de gran parte del proyecto debía ser postergada.

Se procedió entonces a pedir el PLC a la Escuela de Electromecánica, a replantear los objetivos y a programar las siguientes etapas de desarrollo del Proyecto. El tiempo faltante para la conclusión de la práctica en el momento de la adquisición del PLC era de dos semanas.

6.2 Objetivos del Proyecto

Por medio de una PLC Mitsubishi FX_{1N} – 485 BD, se conectará:

a) El dispositivo de Vibración Tac 84C. Protocolo de Texto, ASCII. RS 485.

b) El relé de protección SEG. Modbus.

c) Anemómetro. Entrada Analógica.

d) PT100. Sensor de temperatura. Entrada Analógica.

e) Sensor de RPM. Entrada digital.

f) Sensor de flujo de aceite. Entrada analógica.

g) Sensor de nivel de aceite. Entrada analógica.

Al lograr manejar los diferentes dispositivos y sensores, el PLC debe conectarse por OPC Server al iHistorian. Por último, debe configurarse el programa iHistorian para almacenar los datos leídos.

6.3 Etapas en el desarrollo del Proyecto

6.3.1. Primera etapa de implementación

La primera etapa consta de:

a) Adquisición de información del PLC para programar el controlador.

b) Adquisición de información sobre la comunicación del dispositivo TAC 84c.

c) Conexión de la tarjeta de la comunicación RS 485 del PLC.

d) Propuesta de diagrama escalera para transferir datos del TAC 84c por RS-485.

e) Diagrama escalera para manipular la información del sensor de RPM.

f) Propuesta de sensor de nivel de aceite.

g) Propuesta de sensor de flujo de aceite

f) Cotización de PLC Mitsubishi FX_{1N}-485 DB, con dispositivos de entradas analógicas, Módulo Modbus y tarjeta de comunicación RS 485.

g) Desplegar los datos comunicados en un cuadro.

6.3.2. Segunda etapa de implementación

La segunda etapa consta de:

a) Adquirir el equipo de PLC con los módulos requeridos.

b) Adquirir un sensor de nivel de aceite en la caja multiplicadora.

c) Adquirir un sensor de flujo de aceite en la entrada de la caja multiplicadora.

d) Adquirir el módulo de comunicación Modbus del relé de protección SEG.

e) Comunicar vía Modbus el relé SEG con el PLC.

f) Comunicar los PT100 y anemómetros al PLC, en las entradas analógicas.

g) Desplegar los datos comunicados en pantalla.

6.3.3. Tercera etapa de implementación

La tercera etapa consta de:

a) Comunicar el sensor de nivel de aceite con el PLC.

b) Comunicar el sensor de flujo de aceite con el PLC.

c) Estudiar la configuración de los datos en el demo del programa iHistorian.

6.3.4. Cuarta etapa de implementación

La cuarta etapa consta de comunicar todos los datos del PLC al Historiador y configurar el programa para colectar datos.

6.4. Resultados de la primera etapa de desarrollo del proyecto.

6.4.1 Información técnica de programación del PLC

Se ha obtenido el manual de programación II en papel. Este manual se aplica a las versiones de Mitsubishi FX 1S, FX 1N, FX2N y FX2NC y por lo tanto sirve para la programación del PLC en las siguientes etapas.

Además de este manual se adquirió una serie de archivos digitales que se observan en el Anexo 32. Sin embargo, al leer los manuales se llega a la conclusión de que falta la continuación del manual S-080006-B (Manual del Módulo de comunicación Q), que tiene la solución definitiva de la comunicación del TAC 84c en el Capítulo 13: Comunicación con código ASCII. Ese manual es el SH-080007-B.

6.4.2. Información sobre el dispositivo TAC 84c

En el Anexo 33 se observa el único documento técnico que los diseñadores del Dispositivo TAC 84 han facilitado.

En ese archivo se muestra que la comunicación del TAC 84c está cableada para comunicación de un par en 485. El pin de 485 A, enlaza internamente el envío y la recepción de datos A; el pin 485 B es el nodo del envío y la recepción de datos de B.

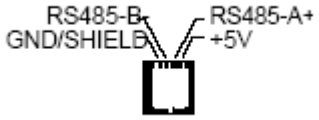

Figura 6.4.2.1. Comunicación RS-485 del TAC 84c[13]

Además de ello, se sabe que transfiere datos a 9600 baudios, que se comunica por protocolo de texto ASCII, que su Identificador de Nodo es 1 y que al encender despliega en pantalla un ID de Programa 10011101.

[13] Tomado del archivo TAC 84c del Anexo 33.

6.4.3. Conexión de la tarjeta de comunicación FX_{1N} - 485 BD

Como el TAC 84c está internamente cableado a un par, la tarjeta que recibe la señal también debe estar conectada para comunicación como un par agrupado de terminales de send y receive. En la figura siguiente se observan las conexiones y la resistencia necesaria para realizar dicha configuración.

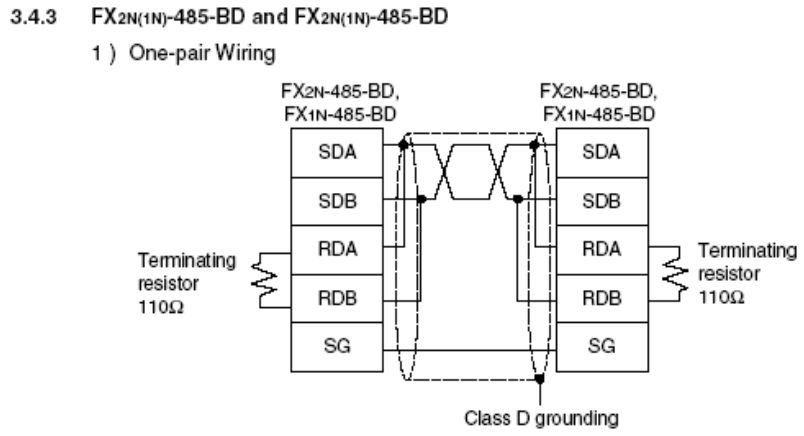

Figura 6.4.3.1. Conexión de la tarjeta de comunicación 485 en el PLC[14]

6.4.4. Propuesta de diagrama escalera para comunicar el TAC 84c por RS-485.

Debido al limitado tiempo que quedaba entre la adquisición del PLC, la información y el fin de la práctica la comunicación serial no pudo ser desarrollada plenamente en esta etapa del proyecto. No obstante, sí queda una idea clara de cómo desarrollar la comunicación.

[14] Tomado del archivo JY992D69901-E.pdf que aparece en el Anexo 32.

En el Manual Digital Completo de Programación (que se ofrece en el Anexo 32) y en el Manual en papel se puede observar la Función RS desarrollada por Mitsubishi para la comunicación de Dispositivos Externos vía Serial. Esta información se encuentra en el apartado FNC 80 – 89: External FX Serial Devices en 5-94; o bien en la hoja 236 del documento en formato PDF.

6.4.5. Diagrama escalera para comunicar el sensor de RPM

La información del sensor de RPM no se presenta en el Anexo 31. Pero se sabe que envía pulsos de 24 Volt tres veces por cada vuelta del rotor (tiene tres aldabas reflectoras distribuidas a 120°).

Con ello, se construyó el diagrama de escalera presente en el Anexo 34.

6.4.6. Propuesta de sensor de nivel de aceite.

Sobre este aspecto, la empresa Neg Micon fue consultada. Ellos informaron haberlo intentado sin resultados en el pasado. Pese a ello, Aeroenergía está interesada en realizar el trabajo. Para esto hay que escoger un sensor que se adapte a las condiciones de temperatura, presión y viscosidad del aceite de la caja (la hoja de datos del aceite de la caja se ve en el Anexo 35).

La temperatura del aceite es de 70°C y la presión es siempre menor a 16 bar. La idea es utilizar el espacio donde actualmente existe una mirilla. El esquema se observa en el Anexo 36.

En la imagen se observa que la actual mirilla tiene una raya que indica el nivel deseable de aceite. El nivel mínimo (Alarma por bajo nivel) es a 1 cm por debajo de esa raya. El máximo nivel (Alarma por exceso de aceite) debe estar a 1cm por encima de la raya roja. Además, en el Anexo se observa un archivo con una propuesta de tecnología a utilizar. Son sensores analógicos de nivel. Este sensor estaría en un contenedor sujeto a las tomas de la mirilla actualmente instalada en la caja. El sensor debe estar diseñado para soportar las condiciones de operación. Una ventaja de estos sensores de nivel es su reducido costo.

6.4.7. Propuesta de sensor de flujo de aceite

De la misma forma en que luego de que se preguntó sobre el sensor de nivel en la caja, la empresa Neg Micon aseguró haber intentado poner un sensor de flujo en circunstancias parecidas sin resultados.

Al buscar una solución, se encontró que la empresa Hydac que fabrica las bombas que suplen aceite a la caja fabrica sensores de flujo para la bomba utilizada en las turbinas. En una ocasión la empresa Hydac fue consultada sin contestación. El catálogo general del sensor se muestra en el Anexo 37.

6.4.8. Cotización de PLC Mitsubishi FX_{1N}-485 DB, con dispositivos de entradas analógicas, Módulo Modbus y tarjeta de comunicación RS 485.

La cotización pedida al Ing. Alexander Agüero de la empresa Hi-TEC incluye

a) PLC FX1N-14MR con 8 entradas de 24 Vdc, 6 salidas relé, alimentación de 120 V: 300,00$

b) Tarjeta de comunicación RS-485 FX1N-485-BD: 56,00$

c) Cable de programación SC09: 222,00$

d) Software de programación original: 617,00$

TOTAL: $1.195,00

I.V: $155,35

TOTAL I.V.I: $1.350,00

La inclusión de un módulo analógico de 2 canales, en el rango de 4 a 20 mA le añadiría $216 más impuesto a la cotización inicial ($244). El monto final del equipo es de $1594. La entrega es inmediata. Este conjunto de elementos contiene todo lo necesario para desarrollar todas las etapas del proyecto. Un costo adicional se debería a los sensores de nivel y de flujo, y el módulo Modbus del Relé SEG. Los elementos adicionales (sensores principalmente) podrían costarle al proyecto unos $800 más, para un posible total de $2394.

6.4.9. Despliegue de datos en pantalla

Los PLC Mitsubishi pueden desplegar los datos con el comando Entry Data Monitor o Monitoreo de entrada de datos. Allí se puede vigilar cualquier Buffer o dispositivo del PLC.

6.5. Análisis de Costos del Proyecto

En este documento se ha explicado que la producción promedio por turbina por hora es de $45. Se puntualizó que el costo de los materiales del proyecto podría estar valorado en $2394. A este dato se suma el costo de la práctica de especialidad (estimado en $541) y el costo del software iHistorian (con valor de $4163).

De esa forma se obtiene que el proyecto se pagaría con un total de 6 días, 13 horas, en total de turbinas detenidas, como se muestra a continuación.

$$\$2394 + \$541 + \$4163 = \$45 \times \text{Horas de turbina detenida}$$

$$H = 157 \text{ horas, } 44 \text{ minutos} = 6 \text{ días, } 13 \text{ horas.}$$

Ese tiempo distribuido entre las 9 turbinas corresponde a 17 horas, 30 minutos. Esas 17 horas, 30 minutos corresponden al 11% de tiempo de paro del parque en marzo del 2004 (mes en el cual el tiempo de paro fue de 157,5 horas). De esa forma, se pagaría la inversión si se logra evitar un 11% de las horas de paro, por nueve meses.

No obstante, este proyecto está en capacidad de evitar gastos por reparaciones de bombas, por deterioro de la góndola, por deterioro en la caja y por sanciones ante el incumplimiento de la cuota de energía prometida al ICE al mes. Esos son aportes extra que no están cuantificados en la justificación y que disminuyen el tiempo de retorno de la inversión.

6.6. Conclusiones

La principal conclusión es que el proyecto implica una inversión de tiempo importante y su realización es posible. Además se trata de un proyecto costoso y con un alto nivel de complejidad técnica. Se ha demostrado que muchos de los elementos necesarios para desarrollar el proyecto deben ser comprados y seleccionados cuidadosamente, así como que la programación del PLC es un aspecto que amerita de tiempo.

6.7 Recomendaciones

Antes de proceder con las siguientes etapas de desarrollo debe encontrarse la solución a los sensores de flujo y de nivel de aceite y debe poderse configurar experimentalmente la comunicación a la computadora con un sistema de PLC que incluya entradas Modbus, analógicas, digitales y vía puerto serial para asegurar desde el inicio las ventajas de la inversión.

Se recomienda la continuidad del proyecto y la evaluación meticulosa de cada etapa en el desarrollo de la idea.

Máquina AEROGENERADOR	**Parte** Torre de meteorología	**Código** AE -11

Número	Inspección Hora de inicio: Hora de salida:	T (min)	Ok	X
	Subparte Sensores, cajas y los cables			
01 P10	Revisión y lubricación de los sensores móviles con rodamientos cada 6 meses Anotación:			
02 P10	Revisar el estado de los cables y las cajas, su desgaste y corrosión cada 6 meses. Anotación:			
	Subparte Controladores WP1000			
03	Entrevistar el controlador para corroborar que está funcionando bien. Corroborar que la comunicación está en buen estado. Cada 6 meses. Anotación:			
04 P10	Revisar que los cables estén firmemente conectados. Cada 6 meses Anotación:			
05 P10	Revisar visualmente el interior del controlador. No deben verse dispositivos corroídos o parcialmente quemados. Cada 6 meses Anotación:			
	Subparte Estructura			
06 P10	Revisión de la corrosión y la pintura cada 6 meses Anotación:			
07	Resocar las tuercas de los cimientos, verificar las soldaduras, resocar y verificar el estado de los anclajes y los cables. Cada 6 meses Anotación:			

Tabla A.5.12. Hoja de inspección de Inspecciones generales B

Empresa AEROENERGIA Mantenimiento Preventivo	HOJA DE INSPECCION	**B**

Máquina AEROGENERADOR	**Parte** Inspecciones generales	**Código** AE-T01-12

Número	**Inspección Hora de inicio: Hora de salida:**	**T (min)**	**Ok**	**X**
01	Corroborar que la góndola se posicione de cara a la dirección del viento. Visualmente Anotación:			
02	Revizar el nivel y el tipo de ruido y vibración de las máquinas trabajando. Auditivo. Anotación:			
03	Revizar el frenado de disco como único dispositivo de frenado. Anotación:			
04	Revizar el frenado aerodinámico como único dispositivo de frenado. Anotación:			
05	Controlar e imprimir los setpoints. Anotación:			
06	Imprimir los errores Anotación:			
07	Imprimir la curva de potencia Anotación:

Nota: La programación del Gantt se realizó estimando la disponibilidad de un solo técnico que trabaja 6 horas.

No obstante, en la Empresa Aeroenergía existen 3 técnicos y trabajan 8 horas por día.

Este tipo de estimación fue necesario para evitar repercusiones por ausencia de algunos técnicos,

falta de disponibilidad de herramientas o piezas, asignación repentina de tareas correctivas o la

necesidad de un técnico para otras labores.

MANTENIMIENTO

Nombre Empleado: **Faddy Chaves Barahona**

Semana **19/04/2004 al 25/04/2004**

	CODIGO	HORAS		TRABAJO
LUNES	**AETB08**	07:00 a.m.	11:00 a.m.	Revicion de las turbinas T8, T9, T6.
				Visita del TEC (atencion)
19	**AEEO01**	02:00 p.m.	04:00 p.m.	Limpieza del jardin frente al edificio
MARTES	**AETB08**	07:00 a.m.	09:00 a.m.	Se recojieron extintores y descargaron por mantenimiento
		09:00 a.m.	02:00 p.m.	Vieje a Liberia a dejar los extintores
20				Cotizacion de herramienas en Cañas
		02:00 p.m.	03:30 p.m.	Inspeccion de la T6 (tips abierto)
MIERCOLES	**AETB08**	07:00 a.m.	03:30 p.m.	Trabajos en la T9 (cambio de la luz piloto, se desarrollo,
				inspeccion de la aspa (cable reventado), cambio de base fotocelda
21		03:30 p.m.		Viaje a Liberia por zapatos de personal
JUEVES	**AEBD02**	07:00 a.m.	04:00 p.m.	Se trabajo en la construccion del banco de trabajo .
				Solodadura,corte de maderas,fijamiento, puesta de prensa.
22				
VIERNES	**AETB08**	07:00 a.m.	08:30 a.m.	Se preparo herramienta para trabajo de la T8
	AETB08	08:30 a.m.	03:30 p.m.	Se le cambio el motor de guiñada de la T8
23				
SABADO				
24				
DOMINGO

MANTENIMIENTO

Nombre Empleado: **Faddy Chaves Barahona**

Semana **26/04/2004 al 02/05/2004**

	CODIGO	HORAS		TRABAJO
LUNES				Reporte de trabajos
	AEBD02	07:00 a.m.	11:00 a.m.	Limpieza y acomodamiento de herramientas
26	**AESCS05**	12:00: MD	04:00: PM	Se pusieron laminas de la casa de Salo (fibrolit)
MARTES	**AETB08**	07:00 a.m.	11:00 a.m.	Inspección de las turbinas T1, T3 con la gente de EMS
	AETB08			Se les cambio filtro de aceite, se bajaron los extintores y luz piloto
27				
MIERCOLES	**AEPR04**	07:00 a.m.	08:00: AM	Limpieza de la perrera
	AEEO01	08:00: AM	09:00: AM	Limpieza de jardín de frente al edificio y puesta de agua
28	**AEPR04**	09:00: AM	11:00: AM	Visita del veterinario por los perros
		11:00: AM	01:00: PM	Se soldó el carro de Don Carlos López
JUEVES	**AESCS05**	07:00 a.m.	09:00: AM	Riega de hervicidas en camino de la casa Salo
	AESCS05	09:00 a.m.	11:30: AM	Chapia de el solar de la casa de Salo
29		12:30: PM	01:30: PM	Se trajo motor de guiñada de la torre T8
	AEBD02	02:00: PM	04:00: PM	Se trabajo en la recuperación del repuesto motor guiñada
VIERNES	***AETB08***	07:00 a.m.	09:00: AM	Termografia a panel de potencia de la Turbinas
	AETB08	09:00 a.m.	11:00: AM	Limpieza de la base de las maquinas
30	**AEBD02**	11:00: AM	12:30: PM	Se trabajo en la recuperación del repuesto motor guiñada
	AETB08	01:30: PM	04:00: PM	Cambio de filtro de aire del extractor pequeño del panel y análisis
				vibración de la T8, T7 con Carlos Vargas

Trabajo limpieza maleza acceso a transformadores y cajas de registro.

DESCRIPCION DEL TRABAJO:
Limpieza de maleza alrededor de los transformadores de plataforma, y cajas de registro
Aplicar herbicida, y barrer maleza alrededor de cada transformador.

Codigo: **AETF07**

Agroveterinaria
Tilaran

Item	Descripción de materiales	Cant.	Costo/ unidad	Costo Total
1	Galones de bioquil	2	¢ 5,500.00	¢ 11,000.00

Total: **¢ 11,000.00**

Nota: Pago al crédito, factura 062309
Fecha 11/05/2004

Imágenes de las partes de la turbina

Anexo 11: Imágenes de la máquina

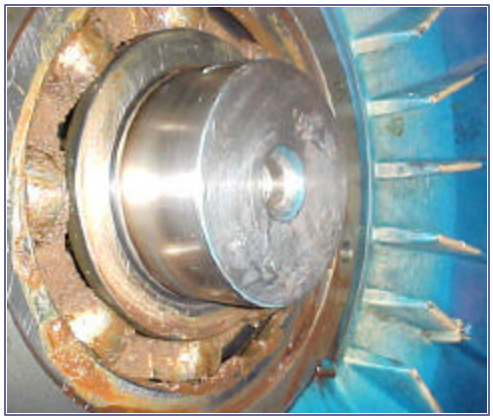

Fig. A11.1: Rodamiento trasero y delantero

Fig.A11.2: Caja de conexiones, cables de potencia, pernos de la tapa frontal del generador, manguera de entrada a la bomba

Fig. A11.3: Radiador de agua, conexiones de entrada y salida, purga, cable aterrizado

Fig. A11. 4: Bomba, motor, caja de conexiones del motor, pernos de sujeción del motor, purga manual, pernos de sujeción del Generador, contrapesos de la góndola, mangueras y uniones.

Fig.A11.5: Entrada y salida del agua al generador, contrapesos, motor y bomba, caja de conexiones del motor, pernos de sujeción del generador, agarraderas del generador

Fig. A11.6: Cables de potencia del generador, frenos de fricción de guiñada, motorreductores de guiñada, eje principal y su acople, plataforma de ascenso.

Fig. A11.7: Entradas y salidas de potencia del generador, caja de conexiones del generador, cable de sensor, manguera y unión del radiador del aceite de la caja

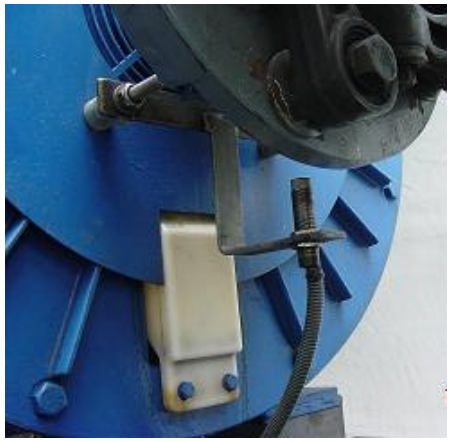

Fig.A11.8: Depósito de grasa del generador, sensores de velocidad, pernos del acople flexible y elementos de unión del acople, pernos del depósito de grasa, pernos de la tapa frontal del generador

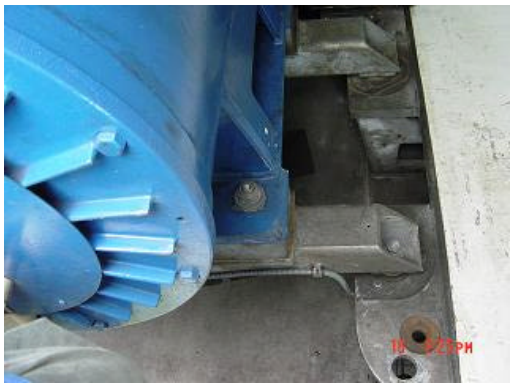

Fig. A11.9: Pernos, base y amortiguadores de sujeción del generador, cable del sensor, pernos de la tapa frontal

Fig.A11.11: Cables de la caja de conexiones al estator del generador, agarraderas del generador, caja de conexiones

Fig.A11.10: Tapa del radiador de agua y manguera de purga del generador

Fig.A11.12: Acople y eje del generador, pernos de tapa frontal, caja de conexiones, mangueras de entrada y salida de agua, radiador de aceite, purga de agua, agarraderas de instalación del generador.

Fig.A11.13:Disco de frenos, pernos de disco de frenos, pastillas de freno, bridas y pernos, acople flexible del generador

Fig.A11.14: Ejes, acople del generador, disco de freno, pernos de disco de freno, pastillas de freno, mecanismo de freno, pernos, prensas, brida con la caja, lightning brush, manguera de aceite, filtro de aceite

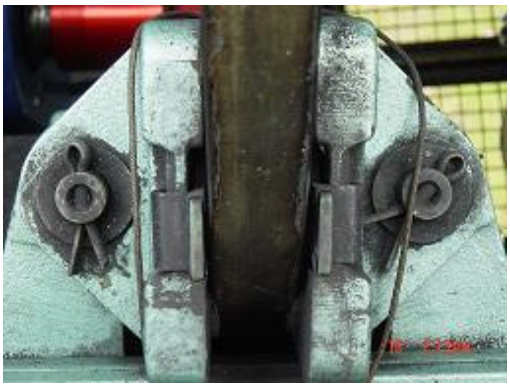

Fig.A11.15: Disco de freno, prensas, cable de sensor, pastillas

Fig. A11.16:Pernos de sujeción de mecanismos, tuercas de ajuste del mecanismo de freno, mecanismo en general

Fig.A11.17: Acumulador de aceite, uniones de aceite de freno, mangueras de aceite, pernos y estructura de sujeción de la bomba del freno, bomba de freno, mangueras de la bomba de freno, cableado de la bomba

Fig.A11.18: Caja de conexiones de la bomba, cables de señales, pernos de sujeción de la bomba, motor y bomba de freno, mangueras y uniones, vertedero de aceite.

Fig.A11.19: Pernos de ajuste del mecanismo de freno, prensas, pernos, acumulador del soft brake, pastillas de freno, cable de señal de desgaste del freno, disco de freno, acople flexible en el freno.

Fig.A11.20: Nivel de aceite de la bomba, bomba y motor de freno, pernos y estructura de sujeción de la bomba, vertedero de aceite, uniones y mangueras.

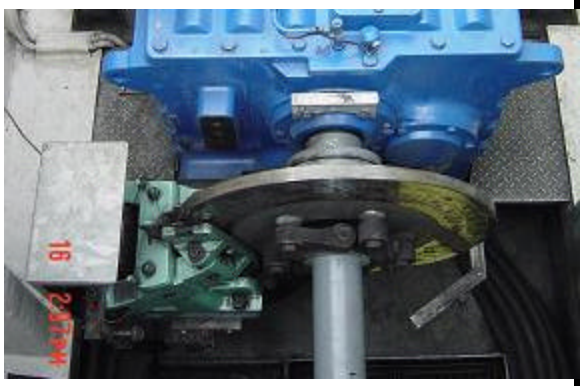

Fig.A11.21: Acople flexible en freno, pastilla de freno, lightning brush, caja, pernos y registros, eje, pastillas de freno, mecanismo de freno, brida del eje, PT100.

Fig.A11.22: Motor del ventilador, caja de conexiones del ventilador, rejilla del ventilador, aspas del ventilador, radiador, mangueras del radiador

Fig.A11.23: Slip Ring, aro sujetador de palanca de SlipRing, indicador de aceite de bomba de freno, motor y bomba de freno, mangueras de bomba de freno

Fig.A11.24: Slip Ring, aro sujetador de palanca de Slip Ring, medidor de aceite, cable de datos de Slip Ring, perno de sujeción trasero de Caja multiplicadora, bomba de frenos.

Fig.A11.25: Esfera de vibración, mangueras de aceite de caja, uniones, filtro de caja, electroválvula, válvula manual de purga

Fig.A11.26: Nivel de aceite en caja, pernos de registro trasero de la caja, PT-100, válvula manual de purga

Fig.A11.27:Bomba y motor de aceite de caja, mangueras de entrada y salida, cables de sensores, plataforma y pernos de sujeción de la bomba.

Fig.A11.**28: Slip Ring, aro de sujeción de Slip Ring, cable de datos, nivel de aceite, pernos de tapa trasera de la caja, bomba de freno.**

Fig.A11.29: Uniones y mangueras de aceite arriba de la caja, pernos de las tapas superiores de la caja, caja de control, disco de fr

Fig.A11.30: Pernos y acople con el eje principal, eje principal, pernos de tapa frontal de la caja, pernos de sujeción, placa eje y pernos del amortiguador, pernos de la tapa superior de la caja

Fig.A11.31: Pernos de tapa frontal caja, unión y mangueras de aceite, caja de control.

Fig.A11.32: Escobillas de descarga eléctrica, PT-100, Pernos de registro de la caja, pernos de la tapa superior, brida de unión con el freno, registro y pernos laterales, rejilla del elevador mecánico.

Fig.A11.33: Tablero de control, uniones y mangueras de aceite de la caja, registros y pernos superiores de la caja, escobilla de descarga eléctrica, registros y pernos traseros de la caja, disco de freno, acople de disco de freno, motores de guiñada, pernos de sujeción de la caja a la góndola.

Fig.A11.34:Tablero de control, pernos de la tapa superior de la caja, generador, mangueras de aceite de la caja

Fig.A11.35: Manguera de aceite de la caja, unión, electro válvula, filtro, estructura y pernos de sujeción del filtro.

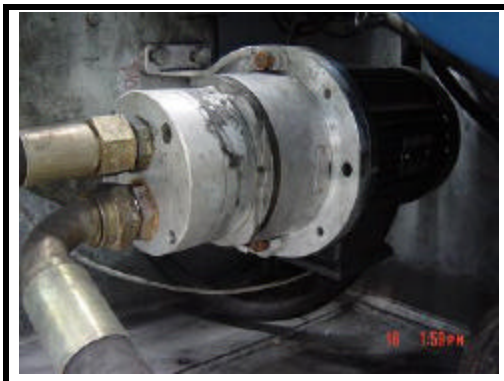

Fig.A11.36: Motor y Bomba de aceite, entrada y salida, pernos y marco de sujeción de la bomba, mangueras y uniones.

Fig.A11.37: Unión y mangueras de aceite, pernos y tapas de registros superiores, pernos de tapa superior, agarraderas de la caja

Fig.A11.38: Pernos de la tapa superior, pernos de registro superior, escobilla contra descargas eléctricas, pernos de sujeción del disco, pernos de la brida, mecanismos de freno, PT-100

Fig.A11.39: pernos y acople con el eje principal, pernos de la tapa frontal, freno de guiñada.

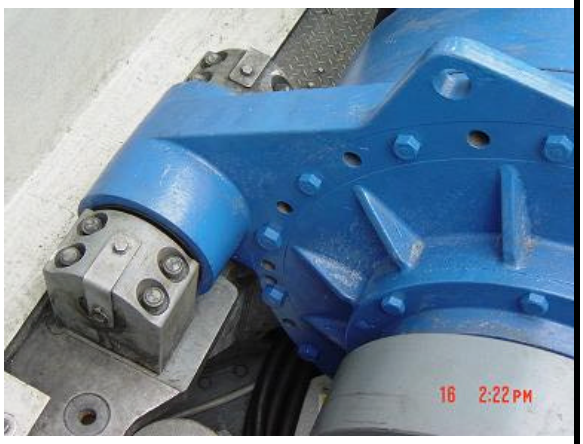

Fig.A11.40: Pernos de sujeción de la caja con el amortiguador; pernos, placa metálica y eje del amortiguador; pernos de la tapa frontal de la caja, agarradera.

Fig.A11.41: Pistón, acumulador, electro válvula.

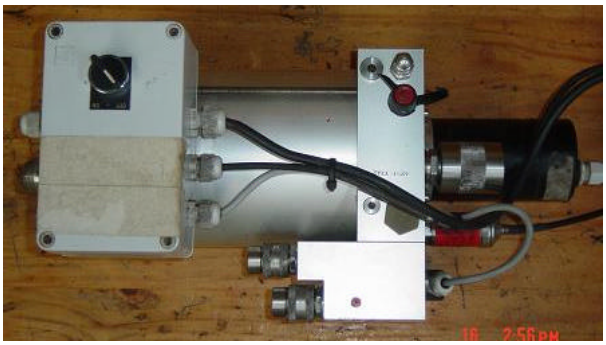

Fig.A11.42: Estación hidráulica, caja de conexiones, cables de control y de potencia, entradas y salidas de aceite, bomba y motor, sensores, vertedero de aceite, electroválvula

Fig.A11.43: Slip Ring, aro de sujeción de Slip Ring, cable de datos, nivel de aceite, pernos de tapa trase ra de la caja, bomba de freno.

Fig.A11.44: Entrada y retorno de aceite en el pistón

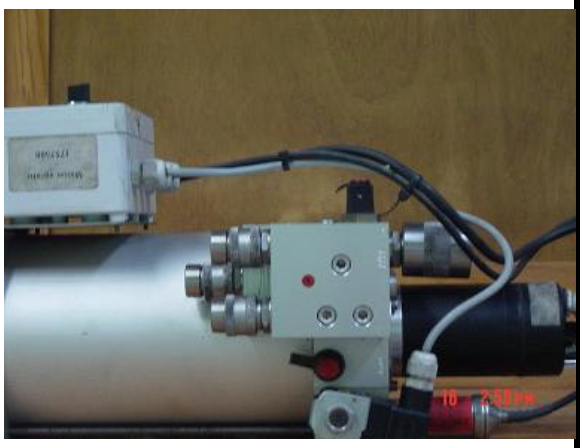

Fig.A11.45: Estación hidráulica, caja de conexiones, cables de control y de potencia, entradas y salidas de aceite, bomba y motor, sensores, vertedero de aceite, electro válvula

Fig. A11.46: Bola de vibraciones, sensor de palanca, asentamiento de la bola

Fig.A11.47: Grúa, gancho, brazo móvil

Fig.A11.48: Luz de navegación, veleta, anemómetro, sensor de luz

Fig.A11.49: Sujetador de compuertas, grúa, gancho, brazo móvil.

Fig.A11.50: Pernos de base de cimentación

Fig.A11.51: Gancho del Main Bearing, pernos del cubo, pernos de Main Bearing. Eje.

Fig.A11.52: Buje, las extensiones del cubo, aspas

Fig.A11.53: Registro en el buje, aspas, extensores del cubo, cubierta de la góndola

Fig.A11.54: Freno de fricción, tapa de freno, pernos de tapa

Fig.A11.55: Motor y reductores de guiñada, pernos de fijación a la torre, caja de conexiones, acople del motor, cable de potencia del motor

Fig.A11.56: Motor y reductor de guiñada, caja de conexiones, cable de potencia, acople del motor

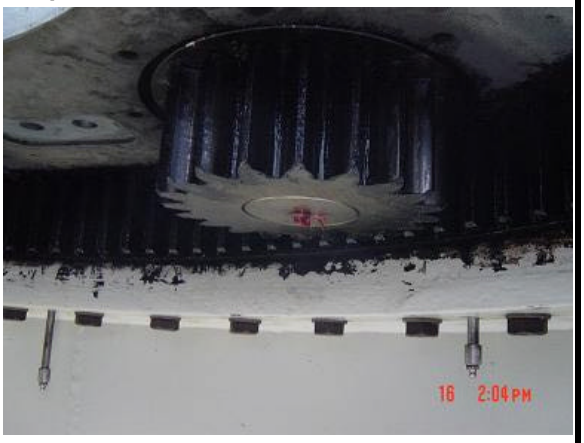

Fig.A11.57: Piñón y rueda de guiñada, tapa del pinón

Fig.A11.58: Tapa inferior al piñón con tornillos avellanados

Fig.A11.59: Disco y sensores de guiñada, pernos de fijación del freno a la torre, mecanismo de freno

Fig.A11.60: Veletas, anemómetros, sensor de luminosidad, luces de navegación aérea, pararrayos

Semana No:	Anotaciones generales: datos insuficientes. Tendencia a falla en Bearing delantero.
Tomó las mediciones: Carlos V.	Analizó los datos: Carlos V.

Conclusiones: Gran cantidad de vibraciones en 30 Hz. Problemas en el eje.

Posibles fallas:
A: Pista interior del Rodamiento
B: Pista exterior del Rodamiento
C: Elementos Rodantes
D: Canasta
E: Desalineación, Desbalance, eje torcido; o demás problemas con el eje.
F: Problemas en los dientes de los engranajes.

Anexo 23: Frecuencia de giro en los piñones de la caja por el Método Analítico de Tabulación.

En la siguiente figura se muestra una imagen de la Caja Flender PEAC 4300.4

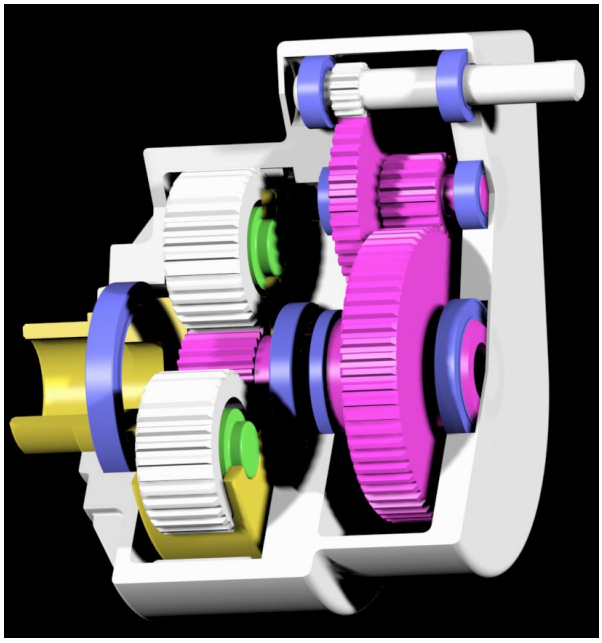

Figura.A.23.1. Distribución interna de la Caja Multiplicadora[17]

Para una configuración planetaria igual a la presentada por la Caja Flender se presenta la tabla básica del Método de Tabulación[18].

[17] Tomado de la Presentación de las mejoras en las Cajas Multiplicadoras
[18] Esta tabla fue tomada del libro Mecanismos y Dinámica de Máquina. Hamilton H. Mabie y Charles F. Reinholz.

Tabla A.23.1. Tabla de cálculos por el método de Tabulación

	Corona	Rueda sol	Piñón Planetario	Brazo transmisor
Movimiento con el Brazo relativo al bastidor	+1	+1	+1	+1
Movimiento relativo al brazo	-1	+ N1/N2	- N1 / N3	0
Movimiento total relativo al bastidor	0	1 + (N1/N2)	1 – (N1/N3)	+1

De esta forma, se obtienen las velocidades de cada elemento, sabiendo que se cuenta con 68 dientes en la corona de la carcaza, 26 dientes en el piñón planetario, 16 dientes en la rueda sol, que la relación de velocidades en la etapa intermedia es 24.04 y la relación de velocidades en la etapa de salida es 67.466.

Tabla A.23.2. Tabla de velocidades y frecuencias de los ejes de la Caja Multiplicadora

Velocidades de giro de los ejes en la Caja			
Velocidad en el brazo de entrada	i = 1	26 rpm	0.43 Hz
Velocidad en el piñón planetario	i = -1.615	42 rpm	0.7 Hz
Velocidad en la rueda sol	i = 5.25	136.5 rpm	2.275 Hz
Velocidad en la etapa intermedia	i= 24.04	625 rpm	10.41 Hz
Velocidad en la etapa de salida	i = 67.466	1812 rpm	30.2 Hz

Anexo 27: Configuración de las mediciones de Velocidad

Tabla A.27.1. Configuración de las mediciones de velocidad

Configuración de mediciones de Velocidad		
Full scale	10 mm/sec	El máximo esperable de los datos de velocidad es 10 mm/sec. Después de ese valor, una falla es obvia.
Input mV/EU	100	Este es el valor del sensor original del equipo.
Detection	RMS	Las tablas de la Norma ISO 2374 están en RMS
Low Frecuency limit	2 Hz	El limites de baja frecuencia debe ser un valor bajo.
Save Data	FFT and Time	Al salvar los datos en modo FFT and Time, se toma en cuenta el valor de la señal en el tiempo y se obtienen mejores señales
AutoCapture	Always	Con el modo de captura de datos en Always se agilizan las mediciones
Frequency Type	Fixed Span	El tipo Order Track es especial para toma de fases. En esta ocasión, la toma de fase no se aplica.
Speed	136 RPM	Esta velocidad cambia conforme cambia el punto a medir.
Start Frequency	0 Hz	Se inicia en 0 Hz con tal de no perder las señales en bajas frecuencias.
Lines	400	El número de lineas recomendable es 400. Un valor menor implica menos capacidad de análisis, y un valor mayor implica una toma de datos más lento.
End Frecuency	4000 Hz	Este dato puede cambiar a partir de la velocidad del elemento monitoreado.
Storage Depht	12	Para planes de monitoreo de vibraciones a largo plazo este dato debe incrementarse.
Window	Hanning	Este parámetro se usa para medición generales.
Averages	3	El número de datos con el cual obtiene el promedio debe ser bajo para agilizar la medición y evitar medidas sobrecargadas.
Speed Ratio	1	

Volver

Anexo 28: Configuración de las mediciones de Enveloping

Tabla A.28.1. Configuración de las mediciones de Enveloping

Configuración de mediciones de Velocidad		
Full scale	25 gE	El máximo esperable de los datos de velocidad es 25 gE. Ese valor es exagerado y no debería pasar de 10 gE.
Input mV/EU	100	Este es el valor del sensor original del equipo.
Detection	Peak to Peak	Usualmente los valores de Enveloping se miden de pico a pico.
Input Filter Range	500 Hz to 10 kHz	Para aplicaciones de 1800 rpm se usa el filtro 3 de Enveloping.
Save Data	FFT and Time	Al salvar los datos en modo FFT and Time, se toma en cuenta el valor de la señal en el tiempo y se obtienen mejores señales
AutoCapture	Always	Con el modo de captura de datos en Always se agilizan las mediciones
Frequency Type	Fixed Span	El tipo Order Track es especial para toma de fases. En esta ocasión, la toma de fase no se aplica.
Speed	1810 RPM	Esta velocidad cambia conforme cambia el punto a medir.
Start Frequency	0 Hz	Se inicia en 0 Hz con tal de no perder las señales en bajas frecuencias.
Lines	400	El número de líneas recomendable es 400. Un valor menor implica menos capacidad de análisis, y un valor mayor implica una toma de datos más lento.
End Frecuency	4000 Hz	Este dato puede cambiar a partir de la velocidad del elemento monitoreado.
Storage Depht	12	Para planes de monitoreo de vibraciones a largo plazo este dato debe incrementarse.
Window	Hanning	Este parámetro se usa para medición generales.
Averages	3	El número de datos con el cual obtiene el promedio debe ser bajo para agilizar la medición y evitar medidas sobrecargadas.

Anexo 30: Cálculo de la vida nominal del rodamiento del generador

El dato del L_{10h} es la vida alcanzada por al menos el 90% de una serie de rodamientos idénticos bajo las mismas condiciones y un buen funcionamiento.

El cálculo del L_{10h} para el rodamiento del Generador (6324/C3VL0241) es el que sigue:

$L_{10h} = (1000000/60 \times n) (C/P)^p$

Donde n = 1812 es igual a la velocidad en rpm de giro del eje; C = 208 kN es la capacidad de carga dinámica y corresponde a un dato de catálogo; P = 1.15 toneladas es la carga dinámica correspondiente al peso del rotor principal distribuido en dos apoyos (el peso del eje del generador es mucho menor que el del eje principal); y p = 3 para rodamientos de bolas (dato de catálogo).

Sustituyendo los valores:

$L_{10h} = (1000000/60 \times 1812) (208000N/1150 Kgf \times 9.8 N/Kgf)^3 = 57850 h = 6$ años, 7 meses.

INFORMACIÓN TÉCNICA

Requisitos Técnicos (**Mínimos**)

- IBM compatible, procesador Pentium III, 266 MHz, computadora personal o industrial que corra sobre plataforma Windows NT/2000/XP **en idioma inglés**.
- 96 MB RAM.
- 120 MB en disco duro.
- Drive CD-ROM.
- Monitor de color SVGA o mayor, con tarjeta de gráficos de 24 bit.
- Dispositivo apuntador.
- Puerto paralelo o USB.
- Adaptador de red: Compatible con Net-Bios ó adaptador de interfase de red TCP/IP.

INFORMACIÓN COMERCIAL

i. NOTAS

Condición de Entrega (Incoterm)	**LAB AEROPUERTO MÉXICO**
Tipo de Moneda	Dólares Americanos
Forma de Pago	100% al ordenar
Tiempo de Entrega	2 a 3 semanas posteriores a la colocación de su orden de compra
Vigencia de la Oferta	30 días

- Si su pago es en Moneda Nacional, favor de considerar el Tipo de Cambio a la venta de ventanilla del día de pago.
- Favor de incluir en el precio el 15% del I.V.A.
- Al colocar su Orden de Compra le solicitamos nos anexe los datos del Usuario Final: Nombre de la empresa, dirección, teléfono y nombre del Contacto.

• SAFETY PRECAUTIONS •

(Always read these instructions before using this equipment.)

Before using this product, please read this manual and the relevant manuals introduced in this manual carefully and pay full attention to safety to handle the product correctly.
The instructions given in this manual are concerned with this product. For the safety instructions of the programmable controller system, please read the user's manual of the CPU module to use.
In this manual, the safety instructions are ranked as "DANGER" and "CAUTION".

⚠ DANGER	Indicates that incorrect handling may cause hazardous conditions, resulting in death or severe injury.
⚠ CAUTION	Indicates that incorrect handling may cause hazardous conditions, resulting in medium or slight personal injury or physical damage.

Note that the ⚠CAUTION level may lead to a serious consequence according to the circumstances. Always follow the instructions of both levels because they are important to personal safety.

Please save this manual to make it accessible when required and always forward it to the end user.

[Design Instructions]

⚠ DANGER

- See manuals of each data link for the operating status of each station when there is a communication error in the data link.
  There is the risk of an accident occurring due to output error or malfunctioning.
- When using the notification function, the pager receiver may not be contacted due to the frequency transmission status from the system setup environment and error on the receiver side.
  To ensure the safety of the PLC system, install a call circuit with a lamp display or buzzer sound.
- When performing the control of the PLC in operation (changing data) by connecting a peripheral devices to the CPU module or personal computer, etc. to the intelligent device module, configure an interlock circuit in a sequence program so the safety of the overall system is always maintained.
  Also when performing other controls of the PLC in operation (changing program and operation status (status control)), read this manual carefully and confirm if the overall safety is maintained.
  Especially, when this control is performed to a remote PLC from an external device, troubles that have occurred on the PLC side may not be able to immediately be handled if there is a data communication error.
  Define a troubleshooting agreement between external devices and the PLC CPU for data communication error occurrences, as well as construct an interlock circuit in the sequence program.
- Do not write data into the "system area" of the buffer memory of intelligent function modules.
  Also, do not use any "prohibited to use" signals as an output signal to an intelligent function module from the PLC CPU.
  Writing data into the "system area" or outputting a signal for "prohibited to use" may cause a PLC system malfunction.

[Design Instructions]

⚠ CAUTION

- Do not bunch the control wires or communication cables with the main circuit or power wires, or install them close to each other.
  They should be installed 100mm(3.9inch) or more from each other.
  Not doing so could result in noise that may cause malfunction.
- When using the module while values, such as buffer memory set values, are registered in the Flash ROM, do not turn off the power supply for the module loading station nor reset the PLC CPU.
  If the power supply for the module loading station is turned off or the PLC CPU is reset while any values are registered, the data contents in the Flash ROM become inconsistent and as a result the values must be set again in the buffer memory, etc. and reregistered to the Flash ROM.
  Also, this may cause failure and malfunction of the module.

[Installation Instructions]

⚠ CAUTION

- Use the PLC in an environment that meets the general specifications contained in the user's manual of the CPU module to use.
  Using this PLC in an environment outside the range of the general specifications may cause electric shock, fire, malfunction, and damage to or deterioration of the product.
- When installing the module, securely insert the module fixing tabs into the mounting holes of the base unit while pressing the installation lever located a t the bottom of the module downward.
  Securely fix the module with screws if it is subject to vibration during use.
- Tighten the screws within the range of specified torque.
  If the screws are loose, it may cause the module to fallout, short circuits, or malfunction.
  If the screws are tightened too much, it may cause damage to the screw and/or the module, resulting in fallout, short circuits or malfunction.
- Switch all phases of the external power supply off when mounting or removing the module.
  Not doing so may cause damage to the module.
- Do not directly touch the conductive area or electronic components of the module.
  Doing so may cause malfunction or failure in the module.

[Wiring Instructions]

⚠ CAUTION

- When turning on the power and operating the module after installation and wiring are completed, always attach the terminal cover that comes with the product.
  There is a risk of electric shock if the terminal cover is not attached.
- Perform correct pressure-displacement, crimp-contact or soldering for external wire connections using the tools specified by the manufactures.
  Incorrect connection may cause short circuits, fire, or malfunction.
- Attach connectors to the module securely.
- Be sure to fix communication cables or power supply cables leading from the module by placing them in the duct or clamping them.
  Cables not placed in the duct or without clamping may hang or shift, allowing them to be accidentally pulled, which may cause a module malfunction and cable damage.
- Before connecting the cables, check the type o f interface to be connected.
  Connecting or erroneous wiring to the wrong interface may cause failure to the module and external devices.
- Tighten the terminal screws within the range of specified torque.
  If the terminal screws are loose, it may result in short circuits or malfunction.
  If the screws are tightened too much, it may cause damage to the screw and/or the module, resulting in fallout, short circuits or malfunction.
- When removing the communication cable or power supply cable from the module, do not pull the cable. When removing the cable with a connector, hold the connector on the side that is connected to the module.
  When removing the cable connected to the terminal block, first loosen the screws on the part that is connected to the terminal block.
  Pulling the cable that is still connected to the module may cause malfunction or damage to the module or cable.
- Be careful not to let foreign matters such as sawdust or wire chips get inside the module.
  They may cause fires, failure or malfunction.
- The top surface of the module is covered with protective film to prevent foreign objects such as cable offcuts from entering the module when wiring.
  Do not remove this film until the wiring is complete.
  Before operating the system, be sure to remove the film to provide adequate heat ventilation.

[Startup/Maintenance Instructions]

⚠ CAUTION
• Do not disassemble or modify each module. Doing so could cause failure, malfunction injury or fire. • Switch all phases of the external power supply off when mounting or removing the module. Not doing so may cause failure or malfunction of the module. • Do not touch the connector while the power is on. Doing so may cause malfunction. • Switch all phases of the external power supply off when cleaning or retightening terminal screws and module installing screws. Not doing so may cause failure or malfunction of the module. If the screws are loose, it may cause the module to fallout, short circuits, or malfunction. If the screws are tightened too much, it may cause damages to the screws and/or the module, resulting in the module falling out, short circuits or malfunction.

[Operation Instructions]

⚠ CAUTION
• When performing the control of the PLC in operation (especially changing data, program, and operation status (status control)) by connecting a personal computer, etc. to the intelligent function module, read this manual carefully and confirm if the overall safety is maintained. Failure to perform correct operation s to change data, program, or the status may result in system malfunction, machine damage, or an accident.

[Disposal Instructions]

⚠ CAUTION
• When disposing of this product, treat it as industrial waste.

REVISIONS

* The manual number is given on the bottom left of the back cover.

Print Date	* Manual Number	Revision
Dec., 1999	SH (NA) 080006-A	First Printing
Oct., 2000	SH (NA) 080006-B	Add the contents of the function version B. Correction Contents, Entire manual (change MELSECNET/10H to MELSECNET/H), About Manuals, About The Generic Terms and Abbreviations, Product Configuration, Section 1.2, 1.2(8), 1.3 POINT, Section 2.2, 2.3, 2.5, 2.6, Section 3.1, 3.6, 3.9, Section 4.2, 4.4.1(2)(a)(Figure), 4.6(1), Chapter 5(all), Section 6.1.1, 6.1.3, 6.1.4, Section 7.1.1, 7.1.2, 7.2.2, Section 8.1, 8.2.1, 8.2.2, 8.3.1, 8.3.2, Section 9.2 to 9.7, Section 10.1.1, 10.2.1, 10.3.8, 10.3.18, Appendix 1.1(2), Appendix 2(all), appendix 3(2), Appendix 7, appendix 8 Addition Entire manual (add the explanation on MELSECNET/H remote I/O station), The Manual's Use and Structure, Section 2.1, Section 3.1(Table), Section 4.4.2(1)(d), 4.9.2, Section 8.3.2 POINT, Section 10.2.1 (7164H, 7E70H), Appendix 3(1)

INTRODUCTION

Thank you for purchasing the MELSEC-Q series PLC.
Before using the equipment, please read this manual carefully to develop full familiarity with the functions and performance of the Q series PLC you have purchased, so as to ensure correct use.
Please forward a copy of this manual to the end user.

Product Configuration A-23

1 OVERVIEW 1- 1 to 1-10

1.1 Overview of the Serial Communication Module 1- 1
1.2 Features of the Serial Communication Module 1- 2
1.3 About Added/Changed Functions in Function Version B 1-10

2 SYSTEM CONFIGURATION AND AVAILABLE FUNCTIONS 2- 1 to 2-12

2.1 Applicable Systems 2- 1
2.2 Combinations of PLC CPU and External Device, and Available Functions 2- 2
2.3 When Using the Remote Password Function of the QCPU 2- 5
2.4 When Using the Q Series C24 at a Remote I/O Station 2- 6
2.5 When Using the Q Series C24 under the Multiple PLC System with Several QCPUs (Function Version B) 2- 9
2.6 Checking the Function Version, Serial No., and Software Version 2-11

3 SPECIFICATIONS 3- 1 to 3-29

3.1 Performance Specifications 3- 1
3.2 RS-232 Interface Specification 3- 3
3.2.1 RS-232 connector specifications 3- 3
3.2.2 RS-232 cable specification 3- 5
3.3 RS-422/485 Interface Specifications 3- 6
3.3.1 RS-422/485 terminal block specifications 3- 6
3.3.2 RS-422/485 cable specifications 3- 7
3.3.3 Precautions when transferring data using RS-422/485 circuit 3- 8
3.4 Serial Communication Module Function List 3-11
3.5 Dedicated Instruction List 3-12
3.6 Utility Package (QSCU) Function List 3-13
3.7 List of GX Developer Setting Items for Serial Communication Modules 3-14
3.8 List of Input/Output Signals for the PLC CPU 3-15
3.9 List of Applications and Assignments of the Buffer Memory 3-17

4 SETTINGS AND PROCEDURES PRIOR TO OPERATION 4- 1 to 4-31

4.1 Handling Precautions 4- 1
4.2 Settings and Procedures Prior to Operation 4- 2
4.3 Part Names and Functions 4- 3
4.4 External Wiring 4- 4
4.4.1 Connecting the RS-232 interface (full-duplex communications) 4- 5
4.4.2 Connecting the RS-422/485 interface 4- 7
4.5 Settings for GX Developer 4-11
4.5.1 I/O assignment settings 4-11
4.5.2 Switch settings for I/O and intelligent functional module 4-12
4.5.3 The Intelligent function module interrupt pointer setting 4-18
4.6 Settings with the Utility Package (QSCU) 4-20
4.7 Individual Station Test 4-23
4.7.1 ROM/RAM/switch tests 4-23
4.7.2 Individual station loopback test 4-26
4.8 Loopback Test 4-28
4.9 Maintenance and Inspection 4-30
4.9.1 Maintenance and inspection 4-30
4.9.2 When mounting/dismounting the module 4-31

5 DATA COMMUNICATION USING THE MELSEC COMMUNICATION PROTOCOL 5- 1 to 5- 7

5.1 Data Communication Functions 5- 1
5.1.1 Accessing the PLC CPUs using the MC protocol 5- 1
5.1.2 Message format and control procedure for data communication 5- 2
5.1.3 PLC CPU setting for performing data communication 5- 2
5.1.4 Support for Multple PLC systems 5- 3
5.1.5 Support for the QCPU remote password function 5- 4
5.2 Utilizing the MX Component and MX Links 5- 6

6 DATA COMMUNICATION USING THE NON PROCEDURE PROTOCOL 6- 1 to 6-29

6.1 Data Reception from the External Device 6- 2
6.1.1 Receiving methods 6- 2
6.1.2 The receive area and the received data list 6- 6
6.1.3 Sequence program for data reception 6-10
6.1.4 Receive data clear 6-13
6.1.5 How to detect reception errors 6-16
6.1.6 Received data count and receive complete code settings 6-19
6.2 Sending Data to the External Device 6-21
6.2.1 Transmission methods 6-21
6.2.2 Arrangement and contents of the transmission area and the transmission data 6-22
6.2.3 Sequence program for transmission data 6-23
6.2.4 How to detect transmission errors 6-26
6.3 Data Communications Precautions 6-28

7 DATA COMMUNICATION USING THE BIDIRECTIONAL PROTOCOL 7- 1 to 7-26

7.1 Data Reception from the External Device 7- 2
7.1.1 Receiving methods 7- 2
7.1.2 Arrangement and contents of the receive area and the receive data 7- 4
7.1.3 Sequence program for data reception 7- 9
7.1.4 How to detect reception errors 7-12
7.1.5 Receive data clear 7-13
7.2 Sending Data to the External Device 7-14
7.2.1 Transmission methods 7-14
7.2.2 Arrangement and contents of the transmission area and the transmission data 7-15
7.2.3 Sequence program for data transmission 7-17
7.2.4 How to detect transmission errors 7-20
7.3 Processing when Simultaneous Transmission Performed During Full-Duplex Communications 7-22
7.3.1 Processing when simultaneous transmissions occur 7-22
7.3.2 Communication data processing when simultaneous transmissions occur 7-23
7.4 Data Communications Precautions 7-25

8 UTILITY PACKAGE (SW0D5C-QSCU-E) 8- 1 to 8-45

8.1 Functions Available with Utility Package 8- 2
8.2 Installing and Uninstalling Utility Package 8- 3
8.2.1 Usage precautions 8- 3
8.2.2 Operating environment 8- 4
8.3 Explanation of Utility Package Operation 8- 5
8.3.1 Operation overview 8- 5
8.3.2 Starting the intelligent function module utility
(displaying the [select parameter setting module] screen) 8- 9
8.3.3 Performing common utility operations 8-11
8.4 System Registration to Flash ROM 8-14
8.4.1 User frame registration 8-16
8.4.2 Data for modem initialization registration 8-17
8.4.3 Data for modem connection registration 8-18
8.4.4 Modem function system setting/registration 8-19
8.4.5 Transmission control and others system settings 8-20
8.4.6 MC protocol system setting 8-22
8.4.7 Non procedure system setting 8-23
8.4.8 Bidirectional system setting 8-24
8.4.9 PLC CPU monitoring system setting 8-25
8.4.10 Transmission user frame No. designation system setting 8-27
8.4.11 Resetting the buffer memory/flash ROM setting values to the default values 8-28
8.4.12 Flash ROM write allow/prohibit setting 8-28
8.5 Auto Refresh Settings 8-29
8.6 Monitor/Test 8-30
8.6.1 X · Y monitor/test 8-31
8.6.2 Modem function monitor/test 8-32
8.6.3 Transmission control and others monitor 8-34
8.6.4 MC protocol monitor 8-36

8.6.5 Non procedure monitor/test 8-38
8.6.6 Bidirectional monitor 8-39
8.6.7 PLC CPU monitoring monitor 8-40
8.6.8 Transmission user frame No. designation monitor 8-42
8.6.9 Monitor others 8-43
8.6.10 Display LED off and communication error information/error code initialization 8-45
8.7 Non Procedure Protocol Receive Data Clear 8-45

9 DEDICATED INSTRUCTIONS 9- 1 to 9-21

9.1 Dedicated Instruction List 9- 1
9.2 ONDEMAND Instruction 9- 2
9.3 OUTPUT Instruction 9- 5
9.4 INPUT Instruction 9- 8
9.5 BIDOUT Instruction 9-11
9.6 BIDIN Instruction 9-14
9.7 SPBUSY Instruction 9-17
9.8 CSET (Receive data clear) 9-19

10 TROUBLESHOOTING 10- 1 to 10-39

10.1 Checking the Status of the Serial Communication Module 10- 1
10.1.1 Checking the LED ON status, communications error status, and switch setting status of the serial communication module 10- 1
10.1.2 Initializing error information of the serial communication module 10- 6
10.1.3 Reading the RS-232 control signal status 10- 9
10.1.4 Reading the data communication status (Transmission sequence status) 10-10
10.1.5 Reading the switch setting status 10-11
10.1.6 Reading the switch setting status for the current operation 10-13
10.2 Error Code Tables 10-15
10.2.1 QnA compatible 2C/3C/4C frame communications/Flash ROM access error code table 10-15
10.2.2 A compatible 1C frame communications error code table 10-21
10.2.3 Error code list while modem function is used 10-22
10.3 Troubleshooting by Symptom 10-24
10.3.1 Troubleshooting when "RUN" LED is turned OFF 10-26
10.3.2 Troubleshooting when "RD" LED does not blink even though an external device is transmitting a message 10-27
10.3.3 Troubleshooting when the Q series C24 does not return a response message even though an external device transmitted a message and the "RD" LED blinked 10-28
10.3.4 Troubleshooting when an external device transmitted a message and "RD" LED blinked, but the Read Request signal was not turned ON 10-29
10.3.5 Troubleshooting when communication error "NAK" generates 10-30
10.3.6 Troubleshooting when communication error "C/N" generates 10-30
10.3.7 Troubleshooting when communication error "P/S" generates 10-31
10.3.8 Troubleshooting when communication error "PRO." generates 10-32
10.3.9 Troubleshooting when communication error "SIO" generates 10-33
10.3.10 Troubleshooting when communication error "CH1 ERR.", "CH2 ERR." generate 10-34
10.3.11 Troubleshooting when communications is intermittently established and lost 10-35

10.3.12 Troubleshooting when data that cannot be decoded is transmitted and received 10-36
10.3.13 Troubleshooting when it is unclear whether the communication error cause is in the Q series C24 or an external device 10-37
10.3.14 Troubleshooting when data cannot be communicated with the GX Developer that supports serial communication modules 10-38
10.3.15 Troubleshooting when data cannot be communicated with the ISDN sub-address 10-38
10.3.16 Troubleshooting when constant cycle transmission does not operate normally 10-38
10.3.17 Troubleshooting when condition agreement transmission does not operate normally 10-38
10.3.18 Troubleshooting when data cannot be received by an interrupt program 10-38
10.3.19 Troubleshooting when data cannot be written to Flash ROM 10-39
10.3.20 Troubleshooting when the "ERR" LED is lit 10-39

CONTENTS

1 OVERVIEW 1- 1 to 1- 6

1.1 Overview 1- 1
1.2 Functions Added/Changed by Function Version B 1- 6

2 USING THE PLC CPU MONITORING FUNCTION 2- 1 to 2-29

2.1 Overview 2- 1
2.2 About the PLC CPU Monitoring Function 2- 2
2.3 Settings for Using the PLC CPU Monitoring Function 2-21
2.4 Precautionary Notes for Using the PLC CPU Monitoring Function 2-28

3 COMMUNICATIONS BY THE MODEM FUNCTION 3- 1 to 3-85

3.1 Overview 3- 1
3.2 System Configuration 3- 7
3.3 Specification 3-12
3.4 Start-up of the Modem Function 3-41
3.5 Sample Programs 3-73

4 RECEIVING DATA WITH AN INTERRUPT PROGRAM 4- 1 to 4- 5

4.1 Settings for Receiving Data Using an Interrupt Program 4- 2
4.2 Interrupt Program Startup Timing 4- 2
4.3 Reception Control Method Using an Interrupt Program 4- 3
4.4 Programming 4- 4

5 CHANGING SEND AND RECEIVE DATA LENGTH UNITS TO BYTE UNITS (WORD/BYTES UNITS SETTING) 5- 1 to 5- 2

6 CHANGING THE DATA COMMUNICATIONS MONITORING TIMES 6- 1 to 6- 9

6.1 No-Reception Monitoring Time (timer 0) Setting 6- 2
6.2 Response Monitoring Time (timer 1) Setting 6- 4
6.3 Transmission Monitoring Time (timer 2) Setting 6- 7
6.4 Message Wait Time Setting 6- 9

7 DATA COMMUNICATIONS USING DC CODE TRANSMISSION CONTROL 7- 1 to 7- 8

7.1 Control Contents of DTR/DSR (ER/DR) Signal Control 7- 2
7.2 Control Contents of DC Code Control 7- 3
7.3 Precautions when Using the Transmission Control Functions 7- 7

About Manuals

The following table lists the manuals relating to this product. Please order the desired manual(s) as needed.

Related manuals

Manual Name	Manual Number (Model Code)
Q Corresponding Serial Communication Module User's Manual (Application) This manual explains the specifications and operating procedures for the special module functions, the settings for use of special functions, and data-communication method for use with external devices. (sold separately)	SH-080007 (13JL87)
Q Corresponding MELSEC Communication Protocol Reference Manual This manual explains how the external devices read and write PLC CPU data through communication with the MC protocol using the serial communication module/Ethernet module. (sold separately)	SH-080008 (13JF89)

Conformation to the EMC Directive and Low Voltage Instruction

For details on making Mitsubishi PLC conform to the EMC directive and low voltage instruction when installing it in your product, please see Chapter 3, "EMC Directive and Low Voltage Instruction" of the User's Manual (Hardware) of the CPU module to use.
The CE logo is printed on the rating plate on the main body of the PLC that conforms to the EMC directive and low voltage instruction.

● How to use this manual

In this manual, details of the serial communication modules (QJ71C24 and QJ71C24-R2) are organized as shown below, according to their applications. Please use this manual using the contents below as a reference.

(1) To learn about features, functions and component parts

(a) To learn about features and functions
- Chapter 1 describes the features of the serial communication modules.
- Chapter 3 describes the common specifications and functions of the serial communication modules.

(b) To learn about the packed items and system-configured items
- The section prior to Chapter 1, "Product Configuration", describes the parts that are packed along with the serial communication module.
- Parts and components other than those packed with the module must be prepared separately by the user.

(2) To learn about processing required to start up the serial communication module

(a) To learn about the startup procedure
- Section 4.2 describes the general procedures prior to starting the operation of the serial communication module.

(b) To learn about the connection with the external devices
- Section 4.4 describes the connection methods for each type of interface.

(c) To learn about processing required prior to operation of the serial communication module
- Section 4.5 explains the parameter settings with GX Developer in order to use the serial communication module.
- Section 4.6 and Chapter 8 describe the settings from QSCU to perform the initial setting of the serial communication module.
  To change an initial value, follow the procedure described in Chapter 8.

(d) To check for failure in the serial communication module
- Section 4.7 describes the test of the individual serial communication module.

(e) To learn how to check for a connection error with the external devices
- Section 4.8 describes how to perform the individual module test and the loopback test using MC protocol-based communication.

* Details of the loopback test command are described in the reference manual.

A - 17

(3) To learn about data communication functions and detailed explanations

(a) To learn about the communication functions

- Section 3.4 describes an overview of the serial communication module functions.

(b) To learn about detailed explanations of the communication functions

- The basic communication methods are described in Chapters 5 to 7.
- Special functions are described in the User's Manual (Application).

(4) To learn about data communication functions and programming

(a) To learn how to read data from and written to the PLC CPU

- Data is read from and written to the PLC CPU with a communication function using the MC protocol.

＊ Details are described in the Reference Manual.

- Chapter 5 describes an overview of the basic communication support tool (CSKP) that supports communication using the MC protocol.

(b) To learn how to send and receive data between the PLC CPU and the external devices

- Data communication between the PLC CPU and the external devices is performed with a communication function using the non procedure protocol or the bidirectional protocol.
- Chapter 6 explains details of the communication functions and programming using the non procedure protocol.
- Chapter 7 explains details of the communication functions and programming using the bidirectional protocol.

(5) To learn how to check for error occurrences and take corrective actions

Chapter 10 describes troubleshooting, how to check for errors, and detailed explanations of error codes.

(6) To learn about functions that have been added or changed in function version B

- Section 1.3 lists the functions that have been added or changed as well as manuals that provide detailed explanations hereof.
- Appendix 1.1 provides a breakdown of the functions of Q series C24/QSCU by function version/software version.

- The structure of this manual

  The module's buffer memory stores default values that are used as initial settings to execute the data send/receive functions in order to communicate with the external devices.
  Data can be sent to or received from the external devices using these default values. However, it may be necessary to change the default values, depending on system specifications.
  This manual explains how to perform the initial settings in order to use each function of the utility package available for this module (SW0D5C-QSCU-E).
  When changing a default value for sending and receiving data to/from an opposite device, first see the section describing the applicable function to verify the initial setting item and setting value you wish to change, then change the default value as explained in Chapter 8.

A - 19

About The Generic Terms and Abbreviations

This manual uses the following generic terms and abbreviations to describe the serial communication modules, unless otherwise specified.

(1) Generic terms and abbreviations of relevant modules

In this manual, the following generic terms and abbreviations are used to indicate the PLC CPU and other modules used for the data-communication functions of the serial communication modules. Module model names are provided when relevant model names are needed to be shown.

Generic term/abbreviation	Description of generic term/abbreviation	
Ethernet modules Q series E71 (E71)	Abbreviation for Q series Ethernet interface modules QJ71E71, QJ71E71-B2. (Indicated as "E71" in the diagrams)	
Q series C24 (C24)	Abbreviation for Q series serial communication modules QJ71C24, QJ71C24-R2. (Indicated as "C24" in the diagrams)	
QC24	Generic term for AJ71QC24, AJ71QC24-R2, AJ71QC24-R4, A1SJ71QC24, A1SJ71QC24-R2.	
QC24N	Generic term for AJ71QC24N, AJ71QC24N-R2, AJ71QC24N-R4, A1SJ71QC24N, A1SJ71QC24N-R2.	
QC24(N)	Generic term for QC24, QC24N.	
QCPU	Q mode	Generic term for Q02CPU, Q02HCPU, Q06HCPU, Q12HCPU, Q25HCPU.
QCPU station	Abbreviation for the PLC with QCPU installed.	
QnACPU	Generic term for Q2ACPU, Q2ACPU-S1, Q2ASCPU, Q2ASCPU-S1, Q2ASHCPU, Q2ASHCPU-S1, Q3ACPU, Q4ACPU, Q4ARCPU.	
QnACPU station	Abbreviation for the PLC with QnACPU installed.	
Q/QnACPU	Generic term for QCPU, QnACPU.	
UC24 Computer link module	Generic term for AJ71UC24, A1SJ71UC24-R2, A1SJ71UC24-R4, A1SJ71UC24-PRF, A1SJ71C24-R2, A1SJ71C24-R4, A1SJ71C24-PRF, A2CCPUC24, A2CCPUC24-PRF. ＊ A series computer link modules.	
Serial communication module	Generic term for the module below.	
	QnA series	AJ71QC24, AJ71QC24-R2, AJ71QC24-R4, A1SJ71QC24, A1SJ71QC24-R2, AJ71QC24N, AJ71QC24N-R2, AJ71QC24N-R4, A1SJ71QC24N, A1SJ71QC24N-R2.
	Q series	QJ71C24, QJ71C24-R2

A - 20

(2) Other generic terms and abbreviations

This manual uses the following generic terms and abbreviations to explain the data-communication devices for the serial communication module. The names/model names are provided when it is necessary to explicitly identify the model being discussed.

Generic term/abbreviation	Description of generic term/abbreviation
ACT	Abbreviation for MX Component (SWnD5C-ACT-E). (n in the model name should be 0 or greater)
Buffer memory	Generic term for memory of the intelligent function modules/special function modules used for storing data sent to or received from the PLC CPU (setting values, monitor values, etc.)
Computer	Generic term for one of the external devices with which data can be sent/received using the MC protocol or the bidirectional protocol.
CSKP	Abbreviation for MX Links (SWnD5F-CSKP-E). (n in the model should be 3 or greater)
Data communication functions	Generic term for MC protocol, non procedure protocol, and bidirectional protocol.
GX Developer	Abbreviation for GX Developer (SWnD5C-GPPW-E). (n in the model should be 4 or greater)
I/F	Abbreviation for interface
Intelligent function module devices	Generic term for buffer memory of the intelligent function modules used for storing data sent to or received from the PLC CPU (setting values, monitor values, etc.)
Intelligent function modules	Generic term for the Q series PLC modules that are operated by commands from the PLC CPU (equivalent to the A series PLC special function modules). Examples: • CC-Link interface module • A/D and D/A conversion modules • Ethernet interface module • Serial communication module
MELSECNET/10	Abbreviation for MELSECNET/10 network system.
MELSECNET/H	Abbreviation for MELSECNET/H network system.
Opposite devices (external devices)	Generic term for computers, indicators, measuring instruments, ID modules, bar code readers, regulators, other serial communication modules, UC24, etc. that are connected to this serial communication module for data communication.
QSCU	Abbreviation for GX Configurator-SC (SW0D5C-QSCU-E). Initial settings for the module, monitoring and testing can be performed without using a sequence program and without considering I/O signals or buffer memory.
Reference Manual	Q Corresponding MELSEC Communication Protocol Reference Manual
RS-232 (interface)	Abbreviation for interface conforming to RS-232.
RS-422/485 (interface)	Abbreviation for interface conforming to RS-422 and RS-485.
Special function modules	Generic term for the A/QnA series PLC modules that are operated by commands from the PLC CPU (equivalent to the Q series PLC intelligent function modules). Examples: • CC-Link interface module • A/D and D/A conversion modules • High-speed counter module • Ethernet interface module • Computer link module and serial communication module
User's Manual (Application) or Application	Q Corresponding Serial Communication Module User's Manual (Application)
User's Manual (Basic) or Basic	Q Corresponding Serial Communication Module User's Manual (Basic)

A - 21

Definitions and Descriptions of Terminology

The following table lists the definitions and descriptions of terminology used in this manual and related manuals for the Q series serial communication modules.

Terms	Description
A compatible IC frame (Formats 1 to 4)	One of the message formats for the serial communication module for performing communication using the MC protocol and ASCII code data. This is the same message format as when communicating using the protocol for the A series computer link modules. Device memory read/write operations for the QCPU are allowed within the device range of the AnACPU. For details, see Chapter 5 of the Reference Manual.
Bidirectional protocol	A communication procedure for the serial communication modules and one of the data communication functions for communicating any data between the PLC CPU and an opposite device. Details are explained in Chapter 7.
Independent operation	A mode of interface operation to communicate data with external devices using a function specified in each communication protocol setting. Two interfaces of serial communication modules do not interact.
Linked operation	The operation mode of each of the two interfaces for a serial communication module that are connected to external devices and linked to one another in order to send/receive data to/from the external devices. The two interfaces communicate data using the identical data-communication function (MC protocol (identical format) or non procedure protocol) and the identical transmission specifications. (Linked operation using the bidirectional protocol is not allowed.)
MELSEC communication protocol (MC protocol)	A communication procedure for the Q series serial communication modules or the Ethernet interface modules, and a name of communication method for accessing to the PLC CPU from an opposite device. (This is called the MC protocol in this manual.) There are two communication methods; one uses ASCII code data and the other uses binary code data. Details are explained in the Reference Manual.
Message send function (Printer function)	This function registers character data (messages) to be sent to external devices (mainly printers) in the serial communication module as an user frame in advance, and sends the registered data for multiple user frames using the non procedure protocol (sent by an instruction from the PLC CPU).
Multidrop connection	A name of the connection when multiple external devices or other serial communication modules are connected in a 1:n or m:n mode using the serial communication module's RS-422/485 interface.
Non procedure protocol	An user's communication procedure and one of the data communication functions for communicating any data between the PLC CPU and an opposite device. Details are explained in Chapter 6.
QnA compatible 2C frame (Formats 1 to 4)	One of the message formats for the serial communication module for performing communication using the MC protocol and ASCII code data. This is the same message format as the communication frame using the protocol for the QnA series serial communication modules. • QnA compatible 2C frame (Formats 1 to 4): QnA simplified frame (Formats 1 to 4) Details are explained in Chapter 4 of the Reference Manual.
QnA compatible 3C frame (Formats 1 to 4) QnA compatible 4C frame (Formats 1 to 4)	One of the message formats for the serial communication module for performing communication using the MC protocol and ASCII code data. This is the same message format as the communication frame using the protocol for the QnA series serial communication modules. • QnA compatible 3C frame (Formats 1 to 4): QnA frame (Formats 1 to 4) • QnA compatible 4C frame (Formats 1 to 4): QnA extension frame (Formats 1 to 4) Details are explained in Chapter 3 of the Reference Manual.

Terms	Description
QnA compatible 4C frame (Format 5)	One of the message formats for the serial communication module for performing communication using the MC protocol and binary code data. This is the same message format as the communication frame using the protocol for the QnA series serial communication modules. • QnA compatible 4C frame (Format 5): QnA extension frame (Format 5) Details are explained in Chapter 3 of the Reference Manual.
User frame	Data name when the fixed format portion of messages to be sent or received between a serial communication module and an opposite device is registered in the module and used for sending and receiving data with the functions listed below. (The contents of an user frame data should conform to the specifications of the opposite device). The data array of the head and tail sections of a message (transmission control code, C24 station number, sum check, fixed data, etc.) to be sent and received is registered in the serial communication module before use. • MC protocol on-demand function. • Data communication function using the non procedure protocol. Details are explained in Chapter 9 of the User's Manual (Applications).

Product Configuration

The following lists the product configuration of the Q series serial communication modules.

Model	Item name	Quantity
QJ71C24	QJ71C24 serial communication module	1
	Terminal resistor 330Ω 1/4 W (for RS-422 communication)	2
	Terminal resistor 110Ω 1/2 W (for RS-485 communication)	2
QJ71C24-R2	QJ71C24-R2 serial communication module	1
SW0D5C-QSCU-E	SW0D5C-QSCU-E serial communication module setting·monitor tool	1
	SW0D5F-QSCKEY-E license key FD	1

A - 23

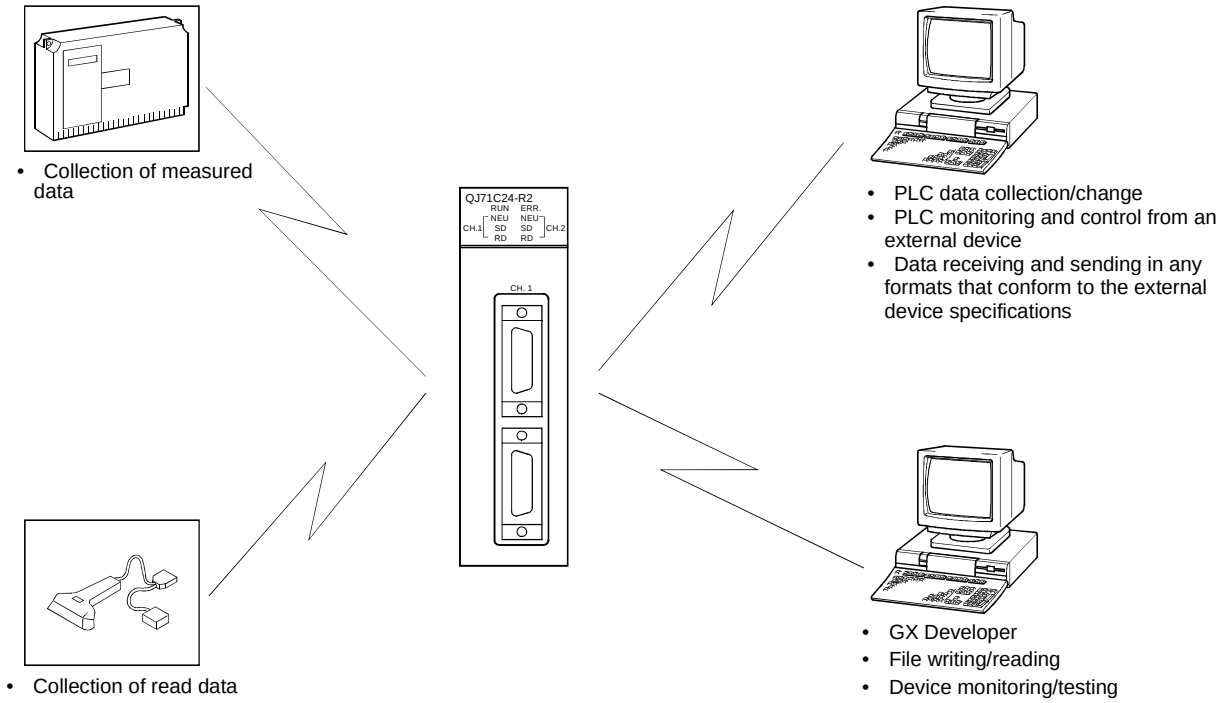
1 OVERVIEW

This manual describes the specifications for the QJ71C24 (-R2) serial communication module (hereinafter referred to as "Q series C24"), as well as the procedures prior to starting the operation, maintenance, inspection, data communication methods for use with external devices and troubleshooting.

1.1 Overview of the Serial Communication Module

The Q series C24 is a module that connects the Q series PLC CPU and an external device using an RS-232 or RS-422/485 line for serial communication, in order to achieve the data communication described below.
By using a modem/terminal adapter, a public line (analog/digital) can be used for data communication with a remote location.

- PLC data collection/change from the external devices
  (See the MELSEC Communication Protocol Reference Manual.)
- PLC monitoring and control from the external devices (See Chapter 2 of the User's Manual (Application).)
- Data receiving and sending in any formats that conform to the external device specifications (See (2) and (3) of Section 1.2.)
- Collection of measured data from a measuring device (See (2) of Section 1.2.)
- Operation of a PLC CPU that is connected to a personal computer (hereinafter abbreviated as PC) installed with GX Developer (SW4D5C-GPPW-E or later, hereinafter abbreviated as GX Developer). (See the GX Developer Manual.)



✻ Being a convenient means of connection among different devices (PCs, display devices, printers, etc.), the serial communication line is the most widely used medium on the market today.

1 - 1

1.2 Features of the Serial Communication Module

The following describes the features of the Q series C24.

(1) Data communication based on the MELSEC communication protocol (hereinafter referred to as the MC protocol)
(Details are explained in the MELSEC Communication Protocol Reference Manual.)

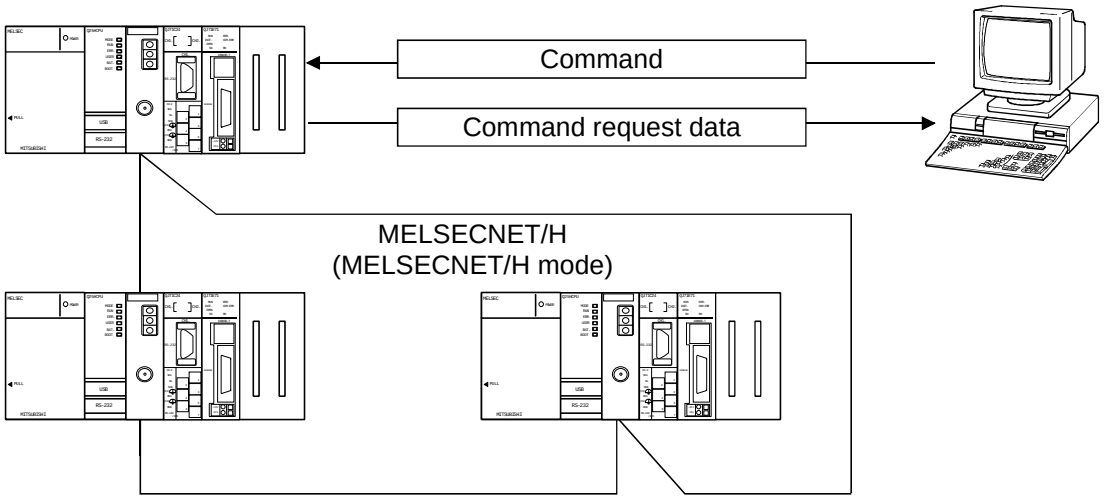
(a) External devices can read/write the PLC device data and sequence programs, and can monitor PLC equipment status.
With the exception of the on-demand function described below, the PLC does not require a sequence program because the PLC sends and receives data based solely on commands from external devices.

(b) Using the on-demand function, data can be sent from the PLC CPU to the external devices in each frame format of the MC protocol.

(c) Data communication can be performed using a program at the external device side that has been created for communicating data with conventional A/QnA series computer link module/serial communication modules.

(d) If the external device is a PC running one of the basic operation systems below, it is possible to create a communication program for the external device without considering the detailed MC protocol (transmission/reception procedures) using one of the following separately sold communication support tools.
(Supported basic operation systems)
- Microsoft® Windows® 95 operating system
- Microsoft® Windows® 98 operating system
- Microsoft® Windows NT® Workstation4.0 operating system

(Separately sold communication support tools)
- MX Component (SW0D5C-ACT-E, hereinafter abbreviated as ACT)
- MX Links (SW3D5F-CSKP-E and later, hereinafter abbreviated as CSKP)



* In the MELSECNET/10 mode, other stations (including the A/QnA series PLC CPUs) can be accessed during data link operation.
* The MC protocol is equivalent to the communication function using a dedicated protocol that is supported by the A/QnA series computer link module/serial communication modules.

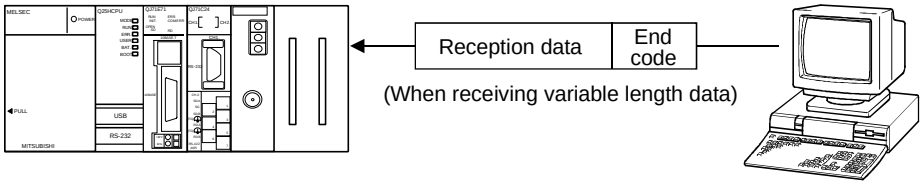
(2) Data communication using the non procedure protocol

(Details are explained in Chapter 6 and the User's Manual (Application).)

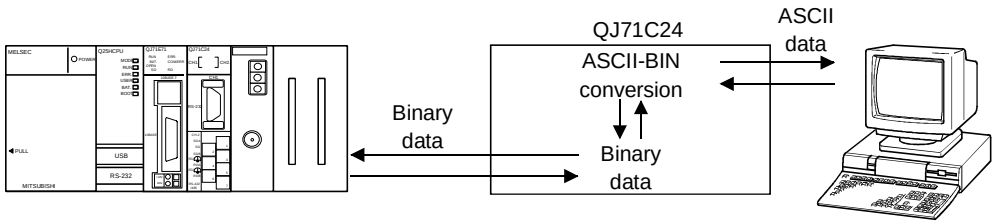
(a) Data can be transferred in any message formats that conform to the specifications of external devices (measuring devices, PCs, etc.).

(b) Fixed or variable length messages can be received in accordance with the external device specifications.

- How to receive the variable length data
  The external device sends data by adding at the end of the message the end-code data (CR+LF or any one-byte data) that is set for the Q series C24.
- How to receive the fixed length data
  The external device sends the amount of data equivalent to the size of the end data that is set for the Q series C24.



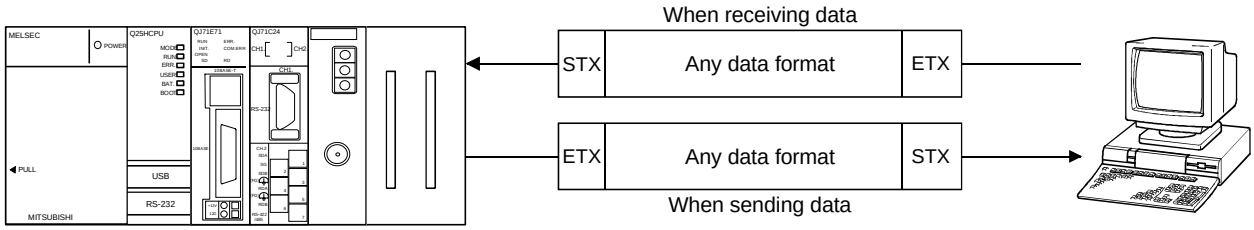
(c) ASCII code data can be used for communication using the ASCII-BIN conversion function.



(d) It is necessary to create a sequence program for communication control that conforms to the external device.

(e) Communication can be performed using an user frame by registering the fixed format portion of the head and tail sections of a message as an user frame.

- When sending data, the Q series C24 adds an user frame to any data specified by the user.
- When receiving data, the Q series C24 transfers any data excluding the user frame to the PLC CPU.



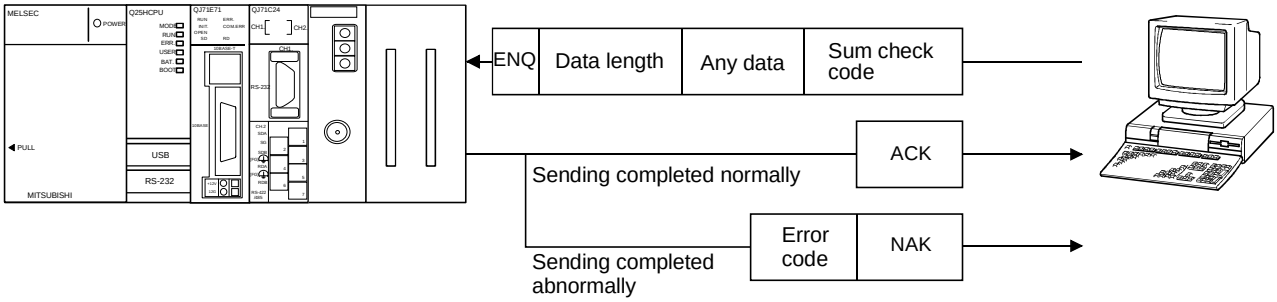
(f) It is possible to clear the current reception data without interrupting the transmission processing by using the dedicated instruction "CSET."

(3) Data communication using the bidirectional protocol

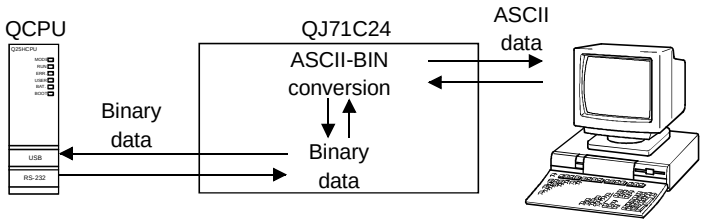
(Details are explained in Chapter 7 and the User's Manual (Application).)

(a) In communication between PLC CPUs and communication with an external device for which transmission/receive control programming is allowed, data communication is performed in a sequence of "data transmission and response receipt".

(b) Error check of received data can be performed using the sum-check code, while the occurrence of a reception error at an external device can be checked via an ACK/NAK response.



(c) ASCII code data can be used for communication using the ASCII-BIN conversion function.



(4) Monitoring the PLC CPU

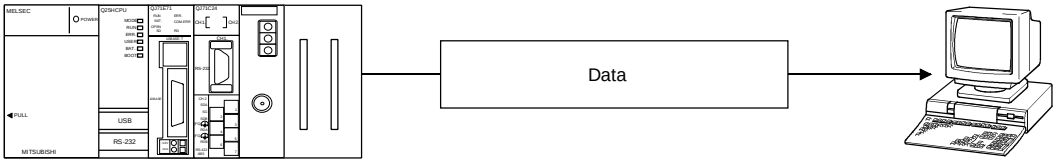
(Details are explained in the User's Manual (Application).)

(a) The self-station's PLC CPU can be monitored at time intervals set by the user without using a sequence program.

1) The following monitoring information can be sent/notified as the result of monitoring the PLC CPU.
   - Transmission of information on devices and the PLC CPU status to be monitored. (It is also possible to send the monitoring information through combined use of the modem function.)
   - Notification of a notification message (string data) registered as the connection data of the modem function, through combined use of the modem function.

2) The user can select either one of the following timing choices at which to send the PLC CPU monitoring result to the external device.
   - Send/notify every time the PLC CPU is monitored (periodic transmission).
   - Send/notify when the information read from the PLC CPU matches the conditions set by the user (conditional transmission).

(b) The PLC CPU monitoring function can be used in communication using the MC or non procedure protocol.



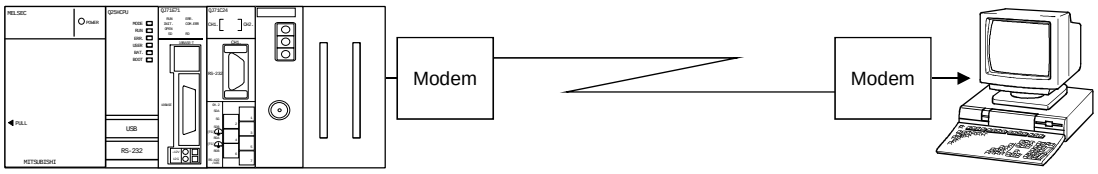
(5) Remote communications using the modem function

(Details are explained in the User's Manual (Application).)

(a) Data communication can be performed with a remotely located external device.

(b) Modem initialization and line connection/disconnection can be performed.

(c) Data communication can be performed using the MC, non procedure or bidirectional protocol.



(6) Initial settings and communication settings without using a sequence program

Various initial settings can be performed using the GX Congifurator-SC (SW0D5C-QSCU-E, hereinafter abbreviated as QSCU).

(7) Connecting the GX Developer and the GOT

(a) Connecting the GX Developer (Details are explained in the GX Developer Operating Manual.)

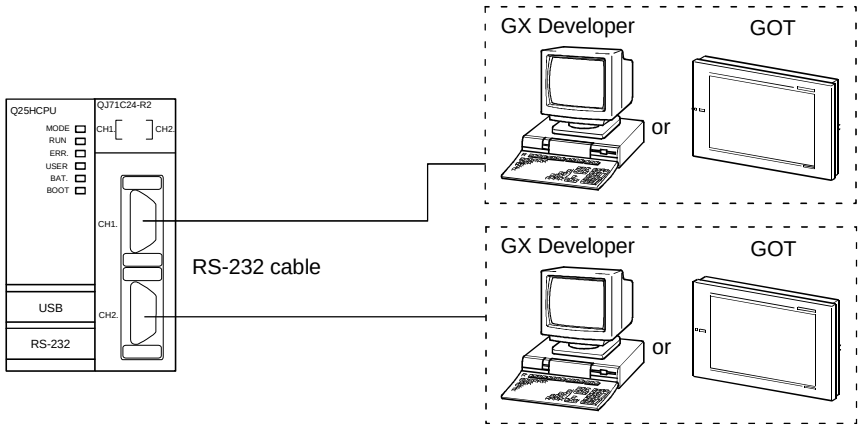
- By connecting a PC installed with a GX Developer to the interface of the Q series C24 at the same time, operations such as programming, monitoring and testing for the PLC CPU can be performed.
- By connecting multiple PCs installed with GX Developers to the PLC CPU or Q-series C24 at the same time, operations such as programming and monitoring can be performed simultaneously by multiple operators. Operating the GX Developers using these simultaneous connections can improve program performance.
- Operations can be performed from a GX Developer by setting the communication protocol of the Q series C24 interface to which a PC is connected to "0" with the switch setting using the GX Developer.

(b) Connecting the GOT (Details are explained in the GOT User's Manual (Connection).)

- By connecting a GOT (graphic operation terminal) to the interface for the Q series C24 operations such as monitoring the PLC CPU can be performed.
- Operations such as monitoring the PLC CPU can be performed by setting the communication protocol of the Q series C24 interface to which a GOT is connected to "0" with the switch setting using a GX Developer.

(c) Simultaneous connection of GX Developer and GOT

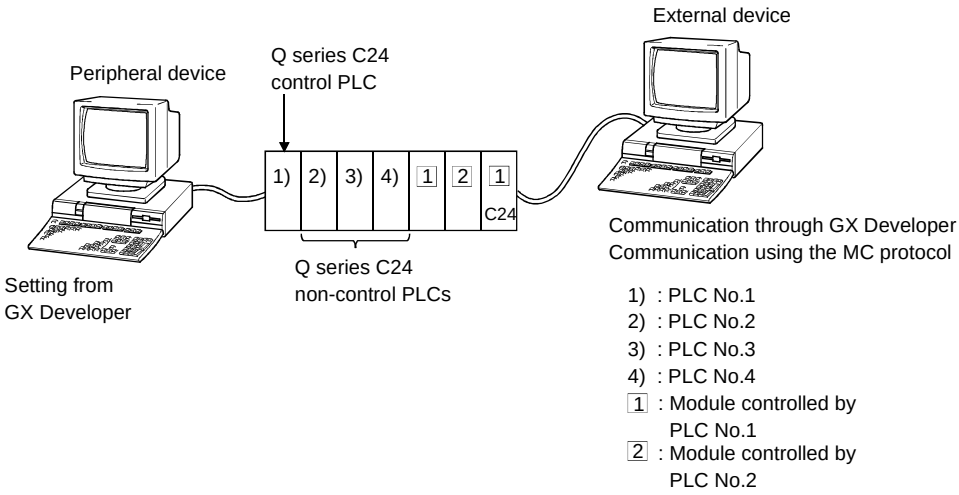
- It is possible to connect a PC with GX Developer and the GOT to two interfaces of the Q series C24 at the same time. It is thus possible for more than one user to perform programming, monitoring, etc. simultaneously.
- When the GOT and the PC with GX Developer are connected at the same time, the two interfaces of the Q series C24 cannot perform an interlock operation.



(8) Functions supporting multiple PLC systems (Details are explained in the Reference Manual.)

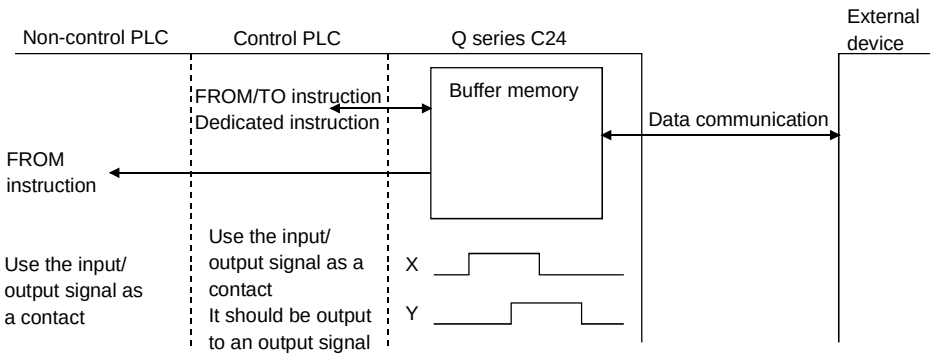
(a) When accessing QCPUs in a multiple PLC system using the MC protocol or through GX Developer (SW6D5C-GPPW-E), it is possible to perform data communication such as reading/writing device data by specifying the QCPU to be accessed.

- When using the Q series C24 in a multiple PLC system, a QCPU controlling the Q series C24 (hereinafter referred to as the control PLC) should be specified using GX Developer (SW6D5C-GPPW-E).
  It is also possible to mount a Q series C24 of function version A in a multiple PLC system and access to the only control PLC (PLC No.1).



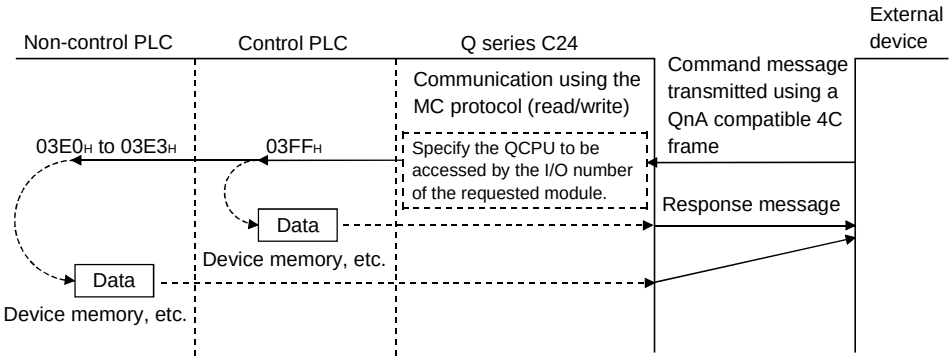
(b) When a Q series C24 CPU of function version B is used in a multiple PLC system, the following forms of data communication can be performed with the Q series C24.

1) It is possible to perform data communication using the non procedure/bidirectional protocols from the control PLC
2) It is possible to read the buffer memory from non-control PLCs. Input/output signals can be used as contacts.



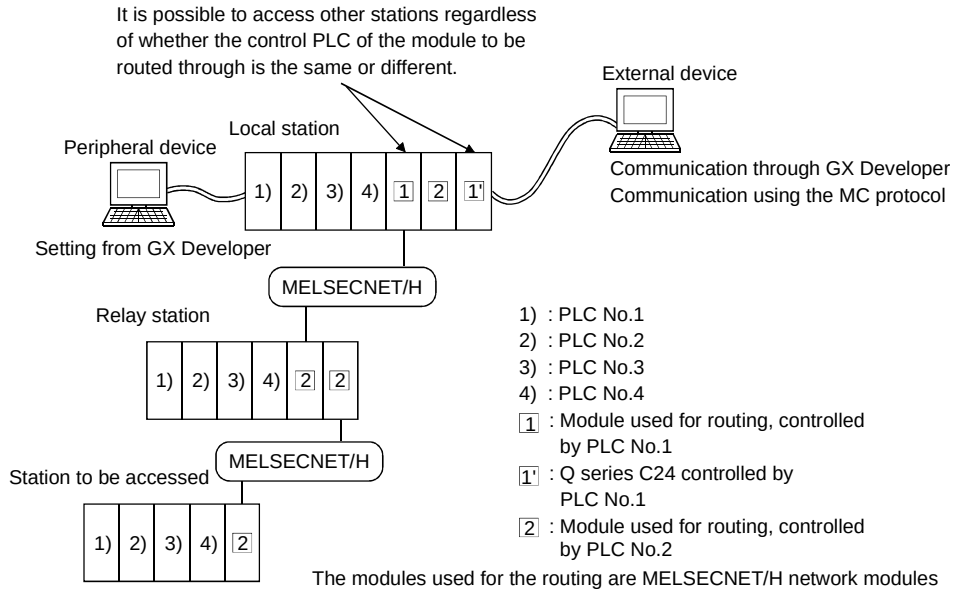
POINT
In a multiple PLC system mounted the Q series C24, it is only the control PLC of the Q series C24 that can use the functions of the Q series C24.

3) It is possible to access the control PLC and non-control PLCs using the MC protocol and through GX Developer (SW6D5C-GPPW-E) from the external device.
In addition, data communication with the control PLC of the Q series C24 can be performed using the non procedure/bidirectional protocol.



If the MC protocol is used to access other stations, it is possible to access the control PLC and non-control PLCs of the station to be accessed even if the relay station and the accessed station are multiple PLC systems.

(Example)



* The QnA compatible 4C frame should be performed for access to non-control PLCs when communicating using the MC protocol.
However, the available functions differ depending on the QCPU to be accessed (whether it is a control PLC or a non-control PLC).
See the Reference Manual for the available functions and accessible range.

* A module used for routing can access the following modules when accessing other stations:
  - MELSECNET/H, MELSECNET/10 network module
  - Q series C24 • Ethernet interface module

* If there is a module of function version A among the modules for routing, it is possible to access the control PLC of that particular module only. In addition, it is possible to access other stations via a module controlled by the same control PLC.

(9) Remote password check function

(Details are explained in the User's Manual (Application) and the Reference Manual.)

(a) The remote password check function of the Q series C24 prevents users at a remote location to access QCPUs illegally using the modem function of the Q series C24.

(The remote password is checked in the following forms of data communication)

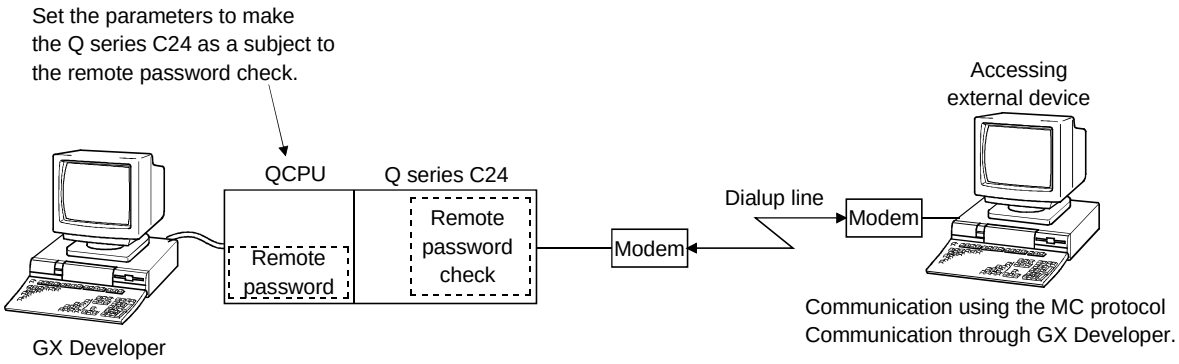
- Communication using the MC protocol
  (The remote password check is not carried out in data communication using the non procedure/bidirectional protocols.)
- Access to the PLC through GX Developer (SW6D5C-GPPW-E)

* The remote password function is one of the QCPU functions and used for preventing illegal access to the QCPU by other users.
  Use GX Developer (SW6D5C-GPPW-E) to set a remote password for the QCPU in order to activate the remote password function of the QCPU.

(b) If the Q series C24 is specified in the parameters of a QCPU as being subject to the remote password check, the remote password can be unlocked (canceled) using either one of the methods below, to allow data communication from the external device. It is necessary to connect a line to the modem first.

- When communicating using the MC protocol
  Use the dedicated command for communication using the MC protocol to unlock the remote password from the external device.
- When accessing the PLC through GX Developer (SW6D5C-GPPW-E)
  Unlock the remote password using GX Developer (SW6D5C-GPPW-E) at the start of online operation.

The remote password is automatically locked by disconnecting the line to the modem.



1.3 About Added/Changed Functions in Function Version B

The table below lists the functions that have been added or changed in the Q series C24 of function version B.

Function	Outline of function	Reference section
Simultaneous connection of GX Developer and GOT	This function allows access to the PLC from a PC with GX Developer and a GOT connected to two different interfaces of the Q series C24 at the same time.	Section 1.2 of User's Manual (Basic)
Clearing reception data by a dedicated instruction	This function allows clearing reception data using the CSET instruction during data communication using the non procedure protocol. It is possible to clear the data even when data is being transmitted.	Chapter 6, Section 9.8 of User's Manual (Basic)
Transmission of the PLC CPU monitoring information through combined use of the modem function	When the PLC CPU monitoring function is active, this function sends the monitoring information of the PLC CPU to the external device through the modem.	Chapter 2 of User's Manual (Application)
Addition of changeable data to the user frame	The following codes can be registered as changeable data for user frames for data communication: • Horizontal parity code • Sum check code of two's-complement number	Chapter 9 of User's Manual (Application)
Adding a reception function through the use of user frames	This function allows reception of a message consisting of the head frame and any data field when receiving data by specifying the head frame. The data length of the data field can be specified freely for each combination of user frames for reception set by the user. (Receiving 1 byte providing ACK/NAK only is also possible by setting the data length of the data field to "0.")	Chapter 11 of User's Manual (Application)
Multiple specification of transparent codes for transmission	This function allows specification of a maximum of 10 types of transparent codes for transmission per interface when sending data using one of the following protocols: • Non procedure protocol • Bidirectional protocol	Chapter 12 of User's Manual (Application)
Remote password check	This function allows data communication after the external device completes the unlock processing of the remote password set at a QCPU. It is executed when the QCPU is accessed from a remote location using the modem function of the Q series C24 in the following forms of data communication: • Communication using the MC protocol • Communication using GX Developer (SW6D5C-GPPW-E)	Chapter 3 of User's Manual Section 3.18 of Reference Manual
Support for multiple PLC system	This function allows access to the control/non-control PLCs specified by the user when performing the following forms of data communication with a multiple PLC system: • Communication using the MC protocol • QCPU access from GX Developer (SW6D5C-GPPW-E)	Section 2.10 of Reference Manual
Data transmission/reception at low speed	This function allows data communication with an external device at a transmission speed of 50 bps.	Chapter 4 of User's Manual (Basic)

POINT

(1) See Appendix 1.1 for a comparison of functions by function version.
(2) See Section 2.6 for how to check the function version.

2 SYSTEM CONFIGURATION AND AVAILABLE FUNCTIONS

This Chapter describes the system configuration and available functions.

2.1 Applicable Systems

The following describes applicable systems.

(1) Applicable modules and number of modules that can be mounted

The following table lists the CPU module and remote I/O stations that the Q series C24 can be mounted and the number of modules which can be mounted.

Applicable module		Number of modules that can be mounted	Remarks
CPU module	Q02CPU Q02HCPU Q06HCPU Q12HCPU Q25HCPU	Maximum 64	Can only be mounted in Q mode.
Remote I/O station	QJ72LP25-25 QJ72BR15		MELSECNET/H remote I/O station

(2) The base module to which the Q series C24 can be mounted

The Q series C24 can be mounted into any I/O slot (*1) of the base module.

*1 Limited to within the range of I/O points for the CPU module and remote I/O station

(3) Applicable software packages

The following table lists the software/setting & monitor tool available for the Q series C24.

(a) Software/setting & monitor tool for the PLC

Item name	Model	Remarks
GX Developer	SWnD5C-GPPW-E (-V)	MELSEC PLC programming software The "n" in the model name is 4 or greater
GX Configurator-SC	SWnD5C-QSCU-E	Q series serial communication module setting/monitor tool SWnD5C-GPPW-E is required

(b) Communication support tools for external device

Item name	Model	Remarks
MX Component	SWnD5C-ACT-E	ActiveX library for communication The "n" in the model name is 0 or greater.
MX Links	SWnD5C-CSKP-E	DLL library for communication The "n" in the model name is 3 or greater.

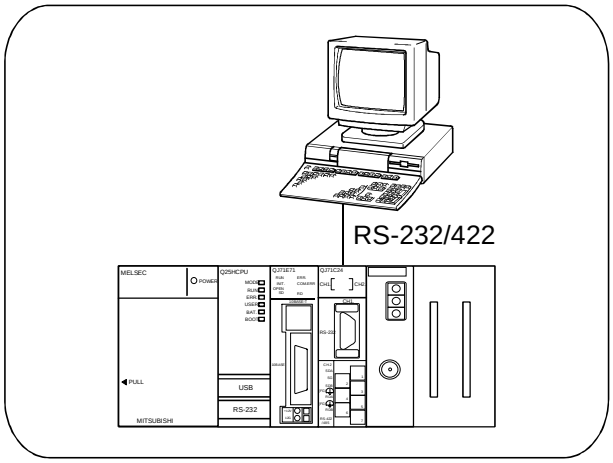
2.2 Combinations of PLC CPU and External Device, and Available Functions

The following describes the system configurations and available functions when using the Q series C24.

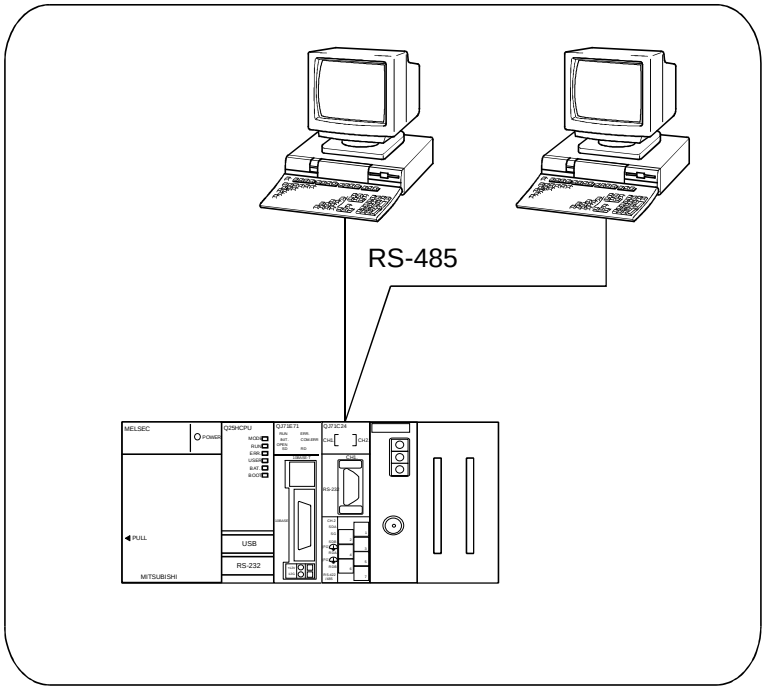
(1) System configurations

System configurations (combinations of PLC CPU and external device) for data communication are shown below.

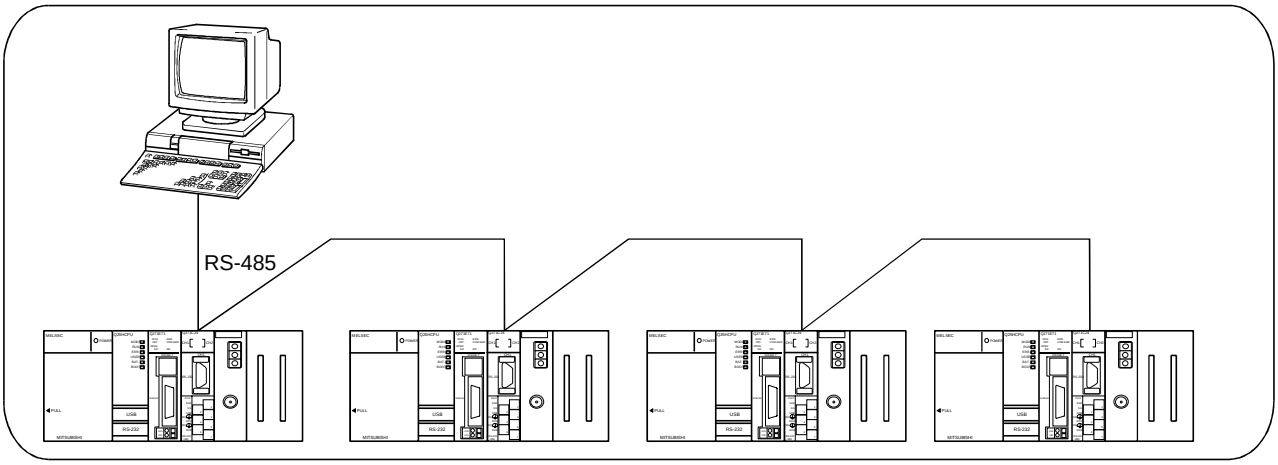
(a) For 1:1 system configuration (external device: Q series C24)

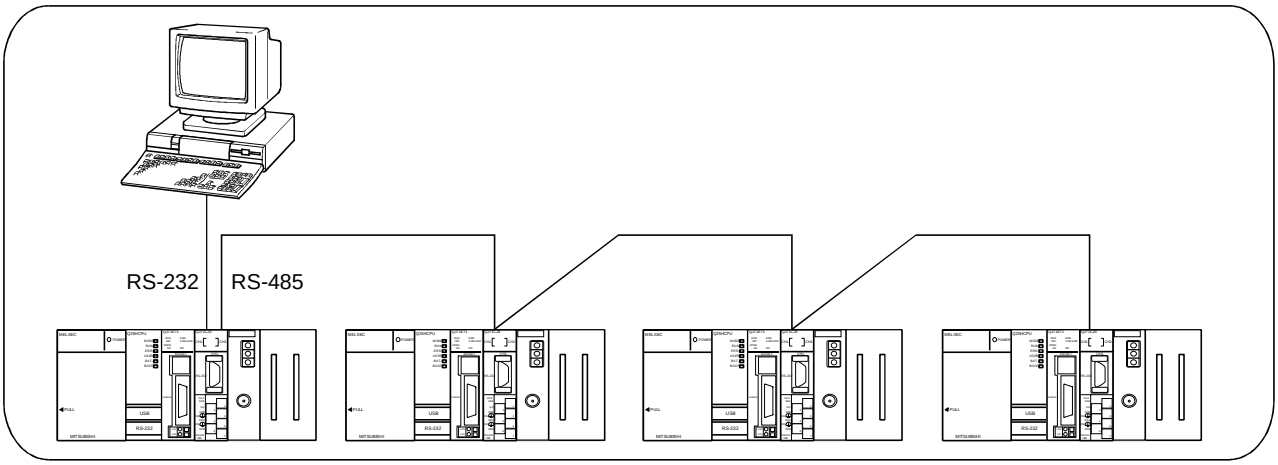


(b) For n:1 system configuration (external device: Q series C24)

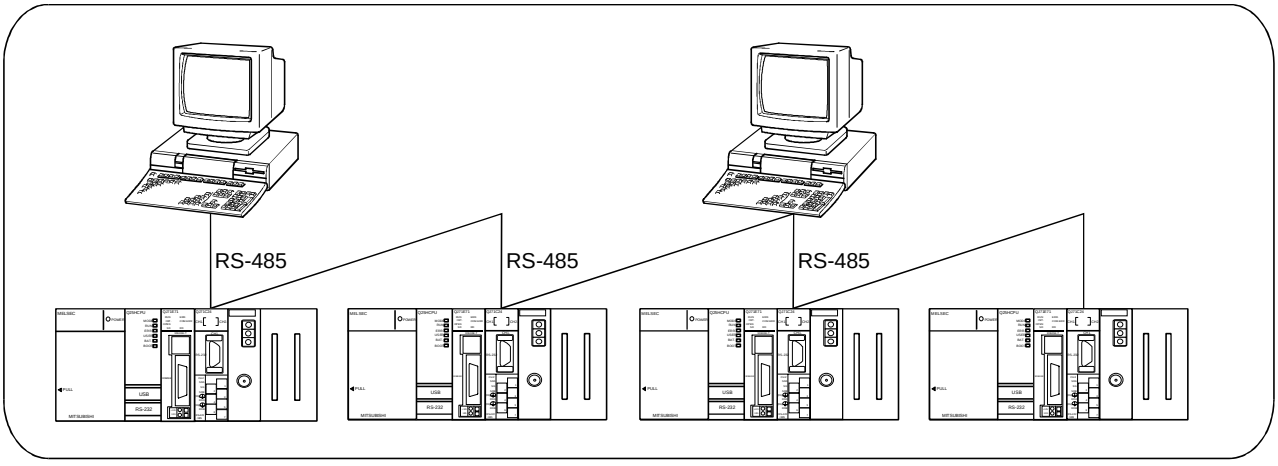


(c) For 1:n system configuration (external device: Q series C24)





(d) For m:n system configuration (external device: Q series C24)



(2) Correspondence between the data communication functions and system configurations

The following shows system configurations that can use the data communication functions of the Q series C24.

The manual names shown in the reference section column in the table below are as follows:

- Application
  Q Corresponding Serial Communication Module User's Manual (Application)
- Reference
  Q Corresponding MELSEC Communication Protocol Reference Manual

(a) Communication using the MC protocol (○ : Available, × : Not available)

Functions of the Q series C24	System configuration				Reference section	
	1 : 1	n : 1	1 : n	m : n		
PLC CPU device memory read/write	○	○	○	○	Reference	Section 3.3
Intelligent function module buffer memory read/write	○	○	○	○		Section 3.5
Sequence program read/write	○	○	○	○		Section 3.8
PLC CPU status control (remote RUN, STOP, etc.)	○	○	○	○		Section 3.6
On-demand function	○	×	×	×		Section 3.11
					Application	Chapter 10
Global function	○	○	○	○	Reference	Section 3.10
Accessing the PLC of other stations in the MELSECNET/H, MELSECNET/10	○	○	○	○		Section 2.7
PLC CPU monitoring function	○	×	×	×	Application	Chapter 2

(b) Communication using the non procedure protocol

(○ : Available, × : Not available)

Functions of the Q series C24	System configuration				Reference section	
	1 : 1	n : 1	1 : n	m : n		
Data transmission/receiving in arbitrary format	○	○	○	○	This manual	Chapter 6
Data transmission/receiving with user frames	○	○	○	○	Application	Chapter 11
PLC CPU monitoring function	○	×	×	×		Chapter 2
Reading received data using interrupt programs	○	○	○	○		Chapter 4
Sending/receiving ASCII data using ASCII-BIN conversion	○	○	○	○		Chapter 13

(c) Communication using the bidirectional protocol

(○ : Available , × : Not available)

Functions of the Q series C24	System configuration				Reference section	
	1 : 1	n : 1	1 : n	m : n		
Data transmission/receiving	○	×	×	×	This manual	Chapter 7
Reading received data using interrupt programs	○	×	×	×	Application	Chapter 4
Sending/receiving ASCII data using ASCII-BIN conversion	○	×	×	×		Chapter 13

✻ In general, if data communication is performed using a system configuration of other than 1:1 connection mode, the following points should be well noted.

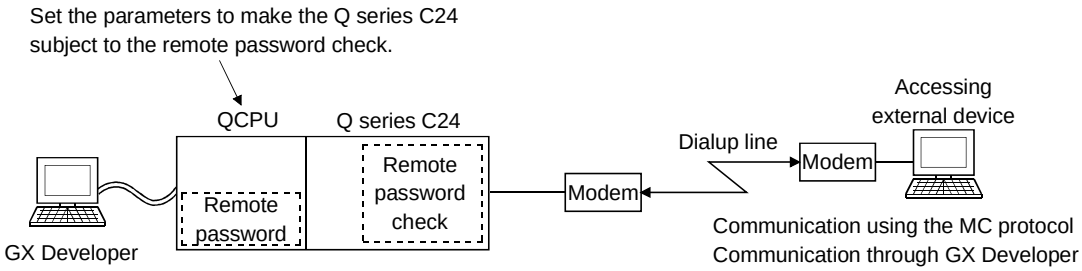
- Avoid simultaneous transmission.
- Discard data received other than that addressed to the local station.

2.3 When Using the Remote Password Function of the QCPU

This section explains how to use the remote password function of the QCPU.

(1) Use the following Q series C24 and QSCU to QCPU remote password to activate the remote password check function of the Q series C24.
- Q series C24 of function version B
- QSCU software of version C (20C) or later

(2) Forms of data communication in which a remote password is checked:
- Communication using the MC protocol
  ✻ The remote password check is not carried out in data communication using the non procedure/bidirectional protocols.
- Access to the PLC through GX Developer (SW6D5C-GPPW-E)



POINT

(1) It is possible to use the remote password function of the QCPU by using any of the following QCPUs (in Q mode).
- QCPU of function version A (Q mode)
- QCPU (in Q mode) that first 5 digits of the serial No. 02092 ✻✻✻✻✻✻✻✻✻✻ are 02092 or later

See Section 2.6 for how to check the function version and serial No.

(2) Refer to the following manuals when using the remote password function of the QCPU.
- Section 1.2 (9) of this manual
- Section 3.3.3 of the User's Manual (Application)

2.4 When Using the Q Series C24 at a Remote I/O Station

This section describes the overview or reference section for each of the purposes that the Q series C24 is used for at a remote I/O station in MELSECNET/H network.

POINT

(1) It is not necessary to read this section if the Q series C24 is mounted at the QCPU station.

(2) The system for the MELSECNET/H (remote I/O network) can be configured by using any of the following QCPUs (in Q mode).
- QCPU of function version A (Q mode)
- QCPU (in Q mode) that first 5 digits of the serial No. 02092 ＊＊＊＊＊＊＊＊＊＊ are 02092 or later

See Section 2.6 for how to check the function version and serial No.

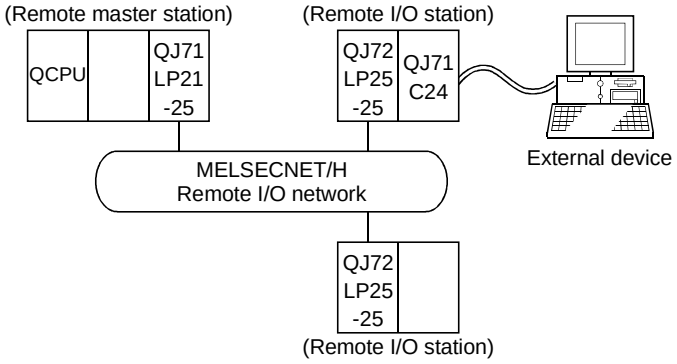
(3) Refer to the following manual together with this section when using the Q series C24 at a remote I/O station in MELSECNET/H network.
Q Corresponding MELSECNET/H Network System Reference Manual (Remote I/O Net)

(1) Remote I/O stations on which the Q series C24 can be mounted

See Section 2.1 for a list of the remote I/O stations on which the Q series C24 can be mounted.

(2) System configuration when using the Q series C24 at a remote I/O station

(Example)



(3) Available functions

The following functions are available when the Q series C24 is mounted on a remote I/O station.

* See Appendix 1.1 for a list of the Q series C24 functions available for each function version.

Function		Function available when mounted at a remote I/O station	Remarks
Communication using the MC protocol (*1)		○	See Reference Manual
Communication using the non procedure protocol		×	—
Communication using the bidirectional protocol		×	
Communication using the dedicated instructions		×	
Communication via public line, etc. (modem function)		×	
	Remote password check	×	
Transmission control	DC code control (including Xon/Xoff control)	○	
	DTR/DSR (ER/DR) control	○	
Communication protocol switching		×	
Independent/linked operation of each interface		○	
Initial setting and monitoring/testing the setting values by the utility package		○	
Connecting GX Developer and GOT at the same time		○	
Supporting multiple PLC system		—	A remote I/O station supports a single CPU system
	Communication with non-control PLCs using the MC protocol		
	Setting multiple PLCs using GX Developer		
Data transmission/reception at low speed (transmission speed: 50 bps)		○	—

○ : Available × : Not available

*1 The following functions are available when communicating with the MELSECNET/H remote I/O station using the MC protocol.

Available function	Function
Device memory read/write	Batch read and batch write
	Random read, test (random write)
	Monitor data registration, monitoring
	Batch read of multiple blocks, batch write of multiple blocks
Buffer memory read/write	Reading/writing from/to the buffer memory of the Q series C24
Reading/writing buffer memory of an intelligent function module	Reading/writing from/to the buffer memory of the specified intelligent function module

The following devices of a remote I/O station can be accessed by the device memory read/write function. Note that the accessible devices and the ranges vary depending on the type of frames used for the data communication.
See the Reference Manual for a detailed explanation.

Device name	Device symbol	Device name	Device symbol
Special relay	SM	Link relay	B
Special register	SD	Data register	D
Input relay	X	Link register	W
Output relay	Y	Link special relay	SB
Internal relay	M	Link special register	SW

REMARK

It is only possible to read/write from/to the buffer memory of an intelligent function module for the MELSECNET/10 remote I/O station compatible with the QnA/A series.

(4) Setting from GX Developer (SW6D5C-GPPW-E)

The following parameters should be set through GX Developer (SW6D5C-GPPW-E) in order to use the Q series C24 mounted to a remote I/O station.
Each of setting is the same way as when setting the parameters for the Q series C24 mounted to a QCPU station: see Section 4.5 and after.
See the operating manual for DX Developer for how to display each setting screen.
(Parameter setting items for the Q series C24 mounted to a remote I/O station)

Parameter setting item	Setting	Remarks
I/O Assignment	Set the module mounting information	See Section 4.5.1
Switch setting for I/O and intelligent function module	Set the transmission specification and the communication protocol for communication with the external device	See Section 4.5.2

POINT

(1) Connect GX Developer (SW6D5C-GPPW-E) to a remote I/O station and set the parameters.
(2) Reset the remote I/O station after changing the setting.

(5) When monitoring/setting with QSCU

(a) Use QSCU software of version D (30D) when using the Q series C24 at a remote I/O station in the MELSECNET/H network.
- Add-in to the GX Developer (SW6D5C-GPPW-E)
- QSCU software of version C (20C) or earlier cannot be used when using the Q series C24 at a remote I/O station in the MELSECNET/H network.

(b) About the automatic refresh setting
1) When reading/writing data created by the automatic refresh setting using PLC, the read/write operation should be performed by GX Developer. It cannot be performed from QSCU.
2) The devices used for the automatic refresh setting must be of the types M, B, D, or W.

POINT

(1) QSCU should be connected to a remote I/O station before the monitoring/setting.
(2) The remote I/O station should be reset after changing the setting.

2.5 When Using the Q Series C24 under the Multiple PLC System with Several QCPUs (Function Version B)

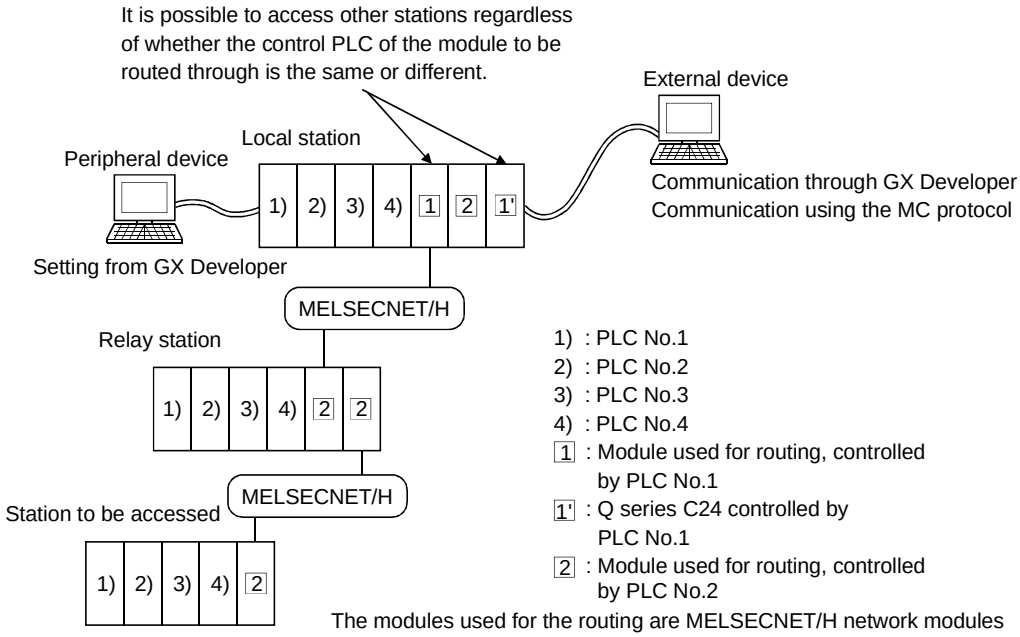
This section explains how to access non-control PLCs when using the Q series C24 under the multiple PLC system.
See Section 2.1 for other than below.

(1) The following Q series C24 and QSCU should be used when accessing non-control PLCs of the Q series C24 from a device connected to the Q series C24, using the functions shown in (2) below.
- Q series C24 of function version B
- QSCU software of version C (20C) or later

∗ If QSCU software of version B (10B) or earlier is used, it is possible to perform monitoring/setting within the function range of the Q series C24 of function version A.

(2) Forms of data communication in which the external device can access a non-control PLC.
- When the external device uses communication functions to access a non-control PLC using the MC protocol
- When accessing a non-control PLC through GX Developer (SW6D5C-GPPW-E)

(3) If the other stations to be accessed belong to the multiple PLC system, the modules used for routing and QCPUs at the local station, all the relay stations, and the accessed station should be modules of function version B. This has to hold in all cases of accessing the non-control PLC of the module used for routing at the accessed station.



∗1 When accessing other stations, a module used for routing can access the following modules:
- MELSECNET/H, MELSECNET/10 network modules
- Q series C24
- Ethernet interface modules

POINT

(1) A multiple PLC system can be built by using function version B of QCPUs (Q mode). See Section 2.6 for how to check function version.

(2) Refer to the QCPU (Q mode) User's Manual (Function Explanation/Program Fundamentals) before using the Q series C24 under the multiple PLC system.

2.6 Checking the Function Version, Serial No., and Software Version

This section explains how to check the QSCU software version, and the function version and serial No. of related products that can use the functions added by the improvement of the Q series C24.

(1) Correspondence of related products for use additional functions of Q series C24

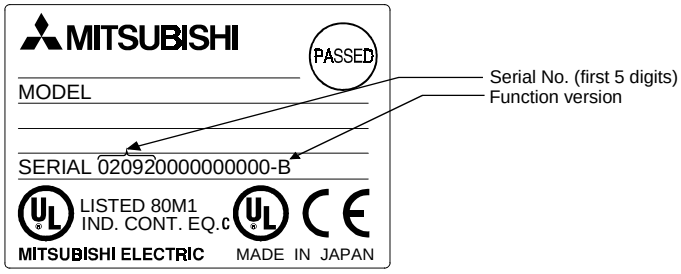
Additional function	Version of the related product		
	CPU module	Q series C24	QSCU
Simultaneous connection of GX Developer and GOT	—	Function version B	S/W version 20C
Clearing reception data by a dedicated instruction			
Transmission of the PLC CPU monitoring information through combined use of the modem function			
Addition of changeable data to the user frame			
Reception by user frame (reception according to format-1)			
Multiple specification of transparent codes for transmission			
Remote password check	Function version A, product that first 5 digits of the serial no. 02092 ∗ ∗ ∗ ∗ ∗ ∗ ∗ ∗ ∗ ∗ are 02092 or later		
Support for multiple PLC system	Function version B		
Data transmission/ reception at low speed (50 bps)	—		
MELSECNET/H remote mounted on I/O station	Function version A, product that first 5 digits of the serial no. 02092 ∗ ∗ ∗ ∗ ∗ ∗ ∗ ∗ ∗ ∗ are 02092 or later		S/W version 30D

—: Shows that there are no restrictions as to the serial No. or version of the related corresponding product when using additional functions of the Q series C24.

(2) Checking the version and serial No. of Q series PLC functions

(a) Using the rated plate on the side of the module to check

The serial No. and function version of the corresponding module is shown in the SERIAL column of the rated plate.



(b) Using the GX Developer to check

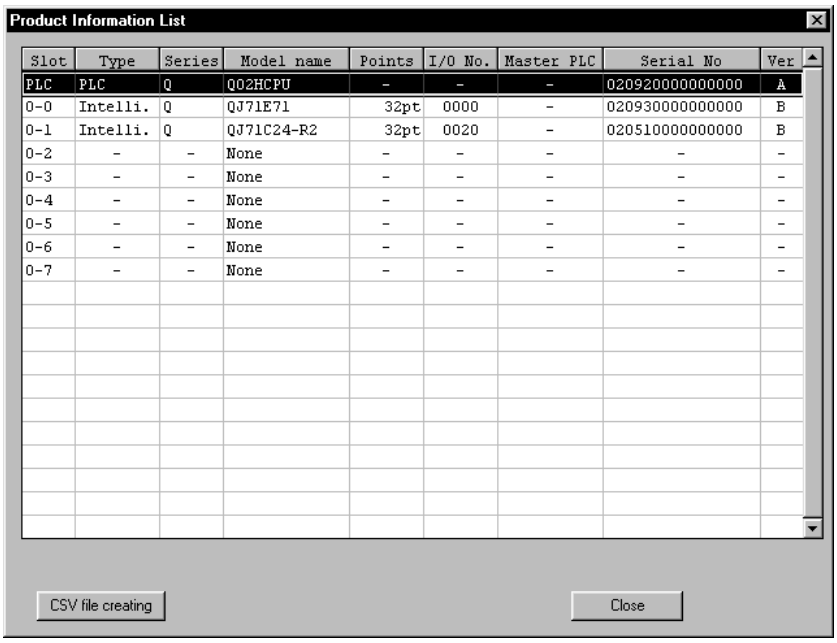
The method of checking the serial No. and function version of the corresponding module with the GX Developer using SW6D5C-GPPW-E is shown.

The serial No. and function version are displayed on the GX Developer "Product Information List" or "Module's Detailed Information" screen.

The method of checking the serial No. and function version on the "Product Information List" screen is shown below. (See Section 10.1.1 for details about the "Module's Detailed Information" screen.)

[Start Procedure]

"Diagnostics" → "System monitor" → "Product Inf. List"



[Serial No., Ver.]

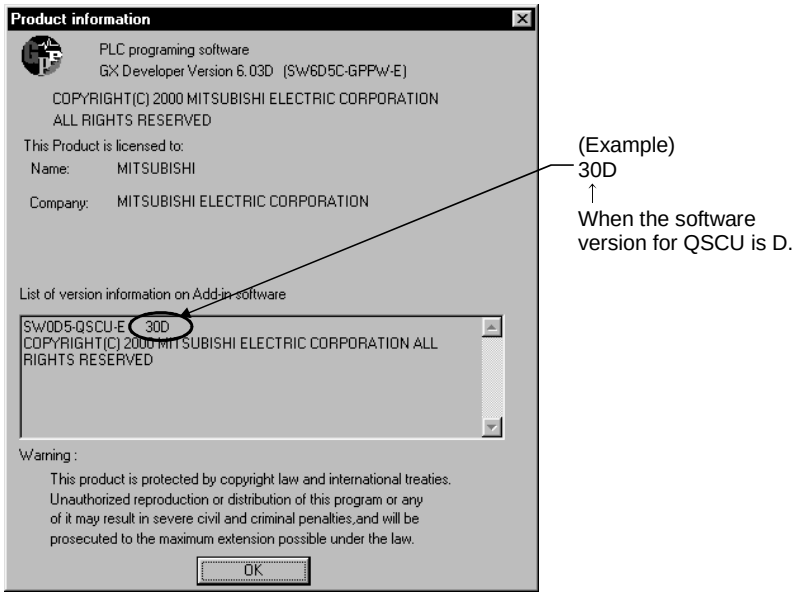
- The corresponding module's serial No. is shown in the Serial No. column.
- The function version of the corresponding module is shown in the Ver. column.

(3) Checking the software version of the intelligent function module

The QSCU software version can be checked on the "Product Information List" screen of the GX Developer.

[Start Procedure]

"Help" → Product Information



(For SW6D5C-GPPW-E)

2 - 12

3 SPECIFICATIONS

The following shows the Q series C24 performance specifications.
See the User's Manual of the QCPU (Q mode) for general specifications.

3.1 Performance Specifications

The following shows the Q series C24 performance specifications. For the transmission specifications when communicating via the modem function, see this section and Chapter 3 of User's Manual (Application).

(1) Transmission specification

Item			Specifications	
			QJ71C24	QJ71C24-R2
Line configuration (Connection) (*2)	RS-232		1:1	
	RS-422/485		1:1, 1:n, n:1, m:n	—
Line configuration (Data communication) (*2)	RS-232	MC protocols communication	1:1, 1:n, m:n	1:1
		Non procedure protocol communication	1:1, 1:n, n:1	1:1
		Bidirectional protocols communication	1:1	1:1
	RS-422/485	MC protocols communication	1:1, 1:n, m:n	—
		Non procedure protocol communication	1:1, 1:n, n:1	
		Bidirectional protocols communication	1:1	
Transmission distance (total distance)	RS-232		Max. 15 m (49.2 ft.)	
	RS-422/485		Max. 1200 m (3937.2 ft.) (total distance)	—
Installation possible station			Q CPU (Q mode), MELSECNET/H remote I/O station	
Number of installation possible modules per station			Max. 64 (Installation is possible within the I/O signal points)	
Dielectric withstand voltage			Depends on the specifications of the loaded station's power supply module	
Insulation resistance				
Noise durability				
Flash ROM write count			Maximum 100000 times to the same area	
Number of I/O occupied points			32 (occupy one slot) (*3)	
Recommended cable	RS-232		7/0.127 □P HRV-SV…Outside diameter 8.5 mm (0.33 in.) or more (Oki Electric Cable Co., Ltd…Number of pairs designated in □.)	
	RS-422/485		SPEV (SB)-MC-0.2 × 3P… Outside diameter Approx. 6.5 mm (0.26 in.) SPEV (SB)-0.2 × 3P…… Outside diameter Approx. 7.5 mm (0.3 in.) (Both MITSUBISHI CABLE INDUSTRIES, Ltd.) (*4)	
Connector applicable for external wiring			9-pin D sub (male) screw-in type (*5)	
5 V DC internal consumption (A)			0.31	0.26
Weight (kg{lb.})			0.20 (0.44)	
External dimensions (mm{in.})			98 (3.9) (H) × 27.4 (1.1) (W) × 90.5 (3.6) (D)	

*1 Set to transfer data with external devices by full-duplex communications system when the Q series C24 is started. Switch to half-duplex communications system as described in User's Manual (Application).

*2 Indicates possible combinations when connecting the PLC CPU and external devices (external device side: PLC CPU side). The total number of n and m+n is up to 32 stations.

*3 In order to use the Q series C24, it is necessary to perform a switch setting using GX Developer. To do so, perform an I/O assignment (32 points for intelligent functional module) for the Q series C24. Set the model type to "QJ71C24" or "QJ71C24-R2" that corresponds to the module loaded.

*4 Recommended cables SPEV (SB)-MPC-0.2 × 3P and SPEV (SB)-0.2 × 3P have the same electrical characteristics, but their external dimensions and internal wire colors are different.

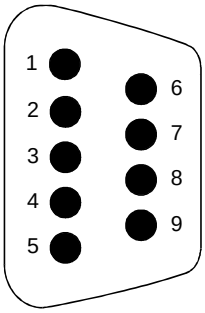
*5 See Section 3.2.1 (3) for the recommended connector.

3.2 RS-232 Interface Specification

The following shows the RS-232 interface specifications.

3.2.1 RS-232 connector specifications

The following shows the specifications of the RS-232 connector that connects the Q series C24 to an external device.



Pin number	Signal abbreviation	Signal name	Signal direction C24 ⟷ External device
1	CD	Carrier detect	←
2	RD(RXD)	Receive data	←
3	SD(TXD)	Send data	→
4	DTR(ER)	Data terminal ready	→
5	SG	Signal ground	⟷
6	DSR(DR)	Dataset ready	←
7	RS(RTS)	Request to send	→
8	CS(CTS)	Clear to send	←
9	RI(CI)	Call Indicate	←

(1) The control signals are described below. (The pin numbers of the connector are enclosed in parentheses.)

1) CD signal (1)

- The Q series C24 operates according to the setting CD terminal check (see Section 8.4.5) of the Q series C24.

	CD terminal check enabled	CD terminal check disabled
Full-duplex communication	• The Q series C24 performs send and receive processing when the CD signal (receive carrier detection) is ON. • If the CD signal is turned off during data communication, the Q series C24 initializes the transmission sequence.	• The Q series C24 performs send and receive processing regardless of the ON/OFF status of the CD signal. • Data communications is possible with an external device that cannot turn the CD signal ON/OFF.
Half-duplex communication	See Chapter 8 of User's Manual (Application)	Setting impossible.

2) RD signal
This is a signal to receive data.

3) SD signal
This is a signal to send data.

3 - 3

4) DTR signal (4)
   - When communicating data using the non procedure protocol, the Q series C24 turns on or off (on when data is receivable) depending on the amount of unused memory in the OS area allocated for receive data storage, if DTR/DSR control is being performed.
     Read the receive data from the sequence program, as the receive data is stored in the OS area when the DTR signal is OFF.
     If DTR/DSR control is not implements, the DTR signal is always ON.
   - If an MC protocol or bidirectional protocol is performing data communication, the Q series C24 turns ON when communications is enabled.

5) DSR signal (6)
   - During DTR/DSR control, if this signal is OFF, the Q series C24 does not send data to the external device.
     Be sure that this signal is always turned ON when the external device is ready to receive.
   - If DTR/DSR control is not implemented, the DSR signal status is ignored.

6) RS signal (7)
   - The Q series C24 turns ON/OFF the RS signal as shown below.
   - When the communication system is full-duplex communications, if the Q series C24 ready signal (X1E) is ON, the Q series C24 turns ON the RS signal.
   - When the communication system is half-duplex communications, when the Q series C24 sends data to an external device, it turns ON the RS signal.
   - The RS signal is not turned OFF even when the receive data cannot be stored in the Q series C24.

7) CS signal (8)
   - The Q series C24 does not send data to an external device when this signal is OFF.
   - Be sure that this signal is always turned ON when the external device is ready to receive.

8) RI signal (9)
   - The RI signal is used when the modem status is monitored on the Q series C24 side. If should be connected as needed. The RI signal is not needed to be connected when the modem is not connected.

REMARK

The control signals status of DTR, DSR, RS and CD are confirmed by the RS-232 control signal status storage area (address 254H, 264H) of the buffer memory for the Q series C24 or QSCU during the data communication.

Bit position	Buffer memory address	
	CH1 side	CH2 side
	254H	264H
b0	RTS (ON/OFF)	
b1	DSR (ON/OFF)	
b2	DTR (ON/OFF)	
b3	CD (ON/OFF)	
b4	—	
b5	RI (ON/OFF)	
b6 to b15	—	

(2) The ON and OFF states of each signal indicate the following conditions:

	(Output side)	(Input side)
ON	····· 5 V DC to 15 V DC,	3 V DC to 15 V DC
OFF	····· –5 V DC to –15 V DC,	–3 V DC to –15 V DC

(3) Interface connector

The Q series C24 uses the following type of RS-232 interface connector.
9-pin D sub (female) screw fixing type, DDK Ltd. made, 17L-10090-27-D9AC
Use one of the following as a connector shell for the connection cable of the the Q series C24 side (for sizes of installation possible connector shells, see Section 5 of Appendix).

- 3M
  Plug model: 8209-6009 Shell model: 3702-2209 M2.6
- AMP
  Plug model: 747904-2 Shell model: 747515 or 174469-2

3.2.2 RS-232 cable specification

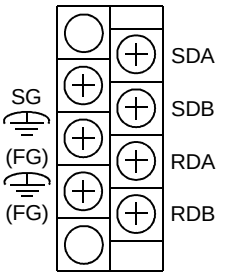
- Use a 15 m (49.21 ft.), or shorter, cable conforming to the RS-232 standard as the RS-232 cable.
  (Recommended cable)
  7/0. 127 □P HRV-SV…□: Designates the number of pairs. (For 13 pairs 7/0.127 13P HRV-SV)
  (Oki Electric Cable Co., Ltd)

3.3 RS-422/485 Interface Specifications

The following shows the RS-422/485 interface specification.

3.3.1 RS-422/485 terminal block specifications

The following shows the specifications of the RS-422 connector and RS-422/485 terminal block that connect to an external device.



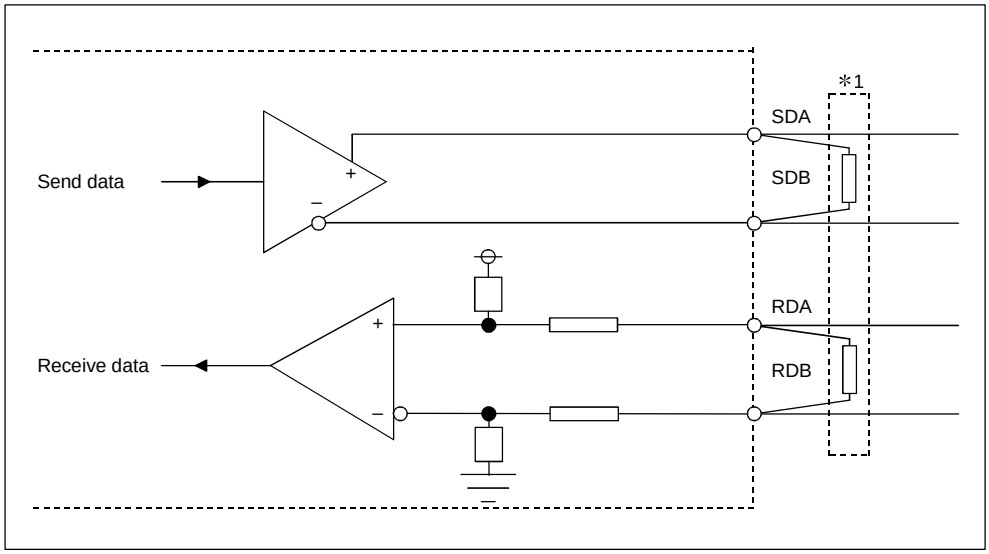
Signal abbreviation	Signal name	Signal direction C24 ⟷ External device
SDA	Send data (+)	→
SDB	Send data (–)	→
RDA	Receive data (+)	←
RDB	Receive data (–)	←
SG	Signal ground	⟷
FG	Frame ground	⟷
FG	Frame ground	⟷

(1) The following describes the control signals.

1) SDA, SDB signals
These are signals to send data from the Q series C24 to the external device.

2) RDA, RDB signals
These are signals for the Q series C24 to receive data from the external device.

(2) The following shows the function block diagrams.
(RS-422/485 interface)



* The following shows the terminal resistor connection.
Connect the terminal resistor according to Section 4.4.2 or the User's Manual (Hardware) of the Q series C24 used.

3.3.2 RS-422/485 cable specifications

The following shows the RS-422/485 cable specification.

(1) Use a 1200 m (3937 ft.), or shorter, cable that satisfies the following specification for the RS-422/485 cable (cable to connect the Q series C24 terminal block).

(2) Make the total distance within 1200 m (3937 ft.) when two or more device are connected in a 1:n or m:n configuration.

(3) The RS-422/485 cable specification is shown below.

Item	Description
Cable type	Shielded cable
Number of pairs	3P
Conductor resistance (20 C°)	88.0 Ω /km or less
Insulation resistance	10000 M Ω - km or more
Dielectric strength	500 V DC, 1 minute
Electrostatic capacitance (1 kHz)	60nF/km or less on average
Characteristic impedance (100 kHz)	110 ± 10 Ω

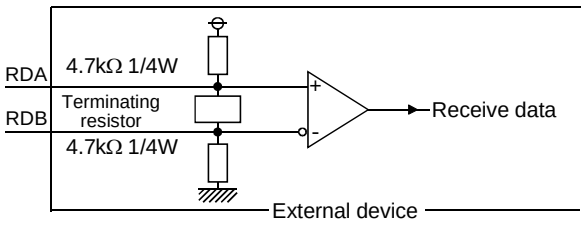
(Recommended cable)
SPEV (SB)-MPC-0.2 × 3P ····· (MITSUBISHI CABLE INDUSTRIES, Ltd.)
SPEV (SB)-0.2 × 3P ····· (MITSUBISHI CABLE INDUSTRIES, Ltd.)
* SPEV (SB)-MPC-0.2 × 3P and SPEV (SB)-0.2 × 3P have the same electrical characteristics, but different external diameter and internal wire colors.

3.3.3 Precautions when transferring data using RS-422/485 circuit

The following precautions must be observed when transferring data with an external device through the Q series C24 RS-422/485 interface.
Take the following into account when the transferring data with the external device.

(1) Error receive data countermeasures at external device during RS-422/485 connection

If the external device may receive erroneous data, install a pull-up or pull-down resistor to the external device as follows.
Installing a pull-up or pull-down resistor (resistance value criteria: approx. 4.7 kΩ 1/4 W) can prevent the reception of erroneous data.



POINT

When there is a pull-up or pull-down resistor at the external device, erroneous data is not received.

REMARK

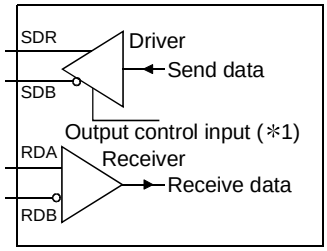
The following describes the case when a pull-up or pull-down resistor is not installed to the external device.
When no station is sending, the send line becomes high impedance and noise, etc. may cause the send line to change and the external device to receive erroneous data.
In this case, there is probably a parity error or framing error.
Therefore, skip the erroneous data.
Since the first data during data reception is fixed in the following cases, also skip the receive data until the fixed head data is received.

- When using an MC protocol to send data, the first data is fixed according to the frame and format the user uses.
- When transferring data using user frames with non procedure protocol or bidirectional protocol, the first data is selected according to the user frame that the user registers to the Q series C24.

(2) RS-422/485 interface operation

1) RS-422-485 interface construction

The following illustration shows the construction of the Q series C24 RS-422/485 interface driver (send)/receiver (receive).



*1 "Output control input" (also called send gate) of the driver (send) section of the illustration at the left determines whether or not data from SDA/SDB is output to the outside.

2) RS-422/485 interface operation

When the "Output control input" in the illustration above is ON, the interface enters the low impedance state (state in which data can be sent).
When the "Output control input" is OFF, the interface enters the high impedance state (state in which data cannot be sent).

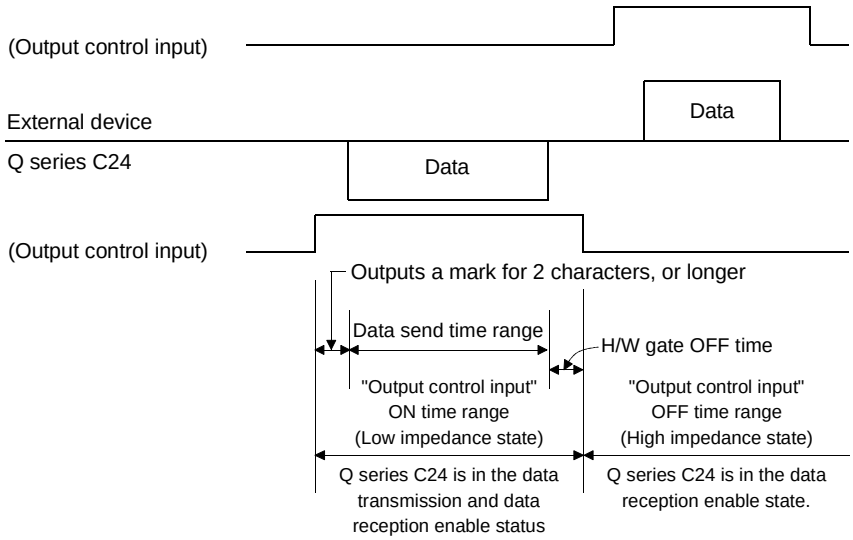
3) Timing to start sending and to complete the transmission processing for the Q series C24

- Timing to start sending

  During data transmission, the Q series C24 outputs the actual data after sending a mark for 2 characters, or longer, after the high impedance set by the operations described in 1) and 2) above is reset.

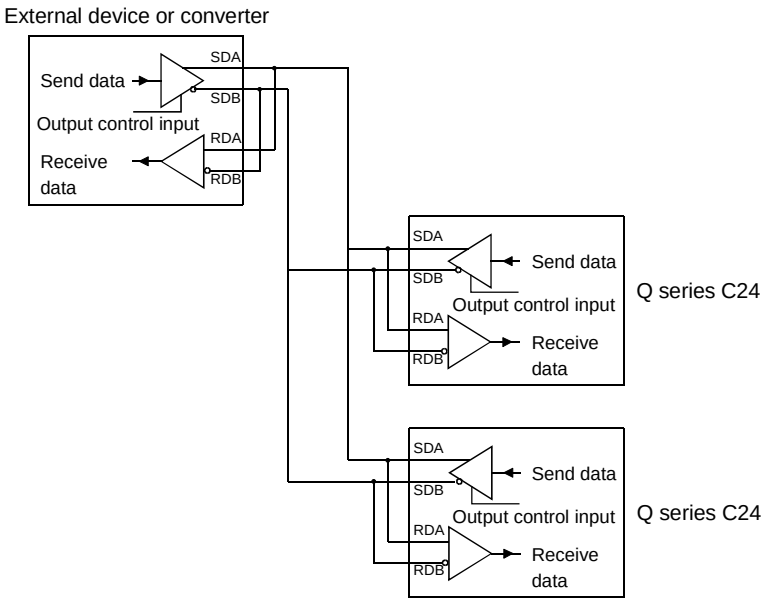
- Timing to complete the transmission processing

  the Q series C24 requires several μs as H/W gate OFF time from the data transmission completion until the transmission processing completion (put it in the high impedance state).



POINT

(1) When the external device and the Q series C24 connected in n:1 and m:n configurations
When the send signal of each device is connected as shown below, if the "Output control input" is turned ON at two or more devices, the relevant devices output (send) data at the same time.
For the external device to transfer data normally,
- "Output control input" must be turned ON only when sending data.
- "Output control input" must be turned OFF when not sending data.



(2) When the Q series C24 is used, if operation of the two interfaces is linked (see Section 4.5.2 (2)), the time to send one character becomes the Q series C24 H/W gate OFF time.
(The Q series C24 turns OFF the gate after the one-character send time.)
＊ Only QJ71C24 can perform linked operation between two interfaces:

3.4 Serial Communication Module Function List

The following table lists the functions of the Q series C24.

Function				Reference section
Communication using MC protocol (*1)	Communication with ASCII code	Communication with QnA compatible 3C frame	Formats 1 to 4 exist for each.	Chapter 5 Reference Manual
		Communication with QnA compatible 4C frame		
		Communication with QnA compatible 2C frame		
		Communication with A compatible 1C frame		
	Communication with binary code	Communication with QnA compatible 4C frame	Format 5	
	Read/write of device memory	Batch read/write in bit/word units		
		Monitoring of device memory		
		Batch read/write of multiple blocks		
		Read/write by extension designation		
		Accessing other stations via network system		
	Reading/writing from/to the buffer memory of the Q series C24			
	Reading/writing from/to the buffer memory of intelligent function modules			
	Reading/writing from/to sequence program files			
	Monitoring the PLC CPUs (PLC CPU monitoring function)			
	Status control of the PLC CPUs (remote RUN/STOP, etc.)			
	Turning on/off input signals of the Q series C24 from an external device (global function)			
	Data transmission from a PLC CPU to an external device (on-demand function)			
Communication using non procedure protocol (*2)	Data transmission/reception in any format			Chapter 6
	Data transmission/reception using user frames			User's Manual (Application)
	Data reception by interrupt programs			
	Monitoring the PLC CPUs (PLC CPU monitoring function)			
	ASCII data transmission/reception by ASCII-BIN conversion			
	Data transmission/reception by specifying transparent code			
Communication using bidirectional protocol (*1)	Data transmission/reception in any format			Chapter 7
	Data reception by interrupt programs			User's Manual (Application)
	ASCII data transmission/reception by ASCII-BIN conversion			
	Data transmission/reception by specifying transparent code			
Communication via public network, etc. (modem function)				
Transmission control	DC code control (including Xon/Xoff control)			
	DTR/DSR (ER/DR) control			
Communication protocol switching				
Independent/linked operation of each interface				Section 4.5.2
Monitoring/testing of initial settings and setting values with utility software				Chapter 8
Supporting multiple PLC system				Section 2.10 of Reference Manual
Remote password check				Section 3.3.3 of User's Manual (Application)

*1 If the external device is capable of incorporating a program and communicating data using a protocol of the MELSEC PLC, it is possible to access the PLC CPU using the above mentioned MC protocol. Furthermore, it is possible to transfer any data using the bidirectional protocol.

*2 When it is necessary to communicate using the protocol of an external device, such as a measuring instrument or a bar code reader, the above-mentioned non procedure protocol is used for data communication. In that case, the processing of the communication data becomes easier by using the user frame communication function.

3.5 Dedicated Instruction List

The following table lists dedicated instructions that can be used in the Q series C24.

○ : Available × : Not available

Classification	Instruction	Description		Protocol			Reference section
				MC	Non	Bi	
For data communication	ONDEMAND	Sends data with the on-demand function		○	×	×	Chapter 9
	OUTPUT	Sends designated number of data		×	○	×	
	INPUT	Receives data (reads received data)		×	○	×	
	BIDOUT	Sends data		×	×	○	
	BIDIN	Receives data (reads received data)		×	×	○	
	SPBUSY	Reads the status of data sent/received with each dedicated instruction		○	○	○	
	CSET	Allows clearing data received up to the present without interrupting the data transmission processing.		×	○	×	
	BUFRCVS	Receives data with an interrupt program (reads received data)		×	○	○	Chapter 16 of User's Manual (Application)
	PRR	Sends data with user frames using transmission schedule table		×	○	×	
Setting value registration/ reading	PUTE	Stores user frames in flash ROM of the Q series C24 (writing)		○	○	○	
	GETE	Reads user frames stored in flash ROM of the Q series C24		○	○	○	
PLC CPU monitoring instructions	CSET	Performs PLC CPU monitoring registration	For PLC CPU monitoring function	○	○	×	
		Cancels PLC CPU monitoring					
Initial value setting instruction		Sets the unit for the number of communication data (words/bytes) and the data communication area				○	

∗ Abbreviations used in the Protocol column
MC : MC protocol
Non : Non procedure protocol
Bi : Bidirectional protocol

3.6 Utility Package (QSCU) Function List

The following table lists the utility package function for the Q series C24.

(○ : Protocol for which setting is valid)

Function			MC	Non-procedure protocol	Bidirectional protocol	Explanation page	Remarks
Auto refresh setting		Refresh the Q series C24's error codes and set devices on the PLC CPU side.	○	○	○	Section 4.6	Can be used via online operation. Can be used via offline operation.
User frame		Register the user frame in the flash ROM.	○	○	—	Section 8.4.1	
Data for modem initialization		Register the data for modem initialization in the flash ROM.	○	○	○	Section 8.4.2	
Data for modem connection		Register the data for model connection in the flash ROM.	○	○	○	Section 8.4.3	
Modem function system setting		Register the system setting values for model function in the flash ROM.	○	○	○	Section 8.4.4	
System setting	CHn Transmission control and others system setting	Set the transmission specifications with the other device. DTR/DSR control, DC code control, communication method, data communication monitoring timer value, etc.	○	○	○	Section 8.4.5	
	CHn MC protocol system setting	Assign the buffer memory for on-demand function, set the user frame number, etc.	○	—	—	Section 8.4.6	
	CHn Non procedure system setting	Assign the buffer memory needed to perform data communication using the non procedure protocol, and change the setting values, etc.	—	○	—	Section 8.4.7	
	CHn Bidirectional system setting	Assign the buffer memory needed to perform data communication using the bidirectional protocol, and change the setting values, etc.	—	—	○	Section 8.4.8	
	CHn PLC CPU monitoring system setting	Set the PLC CPU monitoring function.	○	○	—	Section 8.4.9	
	CHn Transmission user frame No. designation system setting	Set the user frame number to be transmitted, etc.	—	○	—	Section 8.4.10	
System setting default		Reset the setting values in the buffer memory to their default values.	○	○	○	Section 8.4.11	Can be used only via online operation.
System setting write		Write the setting values in the buffer memory to the flash ROM.	○	○	○	Section 8.4.11	
Flash ROM write allow/prohibit designation		Set whether to allow or prohibit writing to the flash ROM.	—	—	—	Section 8.4.12	
X · Y monitor/test		Perform the monitoring/testing of I/O signals to/from the PLC CPU.	○	○	○	Section 8.6.1	
Modem function monitor/test		Monitor the execution status of the modem function.	○	○	○	Section 8.6.2	
Monitor	CHn Transmission control and others monitor	Monitor the status of interface control signals, values set from the GX Developer, etc.	○	○	○	Section 8.6.3	
	CHn MC protocol monitor	Monitor the data communication result, I/O signal status, and setting values in the buffer memory.	○	—	—	Section 8.6.4	
	CHn Non procedure monitor/test		—	○	—	Section 8.6.5	
	CHn Bidirectional monitor		—	—	○	Section 8.6.6	
	CHn PLC CPU monitoring monitor	Monitor the setting values and operating status of the PLC CPU monitoring function.	○	○	—	Section 8.6.7	
	CHn User frame No. designation monitor for transmission	Monitor the setting value for user frame to be transmitted.	○	○	—	Section8.6.8	
Monitor others		Monitor the data reception result, error occurrence status, etc.	○	○	○	Section 8.6.9	
ERR LED off		Turn off the ERR LEDs on the front face of the module.	○	○	○	Section 8.6.10	
Non procedure protocol receive data clear		Clear the currently received data.	—	○	—	Section 8.7	

3.7 List of GX Developer Setting Items for Serial Communication Modules

The following table lists the parameters that are set using the GX Developer.

Parameter setting item	Parameter description	Set data		Reference section
I/O assignment setting	Performs I/O assignment for the Q series C24 and enables the switch settings listed below.	Type		Section 4.5.1
		Model name		
		Points		
		Start X/Y		
Switch setting	Switch 1	CH1 Transmission setting		Section 4.5.2
		CH1 Communication rate setting		
	Switch 2	CH1 Communication protocol setting		
	Switch 3	CH2 Transmission setting		
		CH2 Communication rate setting		
	Switch 4	CH2 Communication protocol setting		
	Switch 5	Station number setting		
Interrupt pointer setting	Performs setting for reading reception date with interrupt programs.	CPU side	Interrupt pointer Start No.	Section 4.5.3
			Interrupt pointer No. of units	
		Intelligent module side	Start I/O No.	
			Start SI No.	
Remote password settings	Sets the remote password and the Q series C24 that performs the check.	Password settings		Section 3.3.3 of User's Manual (Application)
		Password active module settings	Model name	
			Start XY	

3 - 14

3.8 List of Input/Output Signals for the PLC CPU

This section describes the input/output signals of the Q series C24.
For assignments of the input/output signals shown in the table below, it is assumed that the Q series C24 is mounted in slot 0 of the basic base unit.
Device numbers starting with X indicate input signals from the Q series C24 to the PLC CPU, and device numbers starting with Y indicate output signals from the PLC CPU to the Q series C24.
The following table lists the input/output signals for the PLC CPU.

Device number	Signal description	Reference section	Device number	Signal description	Reference section
X0 ＊1	CH1 Transmission normal completion ON: Normal completion	Section 8.6.4 Section 8.6.5 Section 8.6.6	Y0	CH1 Transmission request ON: Requesting transmission	—
X1 ＊1	CH1 Transmission abnormal completion ON: Abnormal completion		Y1	CH1 Reception data read completion ON: Data read completed	
X2 ＊1	CH1 Transmission processing ON: Transmission in progress		Y2	CH1 Mode switching request ON: Requesting switch	Application, Chapter 15
X3 ＊2	CH1 Reception data read request ON: Requesting read	Section 6.1 Section 7.1 Section 8.6.5 Section 8.6.6	Y3	Use prohibited	—
X4 ＊2	CH1 Reception abnormal detection ON: Abnormal detection		Y4		
X5	(For system)	—	Y5		
X6 ＊3	CH1 Mode switching ON: Switching	Application, Chapter 15	Y6

Device number	Signal description	Reference section	Device number	Signal description	Reference section
X1A	CH1 Global signal ON: Output instructed	Section 3.10, Reference	Y1A	Use prohibited	—
X1B	CH2 Global signal ON: Output instructed		Y1B		
X1C	System setting default completion ON: Completed	Section 8.4.11	Y1C	System setting default request ON: Requesting	Section 8.4.11
X1D	(For system)	—	Y1D	Use prohibited	—
X1E ＊4	QJ71C24 (-R2) ready ON: Accessible	—	Y1E		
X1F ＊5	Watchdog timer error (WDT error) ON : Module error occurred OFF: Module being normally operated	—	Y1F		

＊1 The device does not turn on/off by execution of a dedicated instruction when a function that corresponds to the input signal is used.

＊2 The device does turn on/off by execution of a dedicated instruction when a function that corresponds to the input signal is used (from ON to OFF: Data read completed).

＊3 Do not request data communication to the target interface while switching modes (X6 and XD are ON).
(The data communication processing of the Q series C24 is stopped while switching modes.)

＊4 The QJ71C24 ready signal indicates whether or not it is possible to access the Q series C24 from the PLC CPU.
Use it as a interlock signal for a sequence program.
(It turns on about one second after turning the power ON and reset operation.)

＊5 Restart the PLC CPU when the watchdog timer error signal is turned on (reset the power and the CPU module).

IMPORTANT

(1) Of the input/output signals to the PLC CPU, the signals marked with "Use prohibited" must not be output (ON).
If any of the "Use prohibited" signals is output, the PLC system may malfunction.

(2) When the modem function is not used, X10 to X16 become reserved for the system and Y10 to Y16 become use prohibited.

POINT

(1) The input/output signals shown in this section are the signals used when a QnA series serial communication module program is utilized for the Q series C24 (see Section 2 in appendix).
In the QCPU, the on/off of input/output signals to intelligent function modules is executed with a dedicated instruction.
It is not necessary to turn the signals on/off by the sequence program, except for the input/output signals shown in the programming of each function reference page.

(2) When a program for a QnA series serial communication module is also utilized for the Q series C24, it is recommended to replace the instructions with the dedicated instructions shown on the corresponding function reference page of each manual for the Q series C24.

3.9 List of Applications and Assignments of the Buffer Memory

This section describes the buffer memory.

(1) Configuration of the buffer memory

A buffer memory consists of a user area and a system area, as shown below.

(a) User area

1) This is the area where users write/read data.
2) The user area consists of areas for storing setting values for data communication, for actual data communication, and for storing communication status and communication error information.
3) Data read/write to the user area should be performed following the instructions in the corresponding detailed reference page.

(b) System area

This area is used by the Q series C24 system.

(2) List of buffer memory assignments

A buffer memory is configured with 16 bits per address.
Name, default value, etc. of each address of the buffer memory is shown in the lists on the following pages.

1) Abbreviations in the target Protocol column
   MC : MC protocol
   Non: Non procedure protocol
   Bi : Bidirectional protocol
2) Meaning of symbols shown in the target Protocol column
   The following symbols are assigned to protocols related to the setting values of a corresponding area and to areas used for controlled with user settings, and indicate what kind of access is allowed to the area in question.
   RW : Area where it is possible to read/write from/to the PLC CPU and an external device.
   R : Area where only reading is possible from the PLC CPU and an external device.
   – : System area used by the system or area not used by the corresponding protocol.
3) Meaning of symbols shown in the Registration allowed/not allowed column
   Indicates whether or not it is possible to use a value in the corresponding area by registering it to the flash ROM of the Q series C24.
   Allowed : Area that can be registered and used.
   Not allowed : Area that cannot be registered.

IMPORTANT

Do not write data in the "System area" of the buffer memory.
If data is written to any of the system areas, the PLC system may malfunction.
Some of the user areas are partially system areas. Care must be taken when performing read/write to the buffer memory.

POINT

(1) Use the FROM/TO instructions or other applicable commands to access the buffer memory shown in this section when a program for a QnA series serial communication module is utilized for the Q series C24 (see Section 2 in Appendix).
In QCPU, the access to the buffer memory of an intelligent function module is executed with a dedicated instruction.
It is not necessary to access directly using the FROM/TO instructions or other instructions from the sequence program, except when accessing the buffer memory as shown in the programming on each function reference page.

(2) When a program for a QnA series serial communication module is utilized for the Q series C24, it is recommended to replace the instructions with the dedicated instructions shown on the corresponding function reference page of each manual for the Q series C24.

(3) The following initial settings (changing the default values) for data communication must be performed by a registration operation using QSCU or by executing the CSET instruction for the sequence program.

1) Initial settings for communication using the MC protocol
   - Setting the unit of data length sent by the on-demand function
     Word/byte units designation (addresses 150 (96H), 310 (136H))
   - Setting the buffer memory used by the on-demand function
     Buffer memory head address designation (addresses 160 (A0H), 320 (140H))
     Data length designation (addresses 161 (A1H), 321 (141H))

2) Initial settings for communication using the non procedure/bidirectional protocols
   - Setting the unit of data length to be sent and received
     Word/byte units designation (addresses 150 (96H), 310 (136H))
   - Setting the transmission area
     Transmission buffer memory head address designation (addresses 162 (A2H), 322 (142H))
     Transmission buffer memory length designation (addresses 163 (A3H), 323 (143H))
   - Setting the reception area
     Receive buffer memory head address designation (addresses 166 (A6H), 326 (146H))
     Receive buffer memory length designation (addresses 167 (A7H), 327 (147H))

✻ For more details on the registration operation by QSCU, see the explanation of the system settings of the corresponding protocol in Sections 8.4.5 to 8.4.8.
For more details on the CSET instruction, see Section 16.4 of the User's Manual (Application).

4 SETTINGS AND PROCEDURES PRIOR TO OPERATION

This chapter explains the settings and procedures required before starting a system that uses the Q series C24.

POINT
(1) When using the Q series C24, please read the safety precautions at the beginning of this manual. (2) The installation and setup methods of the Q series C24 are the same as those for CPU modules. (3) For module installation and setup, see the user's manual for the PLC CPU used.

4.1 Handling Precautions

The following explains the precautions for handling the Q series C24:

(1) Do not drop the module or subject it to heavy impact since it is made of resin.

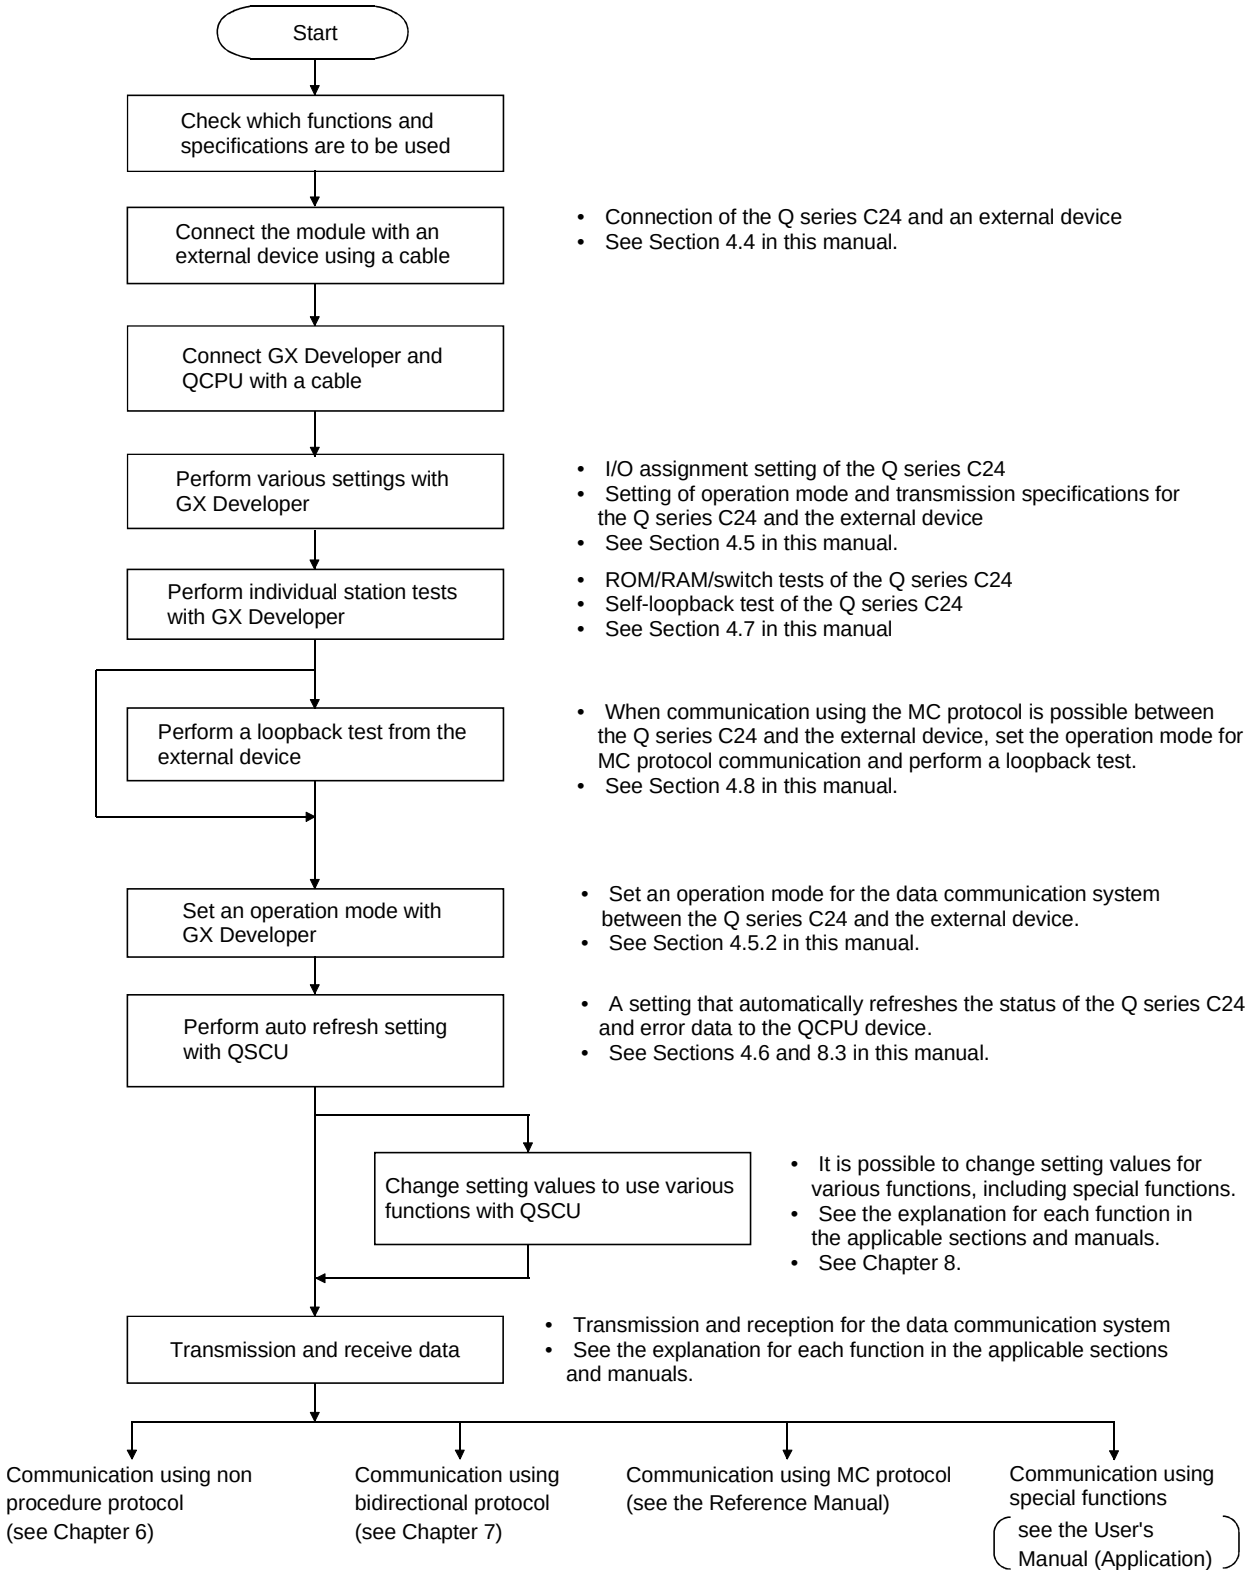
(2) Tighten the module terminal and fixing screws within the specified clamping torque range as follows:

Screw	Clamping torque range
RS-422/485 terminal block terminal screws (M3)	42 to 58 N · cm
Module fixing screw (not necessary for standard use) (M3) (*1)	36 to 48 N · cm

*1 A module can be easily fixed to a base unit using the hooks in the upper part of the module. However, it is recommended that the module will be fixed using the module mounting screws when it is used in a place subject to vibration or impact.

4.2 Settings and Procedures Prior to Operation

The outline of the procedure before operation is shown below.



4.3 Part Names and Functions

	Name	Description
1)	Displayed LED	Displayed LED (see (1) for description.)
2)	RS-232 interface on CH1 side	RS-232 interface on CH1 (D-sub 9 pin) for performing serial communication with an external device.
3)	RS-422/485 interface on CH2 side	RS-422/485 interface on CH2 (two piece terminal block) for performing serial communication with an external device.
4)	RS-232 interface on CH2 side	RS-232 interface on CH2 (D-sub 9 pin) for performing serial communication with an external device.

(1) List of LEDs displayed

CH	LED name	Description	● : Lit/flashing	○: Off	Supported protocol		
					MC	Non procedure protocol	Bidirectional protocol
—	RUN	Normal operation display	Normal	Abnormal, reset	○		
	ERR	Error existence display (＊1)	Error occurrence	Normal			
CH1	NEU	Neutral status display on CH1 side (＊2)	Waiting to receive MC command message	Receiving command message	○	×	
	SD	Send data status display	Sending data	Not sent	○		
	RD	Receive data status display	Receiving data	Not received			
CH2	NEU	Neutral status display on CH2 side (＊2)	Waiting to receive MC command message	Receiving command message	○	×	
	SD	Send data status display	Sending data	Not sent	○		
	RD	Receive data status display	Receiving data	Not received			

＊1 This LED is lit when there is a hardware error in the Q series C24 or error in the data communication (see Chapter 10).

＊2 These LEDs display the status of the data communication using the MC protocol.
Lit : Waiting to receive a command message from the external device.
Off : Processing a command message received from the external device.

4.4 External Wiring

This section explains wiring between the Q series C24 and external device.

As the wiring precautions, external wiring which is resistant to the effects of external noise is a prerequisite for reliable system operation and full use of the Q series C24 function.

(1) Ground the shield at only one point.

(2) When connecting with an external device using an RS-232 line, use a connector shell as specified in Section 3.2.1 on the Q series C24 side.

(3) The RS-422/485 interface terminal block uses M3 terminal screws.
Fasten suitable sized crimped terminals to the terminals.

(4) Connect the external device according to its specifications.

(5) See Appendix 5 for the bend radius of the connection cable.

4.4.1 Connecting the RS-232 interface (full-duplex communications)

The following shows the connection precautions and connection examples when using the Q series C24 RS-232 interface for full-duplex communications.

(1) Connection precautions

(a) For further information about the following items, see the explanation in the applicable section in the User's Manual (Application).

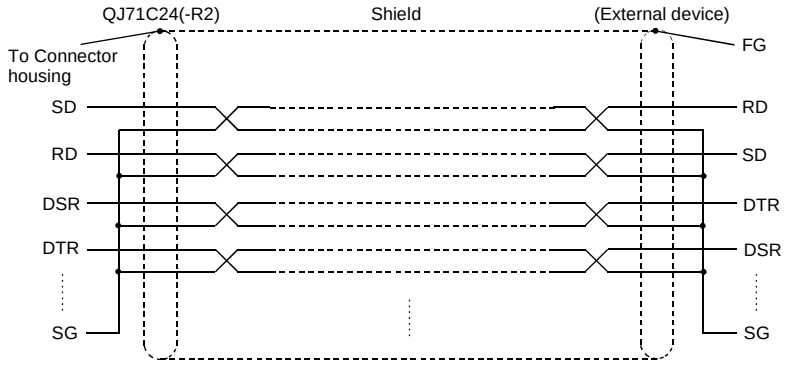
- Controlling the communication on the Q series C24 side by the external device side using the CD signal of the RS-232 interface.
  ✻ This is affected by the "RS-232 CD terminal check setting" in "CHn transmission control and others system setting change" screen on QSCU.
- Performing half-duplex communication using specifications on the external device side (an example of such a connection is shown in this section).
- Using modem functions.

(b) The connection cable FG signal and shield are connected as follows.

	Connection on the Q series C24 side	Notes
Connection cable FG signal	Connect to the Q series C24 connector housing	Do not short the communication cable FG signal and the SG signal. When the FG signal and the SG signal are connected inside the external device, do not connect the FG signal to the Q series C24.
Connection cable shield	Connect to the external device FG terminal or the Q series C24 connector housing	

(c) When normal data communication is not obtained due to external noise, perform the wiring as follows:

1) Connect the FG terminals on the external device and the Q series C24 using the shield of the connection cable.
2) Signals other than SG should be connected with SG signals in the twisted pair.

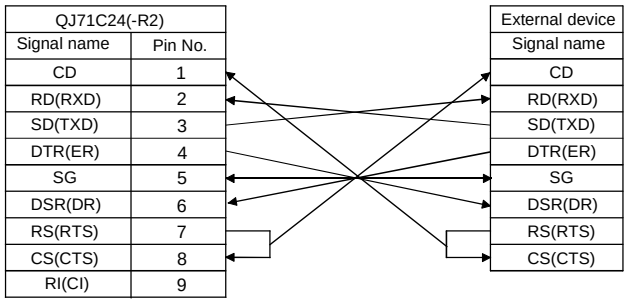


POINT

When using an RS-232 to RS-422 converter to connect the external device and the Q series C24, use a converter that is compatible with the external device and PLC CPU system configuration (1:1).

(2) Connection examples

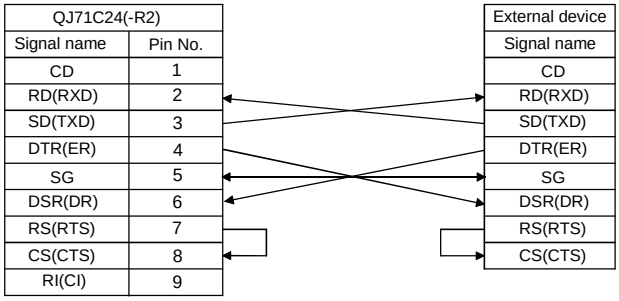
(a) Connection example with an external device capable of turning on and off the CD signal (No. 1 pin)



* The CD terminal check setting is set according to the specification of the external device. When wiring shown above, DTR/DSR control or DC code control may be performed.

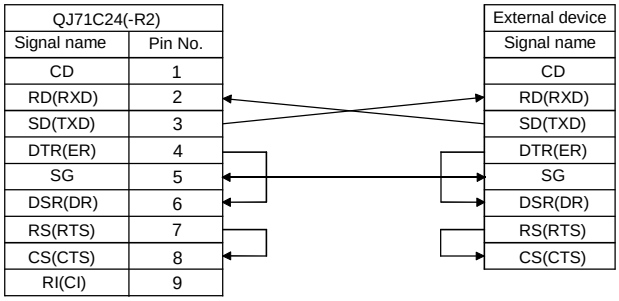
(b) Connection example with an external device not capable of turning on and off the CD signal

1) Connection example 1



* When wiring shown above, DTR/DSR control or DC code control may be performed.

2) Connection example 2



* When wiring shown above, DC code control may be performed.

POINT

If the PLC CPU and an external device cannot be communicated, try to perform data communication as a connection test, using the wiring connection as shown in Connection example 2.
If data can be communicated using the wiring connection shown in Connection example 2, rewire after checking the interface specifications on the external device side.

4.4.2 Connecting the RS-422/485 interface

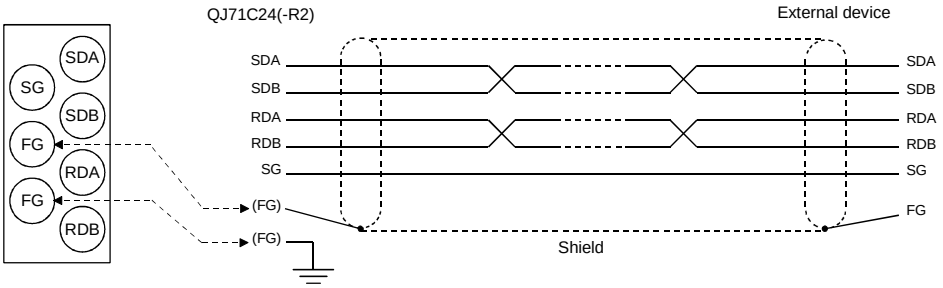
The following shows the connection precautions and connection examples when using the Q series C24 RS-422/485 interface.

(1) Connection precautions

(a) When connecting the Q series C24 SG and FG signals to the external device, connect them according to the specifications of the external device.

(b) Connect the shield of the connection cable to the FG terminal on either of the connected devices.
If normal data communication is not obtained due to external noise even if wiring is made as shown above, perform wiring as follows:

1) Connect between the FG of both stations with the shield of the connection cable.
On the external device side, however, follow the instruction manual of the external device.
2) Connect the (FG) of the Q series C24 side to the FG terminal at the power supply module of the station which has the Q series C24 is installed, or to the FG terminal of the control panel on which the Q series C24 PLC is installed.
3) Connect nnA and nnB of each signal in the connection cable as a pair.

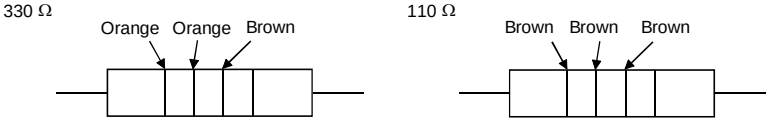


Correspondance of the RS-422/485 terminal block and signal location.

(e) Terminal resistor must be set (or connected) for the station of both ends on the circuit.
Match the Q series C24 to the specifications of the external device and connect a terminal resistor (packed with the Q series C24) according to this section.
Connect, or set a terminal resistor at the external device according to the instruction manual of the external device.
(The terminal resistor to connect to the Q series C24)

- When communications performed using RS-422, "330Ω 1/4 W" resistor is connected.
- When communications performed using RS-485, "110Ω 1/2 W" resistor is connected.

＊ How to discriminate between the terminating resistors



(d) If data cannot be communicated with the external device at all, the polarity of the external device could be wrong and should be checked again. If the polarities of the Q series C24 and the external device do not match, reverse the polarity of each signal on either device side and connect the devices with the cable; this may enable the data to be communicated.

POINT

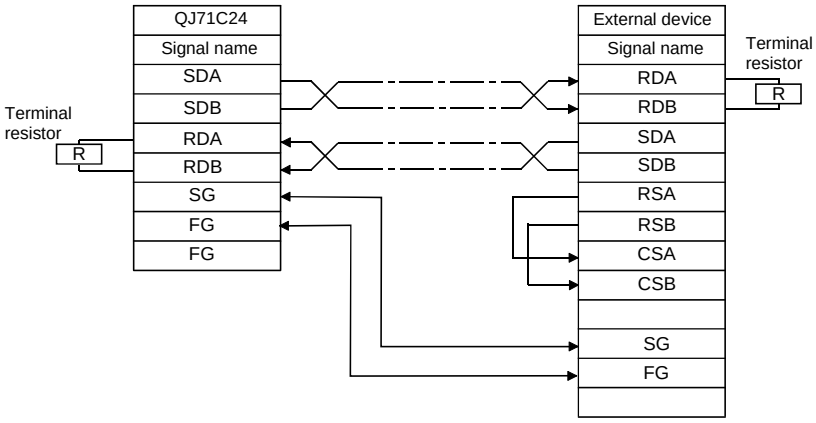
(1) For terminal resistor setting/connection described in this section, when the RS-232 to RS-422 converters or similar device is used at the external device at both ends of the circuit, a terminal resistor must be set, or connected, at the converter.

(2) When using the RS-232C to RS-422 converters to connect the external devices and the Q series C24, use a converter that is compatible with the external device and PLC CPU system configuration (1:1, 1:n, m:n).

(3) Device connected to the Q series C24 RS-422/485 interface must be standardized as RS-422 or RS-485, including 1:n and m:n connections.

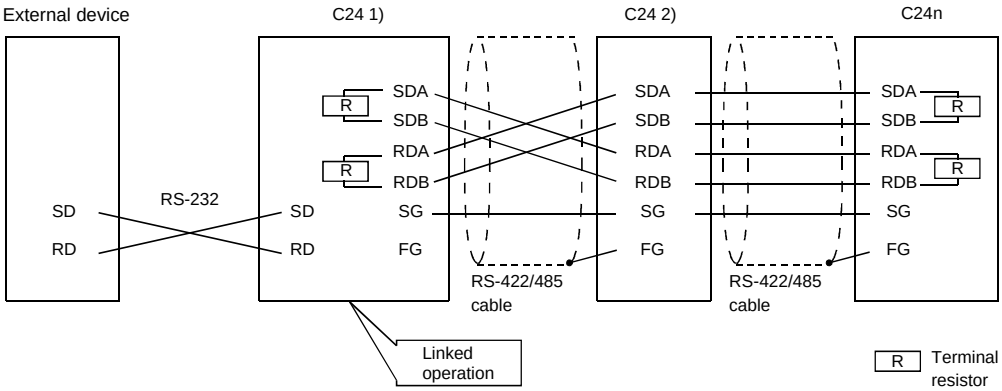
(2) Connection examples

(a) When connected in a 1:1 configuration (external device: Q series C24)

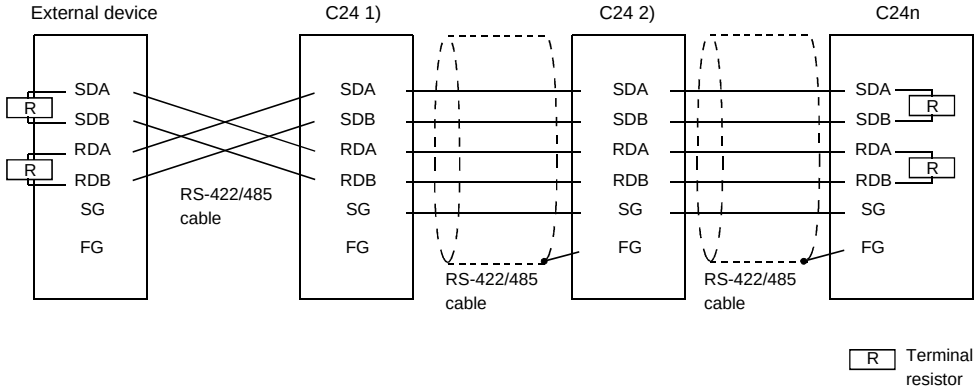


(b) When connected in a 1:n configuration (multidrop connection) (external device: Q series C24)

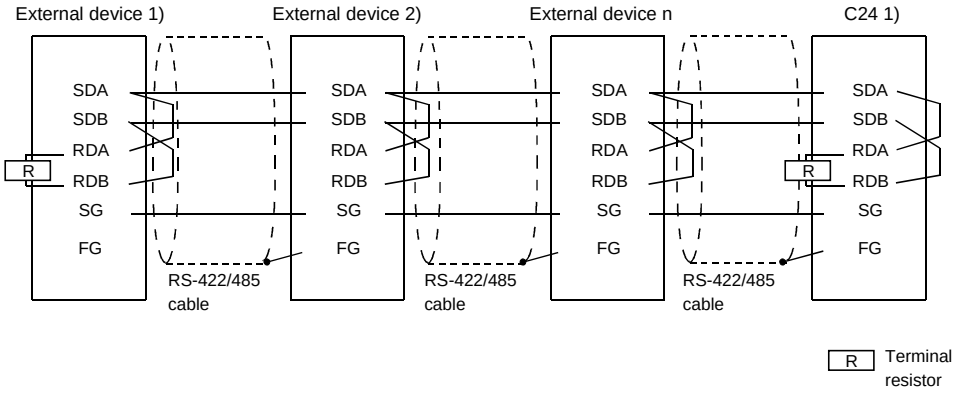
1) Connection example



2) Connection example 2



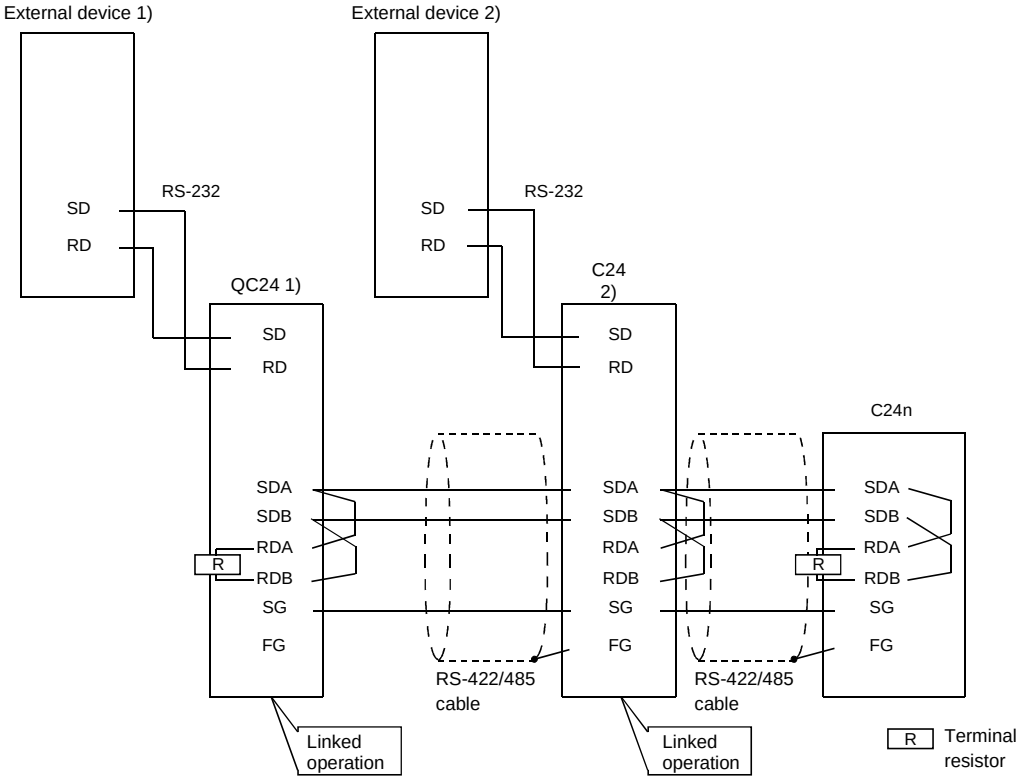
(c) When connected in a n:1configuration (multidrop connection) (external device: Q series C24)



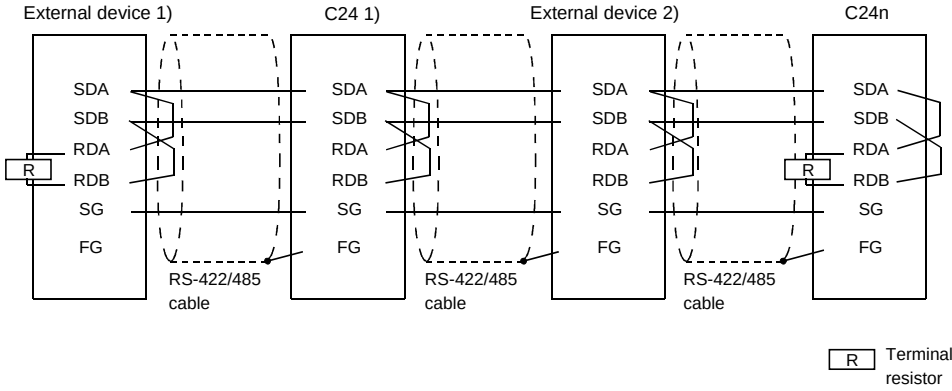
4 - 9

(d) When connected in a m:n configuration (multidrop connection) (external device: Q series C24)

1) Connection example 1



2) Connection example 2



4.5 Settings for GX Developer

This chapter explains various settings via GX Developer that allow the Q series C24 to perform data communication with external devices.
See Section 3.3.3 of the User's Manual (Application) for how to perform the remote password setting.

4.5.1 I/O assignment settings

[Setting purpose]

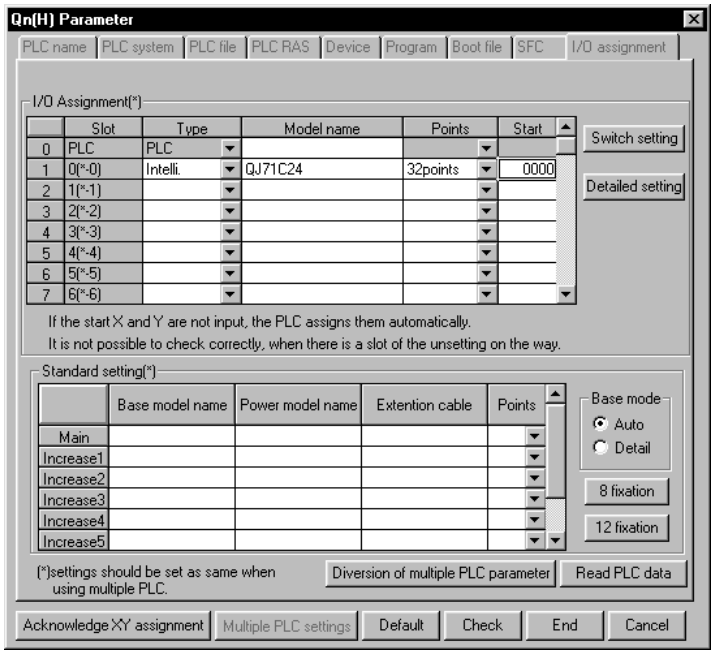
The I/O assignment settings perform the settings for the types of modules to be mounted on a base unit, the range of input/output signals, and switches of the Q series C24.

[Startup procedure]

[GX Developer] → [PLC parameters] → I/O assignment.

For screen display, see the GX Developer Operating Manual.

[Setting screen]



(For SW6D5C-GPPW-E)

[Display description]

Item name		Setting for item	Remarks
I/O assignment	Type	Select "intelli."	—
	Model name	Enter the module model name to be mounted (QJ71C24 or QJ71C24-R2).	
	Points	Select 32 points.	
	Start XY	Enter the start I/O signal (Hexadecimal) for the target module.	
	Switch setting	Set the communication rate, transmission specifications, communication protocol, etc.	See Section 4.5.2.
	Detailed setting	Select the control PLC of the Q series C24 when a multiple PLC system is employed.	See QCPU (Q mode) User's Manual (Function Description/Program Basics)
Multiple PLC settings		Select when using a multiple PLC system.	

4.5.2 Switch settings for I/O and intelligent functional module

[Setting purpose]

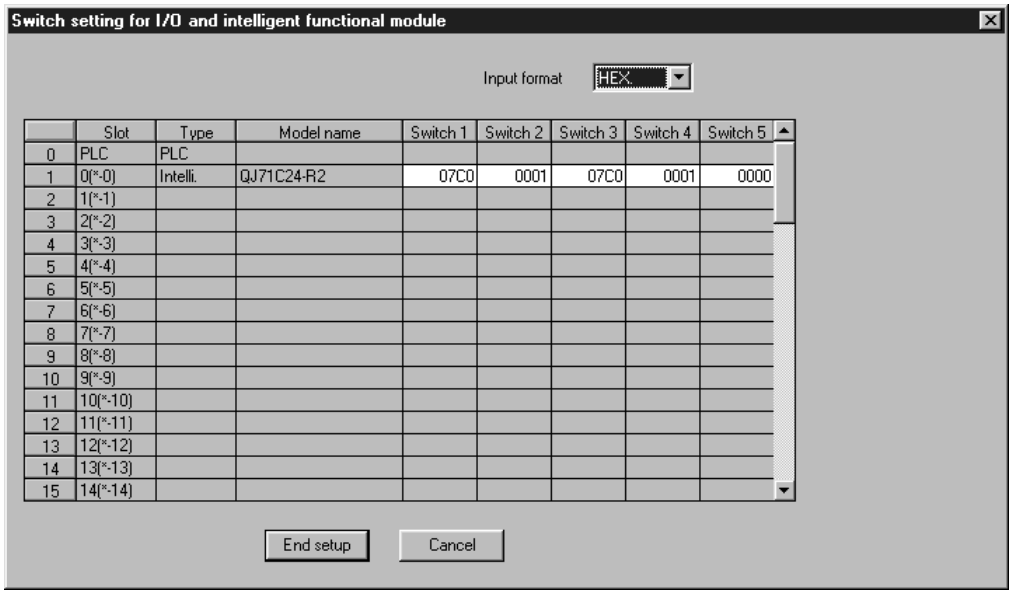
The switch settings for I/O module and intelligent functional module perform the settings for transmission specifications and communication protocol for communicate with external devices.

[Setting procedure]

[GX Developer] → [PLC parameters] → [I/O assignment setting] → Switch setting .

For screen display, see the GX Developer Operating Manual.

[Setting screen]



[Display description]

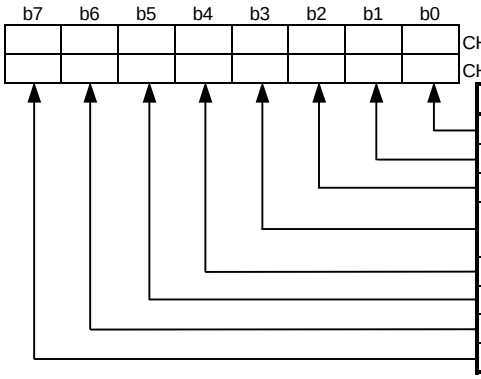
(1) Switches 1 to 5

Set the transmission specifications and communication protocol of each interface using the combinations of setting values for each switch with 16 bit binary data according to the following table.

Switch number	Description		Remarks
Switch 1	b15 to b8	b7 to b0	See a) and b)
	CH1 Communication rate setting	CH1 Transmission setting	
Switch 2	CH1 communication protocol setting		See c)
Switch 3	b15 to b8	b7 to b0	See a) and b)
	CH2 Communication rate setting	CH2 Transmission setting	
Switch 4	CH2 Communication protocol setting		See c)
Switch 5	Station number setting		See d)

∗ For settings to perform linked operation between two Q series C24 interfaces, see (2).

(a) Transmission setting (CH1 side: switch 1 (lower level); CH2 side: switch 3 (lower level))



Bit	Description	OFF (0)	ON (1)	Remarks
b0	Operation setting	Independent	Link	Must be set to OFF on CH1
b1	Data bit	7	8	Parity bit is not included
b2	Parity bit	NO	Yes	Vertical parity
b3	Even/odd parity	Odd	Even	Valid only when parity bit is set to Yes
b4	Stop bit	1	2	—
b5	Sum check code	NO	Yes	—
b6	Write during RUN	Prohibited	Allowed	—
b7	Setting modifications	Prohibited	Allowed	—

* All items listed in the table should be set to OFF for the interfaces for which "GX Developer connection" is set in the communication protocol setting.

1) Operation setting
   - This sets whether to use each of the two Q series C24 interfaces for independent data communication, or to use the two for linked data communication.
   - The setting and data flow for linked operation is explained in (2).
2) Data bit setting
   This sets the bit length for one character in data communicated with an external device according to the specifications of the external device. (When data communication is performed using format 5 of the MC protocol (for binary code communication), it is necessary to set it to 8 bits when processing the sum check code with the bidirectional protocol.)
3) Parity bit setting
   - This sets whether or not a parity bit (vertical parity) is added for one byte of transmission/receive data, according to the specifications of the external device.
   - The addition of the parity bit to the transmission data and the checking of the parity bit of receive data are performed by the Q series C24.
4) Even/odd parity setting
   This sets whether the parity bit (vertical parity) should be odd parity or even parity when adding the parity bit (vertical parity), according to the specifications of the external device.
5) Stop bit setting
   This sets the stop bit length for one character in data communicated with an external device, according to the specifications of the external device.
6) Sum check code setting
   - This sets according to the specifications of the external device whether or not a sum check code is added to transmission and reception messages of each frame and format during data communication using the MC or bidirectional protocol.
   - For an explanation of the message configuration and sum check code when a sum check code is added (set to Yes), see the applicable explanation of each protocol.

7) Write during RUN setting
   - This sets according to the system specifications whether or not data transmitted using the MC protocol is written to the PLC CPU from an external device while the PLC CPU is running.
   - When write during RUN is prohibited (disabled), the data is not written and an NAK message is returned if the external device requests the PLC CPU to write data while it is running.
   - For an explanation of the functions available in this setting, check in the "write allowed setting" and "write prohibited setting" columns in the command list of the Reference Manual.

8) Setting modifications setting
   This sets whether or not the following actions are allowed after starting up the Q series C24.
   Changing data communication functions and transmission
   - Specifications, and the switching mode of each interface
   - Writing data to the flash ROM (writing the system setting values and user frame)

POINT

(1) A setting change in the connected interface side should be set to Allowed, in order to register a user frame to the flash ROM from an external device using the MC protocol.

(2) Setting changes in interfaces on the CH1 and CH2 sides should both be set to Allowed, in order to register the system setting values and user frames to the flash ROM from the PLC CPU.

(b) Communication rate setting (CH1 side: switch 1 (upper level); CH2 side: switch 3 (upper level))

Communication rate (Unit: bps)	Bit position b15 to b8	Communication rate (Unit: bps)	Bit position b15 to b8	Remarks
50	$0F_H$	14400	06_H	Try lowering the communication rate when data cannot be communicated normally with an external device due to overrun errors and framing errors etc.
300	00_H	19200	07_H	
600	01_H	28800	08_H	
1200	02_H	38400	09_H	
2400	03_H	57600	$0A_H$	
4800	04_H	115200	$0B_H$	
9600	05_H	—	—	

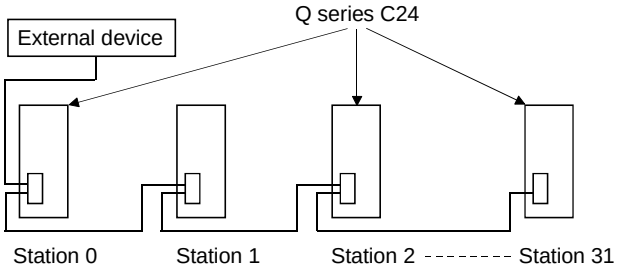
* When the two interfaces are each connected to an external device, set the communication rate so that the total of the two interfaces is 115,200 bps or less.
  When only one interface is connected to an external device, the connected interface can be set to a maximum communication rate of 115, 200 bps. In this case, set the communication rate of the unconnected interface at 300 bps.
* Set "00_H" in the communication protocol settings for interface side for which "GX Developer connection" is selected.

(c) Communication protocol setting (CH1 side: switch 2; CH2 side: switch 4)

Set number	Description		Remarks
0H	GX Developer connection		GX Developer communication rate and transmission specifications are automatically set.
1H	MC protocol	Format 1	For communication with ASCII code in the specified form of an A compatible 1C frame or QnA compatible 2C/3C/4C frame
2H		Format 2	
3H		Format 3	
4H		Format 4	
5H		Format 5	For communication with binary code in a QnA compatible 4C frame
6H	Non procedure protocol		For communication using non procedure protocol
7H	Bidirectional protocol		For communication using bidirectional protocol
8H	For linked operation setting		Set to the CH1 side when CH1 and CH2 interfaces are used in linked operation (operated with the communication protocol of the CH2 side).
9H to DH	Setting prohibited		—
EH	ROM/RAM/switch test		For self-diagnosis of the modules
FH	Individual station loopback test		For checking operation of each interface of the modules

(d) Station number setting (switch 5 (common for both CH1 and CH2 sides))

- This setting is for communication using the MC protocol.
- When several the Q series C24s are connected on the same line with multidrop connection, set the station number designated in the data items of the transmission frame in each external device to 0 to 31 (0H to 1FH).
  ✻ This number designates which external device is to be communicated with the Q series C24.
- Set the station number to 0 when the system configuration of the external device and the PLC CPU is 1:1.



POINT

If the communication of data with external device is to be started, check the specifications of the functions to be used and then make the settings and connect the cables.

Make the following switch settings from the GX Developer if there is to be no communication (if the cables are not to be connected) at the interface.

- Communication protocol setting : Set between 0H and 7H.
- Transmission setting, communication rate setting: Set all to OFF.

(2) The setting and data flow in linked operation

(a) Set the related switches as follows when two Q series C24 interfaces are in linked operation.

Switch number		Settings		Setting value
Switch 1	CH1 side	Transmission setting	Operation setting	b0 = OFF
			Data bit setting	Set each switch on both CH1 and CH2 sides to the same specification.
			:	
		Communication rate setting		Match the external device.
Switch 2		Communication protocol setting		8
Switch 3	CH2 side	Transmission setting	Operation setting	b0 = ON
			Data bit setting	Set each switch on both CH1 and CH2 sides to the same specification.
			:	
		Communication rate setting		Match the external device.
Switch 4		Communication protocol setting		0 to 7
Switch 5		Station number setting		Set according to (d) of (1)

(b) Do not use the above settings for the following cases, because linked operation cannot be performed.

1) When an external device is not connected to either of the interfaces.
2) When the bidirectional protocol is used for data communication.
3) When communicating data with an external device connected to two interfaces that are not interacting, using functions set in the communication protocol settings (MC protocol/non procedure protocol).

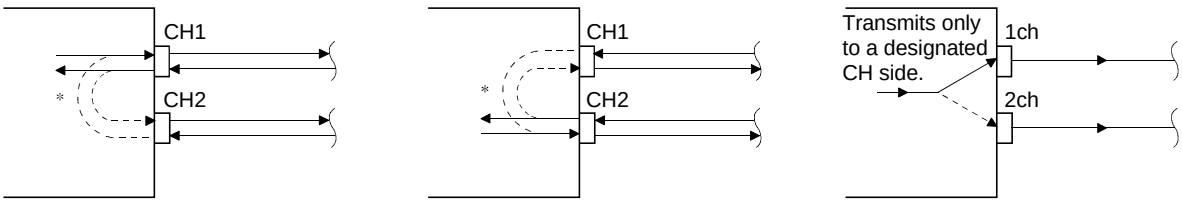
POINT

When two interfaces are in linked operation, the transmission time for one character becomes equal to the hardware gate off time of the Q series C24.

(c) The data flow in linked operation is as follows.

1) Two interfaces operate linked together using functions defined with the communication protocol setting on the CH2 side (MC protocol in the same format or a non procedure protocol) within the transmission specifications set in the respective transmission settings (specifications for CH1 and CH2 must be the same).

Q series C24 (data flow in linked operation)



* In linked operation, all data received from one of the two interfaces is transmitted from the other interface. In this case, exclusive control of the received data is necessary when data is communicated using the non-procedure protocol since all the connected stations receive the data. When data communication is performed using the MC protocol, only the Q series C24 having the station number designated in the message performs the process designated by the command. Furthermore, when data communication is performed using QnA compatible 2C/3C/4C frames of the MC protocol, the header information for linked operation is added to messages directed to other stations linked by multidrop connection.

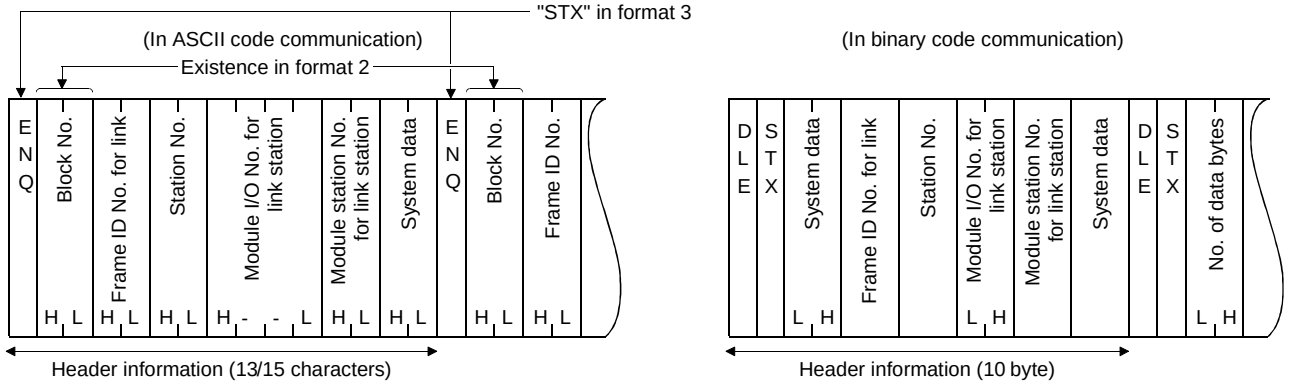
  ⓐ Processing performed by the Q series C24 connected to an external device
  - The header information is added to the command messages received from the external device that are directed to other stations and sends them to the stations through the other interface.
  - The header information is deleted from the response messages received from other stations and sends them to the external device using the other interface.
    (The header information is also sent during m:n connection.)

  ⓑ Operation of the accessed station
  The accessed station processes the request contained in the command message, adds the header information to a response message, and sends it using the interface that received the command message.

REMARK

The following describes the header information that is added by the Q series C24 to a message in linked operation.

1) When communicating with ASCII code (formats 1 to 4)
   The following 13/15 character header information is added immediately before the control code (ENQ/STX/ACK/NAK) at the start of each message (13 characters for formats 1, 3 and 4; 15 characters for format 2).
2) When communicating in binary mode (format 5)
   The following 10 byte header information is added immediately before the control code (DLE + STX) at the start of each message.



4.5.3 The Intelligent function module interrupt pointer setting

The following explains the interrupt pointer setting with GX Developer in order to receive data using an interrupt program.
For the method to receive data using an interrupt program, see User's Manual (Applications) Chapter 4.

[Setting purpose]

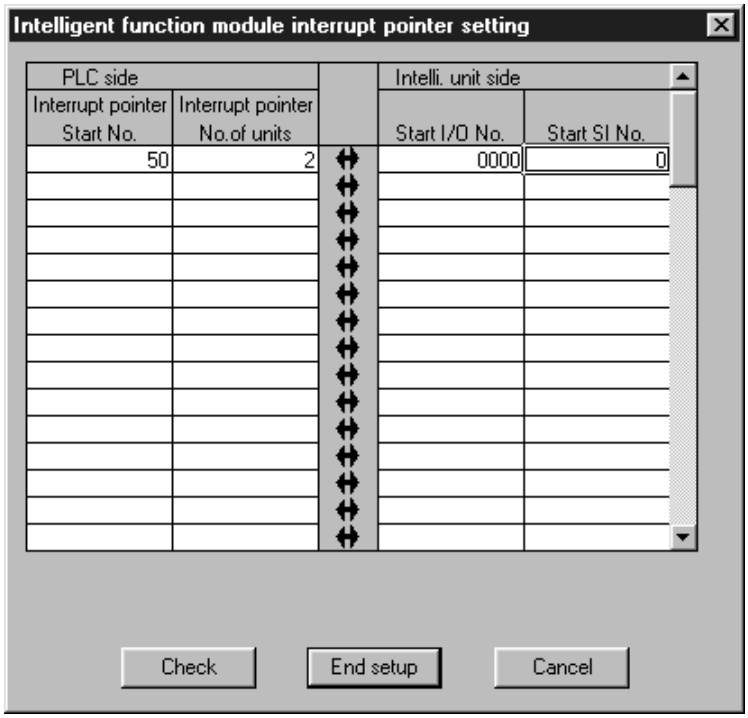
The intelligent function module interrupt pointer sets the information to read the receive data with an interrupt program of the PLC CPU during communication using the non procedural/bidirectional protocol.
By performing this setting, an interrupt program starts when data is received from an external communicating device and the reading of data received by the PLC CPU becomes possible.

[Startup procedure]

[PLC parameters] → [PLC system setting] → Interrupt pointer setting .

For display screen, see the GX Developer Operating Manual.

[Setting screen]



[Setting description]

(1) Interrupt pointer start No. on the PLC side
Set the start number (ranging from 50 to 255) of the interrupt pointer (Ixx) for use in the sequence program.

(2) Interrupt pointer No. of units on the PLC side
Set the number of units (2) of interrupt pointers (I) for use in the sequence program.

(3) Start I/O No. on the intelligent module (unit) side
Set the start I/O No. for the Q series C24.

(4) Start SI No. on intelligent module (unit) side

1) Assign control numbers (SI) on the Q series C24 side to the interrupt pointers (Ixx) used in the sequence program.
2) Set the start SI No. (0) of the interrupt control numbers.
3) The interfaces for data reception corresponding to the interrupt control numbers are as follows:
SI No. 0: for interface on the CH1 side
SI No. 1: for interface on the CH2 side

4 - 19

4.6 Settings with the Utility Package (QSCU)

The settings defined with QSCU for operation of the Q series C24 are described in Chapter 8.

The following concerns the data set from QSCU.

1) Data set in the Q series C24 for the use of specific functions
2) Data set in the PLC CPU to communicate information between the Q series C24 and the PLC CPU of the mounting station.

This section explains the "Auto refresh settings" of the data mentioned in 2) above.

[Setting purpose]

The auto refresh settings are defined to automatically store the error and status information stored in the buffer memory of the Q series C24 in devices designated by the PLC CPU.

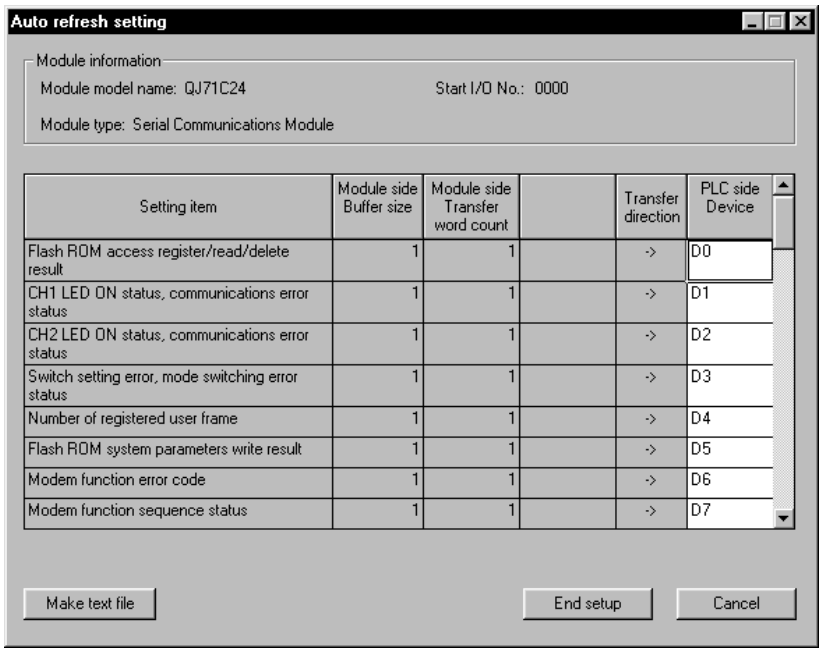
By this setting, the users can see the module error and status information without accessing the Q series C24.

[Setup procedure]

[GX Developer] → [Tools] → [Intelligent function utility] → [Start] → "Intelligent function module parameter setting module select"→ Auto refresh .

For display screen, see Section 8.3.

[Setting screen]



[Setting items]

Setting item		Buffer memory address	Reference section

4 - 21

(1) Devices

(a) Set the word device of the PLC CPU which stores error and status information in the setting item field when using the auto refresh function between the Q series C24 and the PLC CPU.

(b) The devices used must be of the types X, Y, M, L, B, T, C, ST, D, W, R, or ZR.

* If bit devices of types X, Y, M, L, or B are used, a number that can be divided by 16 points (e.g., X30, Y120, M16, etc.) should be specified. The buffer memory data is stored in 16 point units from the specified device number (e.g., if M16 is set, data is stored from M16 to M31).

(c) The device can be set to auto refresh for required information only.

(2) Writing auto refresh settings to QCPU and saving them in a file

(a) Writing auto refresh settings to QCPU
Use GX Developer or online PLC write function of QSCU.

(b) Saving in a file
Use the file storage function shown in the file items in the parameter module selection screen shown in Section 8.3.2. of QSCU.

POINT

(1) The auto refresh settings are stored in the intelligent function module parameter.
After the intelligent function module parameters have been written to the CPU module, it enables the auto refresh setting by turning the power OFF → ON or by resetting the CPU module.

(2) The auto refresh settings cannot be changed from the sequence program. However it is possible to add a process similar to auto refresh by using the FROM/TO command of the sequence program.

4.7 Individual Station Test

After installing the Q series C24 to the base unit of QCPU, perform an individual station test first to check the switch setting (see Section 4.5.2) and operation of the Q series C24.

POINT

(1) When a problem occurs during data communication with an external device, perform an individual station test as described in this section to check whether or not there is any problem in the operation of the Q series C24.

(2) In order to avoid problems, set the PLC CPU to STOP status during the individual station test.

(3) Test both interfaces of the Q series C24 simultaneously in an individual station test. Alternatively, either one of the interfaces can be tested in an individual station loopback test.
In that case, ignore the test results on the interface side for which the test is not performed.

(4) Cable removal and reconnection before and after the individual station loopback test should be performed with the power to the Q series C24 mounting station turned off.

(5) To restart data communication with an external device after an individual station test, check the specifications of the devices used before defining various settings and reconnecting cables.
For the interface that is not used for communication (no cable connection), define the switch settings in GX Developer as follows (for the setting method, see Section 4.5.2).
- Communication protocol setting: 0_H to 7_H
- Transmission control settings and communication rate settings: all set to OFF.

(6) If an error occurs even though the correct settings have been made for the Q series C24 through an individual station test, please consult your nearest dealer or branch office with a description of the error.

4.7.1 ROM/RAM/switch tests

A ROM/RAM/switch test checks the contents of the memory of the Q series C24 and the switch settings set with GX Developer.
Perform a ROM/RAM/switch test with the procedure described below.

(Procedure 1) Communication protocol setting and transmission setting (see Section 4.5.2)

(1) Set the communication protocol setting on the CH2 side to E_H (ROM/RAM/switch test). Set the communication protocol setting on the CH1 side to the number (1 to 8) used for data communication with an external device following the test.

(2) Set the transmission settings for the two interfaces to match the specifications used when communicating data with an external device.

(Procedure 2) Performing ROM/RAM/switch tests

(1) Set the PLC CPU to STOP status.

(2) Restart the PLC CPU station or reset the CPU. The test starts automatically in about one second.

(3) For the Q series C24, the following tests should be performed once.

1) ROM check
Read the ROM data and verify the sum check.

2) RAM check
Write data to RAM, and read and check it.

3) Switch check
Check whether or not each switch is set within the tolerance range and the operation setting in the transmission settings is set to off.

4) Linked operation setting check (perform this test with the operation setting in the transmission settings of CH2 set to on)
Check to see that the communication protocol setting on CH1 is set to 8H and whether the communication rate setting of each channel is within the tolerance range.

＊ A linked operation setting check is performed when values are set as follows:
- Communication protocol setting on the CH1 side : 8H
- Operation setting in the transmission settings on the CH2 side: bit 8 = ON.

(Procedure 3) Checking results of ROM/RAM/switch tests

(1) The test is completed when the NEU LED on CH1 side is lit (approximately 2 seconds).

(2) The test is completed normally when the ERR LED turns off.

(3) The test is completed with error when the ERR LED turns on. Check the error description in one of the following screens.
- The "Monitor others" screen of QSCU (see Section 8.6.9)
- The buffer memory monitor screen of GX Developer (see the GX Developer Manual for the operation method)

＊ When checking errors in the buffer memory monitor screen of GX Developer, monitor the following buffer memory.

Check the error descriptions on the screens by bit-decoding the monitored value (16-bit integer). Each bit corresponds to the following error description.

<table>
<tr><th colspan="4">Buffer memory monitored</th><th colspan="2" rowspan="2">Description when corresponding bit is on</th><th rowspan="2">Corrective action</th></tr>
<tr><th>Address / Bit location</th><th>CH1 side
201H</th><th>CH2 side
202H</th><th>CH1/CH2 side
203H</th></tr>
<tr><td>b0</td><td colspan="2">—</td><td>—</td><td colspan="2">—</td><td rowspan="5">Review setting value
(see Section 4.5.2)</td></tr>
<tr><td>b1</td><td colspan="2">SIO</td><td>—</td><td rowspan="2">When linked operation setting</td><td>Transmission setting error</td></tr>
<tr><td>b2</td><td colspan="2">PRO</td><td>—</td><td>Protocol setting error</td></tr>
<tr><td>b3</td><td colspan="2">P/S</td><td>—</td><td rowspan="2">When independent operation setting</td><td>Transmission setting error</td></tr>
<tr><td>b4</td><td colspan="2">C/N</td><td>—</td><td>Protocol setting error</td></tr>
<tr><td>b5 to b6</td><td colspan="2">—</td><td>—</td><td colspan="2">—</td><td>—</td></tr>
<tr><td>b7</td><td>NEU</td><td>—</td><td></td><td colspan="2">Test completed</td><td>—</td></tr>
<tr><td>b8 to b13</td><td colspan="3">—</td><td colspan="2">—</td><td>—</td></tr>
<tr><td rowspan="2">b14</td><td rowspan="3">—</td><td>CH2 ERR</td><td>—</td><td colspan="2">RAM error</td><td>(＊1)</td></tr>
<tr><td>—</td><td>Setting station number</td><td colspan="2">Out of the setting station number range</td><td>Review setting value
(see Section 4.5.2)</td></tr>
<tr><td>b15</td><td>CH1 ERR</td><td>—</td><td colspan="2">ROM error</td><td>(＊1)</td></tr>
</table>

＊1 Consult your nearest dealer.

(Procedure 4) Ending a ROM/RAM/switch test

(1) Perform the following procedures after checking normal completion/abnormal completion of the test results.
Normal completion : Perform operation (2) to finish tests.
Upon error occurrence : When an error occurs in a switch check or linked operation setting check, set the correct values and test again.
When an error occurs in a ROM or RAM check, check the mounting status of module and test again.
If there is no error in the mounting status of module, consult your nearest dealer or branch office.

(2) Perform the ending procedure for ROM/RAM/switch test

1) Follow the procedure in Section 4.7.2 to perform an individual loopback test operation.
2) Perform the following procedure to end the test and start data communication with an external device.
- Set the switch settings on GX Developer according to the procedure specified in Section 4.5.2.
- Turn off the power to the station on which the Q series C24 is installed and connect the communication cable with an external device.
- Turn on the power to the station on which the Q series C24 is installed.

4.7.2 Individual station loopback test

The individual station loopback test checks the operation of the communication function of the Q series C24.
Follow the procedure below to perform an individual station loopback test.

(Procedure 1) Connecting cable

(1) Connect cables to two interfaces as follows.
- Connect cables to the RS-232 interface within the connector and install it to the interface.
- Connect cables to the RS-422/485 interface on a terminal block.

RS-232 interface (D-Sub 9 pin)

QJ71C24 side (-R2)		Cable connection
Signal name	Pin number	
CD	1	
RD (RXD)	2	
SD (TXD)	3	
ER (DTR)	4	
SG	5	
DR (DSR)	6	
RS (RTS)	7	
CS (CTS)	8	
RI (CI)	9	

RS-422/485 interface

QJ71C24 side		Cable connection
Signal name	Pin number	
SDA		
SDB		
RDA		
RDB		
SG		
FG		
FG		

(Procedure 2) Communication protocol setting and transmission setting (see Section 4.5.2)

(1) Set the communication protocol setting to FH (individual station loopback test) for both interfaces.

(2) Set each transmission setting of the two interfaces according to the transmission specification for data communication with an external device.

(Procedure 3) Performing the individual station loopback test

(1) Set the PLC CPU to STOP status.

(2) Restart the PLC CPU station or reset the CPU. The test starts automatically in about one second.

(3) For the Q series C24, perform the following tests in sequence and repeat them (one test cycle takes approximately one second).
* End testing when all test results become abnormal.
  1) Check communication with the PLC CPU
     Read and check the model type of the PLC CPU.
  2) Check transmission and reception functions of the interface
     Perform communication while changing data.

(4) The LED corresponding to a test item flashes when the test starts.
- The CH1 NEU LEDs flash when checking communication with the PLC CPU.
- The SD and RD LEDs of the interface being tested flash when checking the communication functions of each interface.

(Procedure 4) Checking the results of an individual loopback test

(1) This test is performed repeatedly. When the ERR LED is off, the test is being executed normally.

(2) The test is completed with an error when the ERR LED is lit. Check the error description on one of the following screens. (The ERR LED is lit upon error occurrence, and the test is completed.)
- The "Monitor others" screen of QSCU (see Section 8.6.9)
- The buffer memory monitor screen of GX Developer (see the GX Developer Manual for operation method)

  ∗ When checking for errors in the buffer memory monitor screen of GX Developer, monitor the LED ON status storage area (address CH1: 201H, CH2: 202H).

Check the error descriptions on the screens by bit-decoding the monitored value (16-bit integer). Each bit corresponds to the following error description.

Buffer memory monitored: Address / Bit location	CH1 side 201H	CH2 side 202H	Description when corresponding bit is on	Corrective action
b0 to b3	—		—	—
b4	C/N	—	Error occurrence in the CPU module.	Remove errors occurring in the CPU module.
			Not enough power supply capacity.	Examine the power supply capacity.
			Module is not mounted correctly.	Reinstall the module properly.
			Error occurrence in the base unit, extension cable, CPU module, or the Q series C24.	Check each module and remove the cause of the error. Reconnect the cable correctly. Reinstall the module correctly.
b5 to b13	—		—	—
b14	—	CH2 ERR	CH2 side communication error	Reconnect the cable correctly. Examine the test wiring connection.
b15		CH1 ERR	CH1 side communication error	

(Procedure 5) Ending individual station loopback test

(1) Perform the following procedures after checking normal completion/abnormal completion of the test result.
Normal completion : Perform operation (2) to finish the test.
Upon error occurrence : Remove the cause of the error according to the corrective action specified in the table above, and test again.

(2) Perform the ending procedure for individual station loopback test

1) Follow the procedure in Section 4.7.1 to perform a ROM/RAM/switch test.
2) Perform the following procedure to end the test and start data communication with an external device.
   - Set the switch settings on GX Developer according to the procedure specified in Section 4.5.2.
   - Turn off the power to the station on which the Q series C24 is installed and connect the communication cable with the external device.
   - Turn on the power to the station on which the Q series C24 is installed.

4.8 Loopback Test

A loopback test performs a communication test using the loopback test function of the MC protocol, in order to check the connection between the Q series C24 and an external device, the communication function of each device, and the operation of the communication program of the external device.

(Procedure 1) Connecting the Q series C24 to an external device

Turn off the power to the station on which the Q series C24 is installed and connect a communication cable to an external device to perform data communication using the MC protocol (see Section 4.4).

(Procedure 2) Switch setting with GX Developer

(1) Set the switch settings with GX Developer as shown in Section 4.5 and write the parameters to the PLC CPU in order to perform data communication using the MC protocol.

(2) The following shows an example of the settings when performing a loopback test on the interface on the CH1 side.

- Switch 1: 0544H — Transmission setting — Operation setting : Independent operation
  - Data bit : 7 bit
  - Parity bit : Yes (odd)
  - Stop bit : 1 bit
  - Sum check code : No
  - Write during RUN : Allowed
  - Setting modification : Prohibited
  - Communication rate setting : 9600 bps
- Switch 2: 0001H — Communication protocol setting : MC protocol (format 1)
- Switch 3: 0000H
- Switch 4: 0000H
- Switch 5: 0000H — Station number setting : 0 station

(Procedure 3) Performing a loopback test

(1) Set the PLC CPU to STOP status, and turn the power on or reset the CPU (communication is enabled in about one second).

(2) Create a program for a loopback test on the external device side and send a command message like the one in the example below to the Q series C24.
The commands used are as follows:

- When performing communication test in an A compatible 1C frame: TT command (for an example, see the following page)
- When performing communication test in a QnA compatible frame: 0619 command

* See the Reference Manual when performing communication tests in a QnA compatible frame.

(Procedure 4) Checking loopback test result

(1) The Q series C24 sends a response message to the external device when it receives a loopback test command message.

* The Q series C24 sends the external device the received data as is.

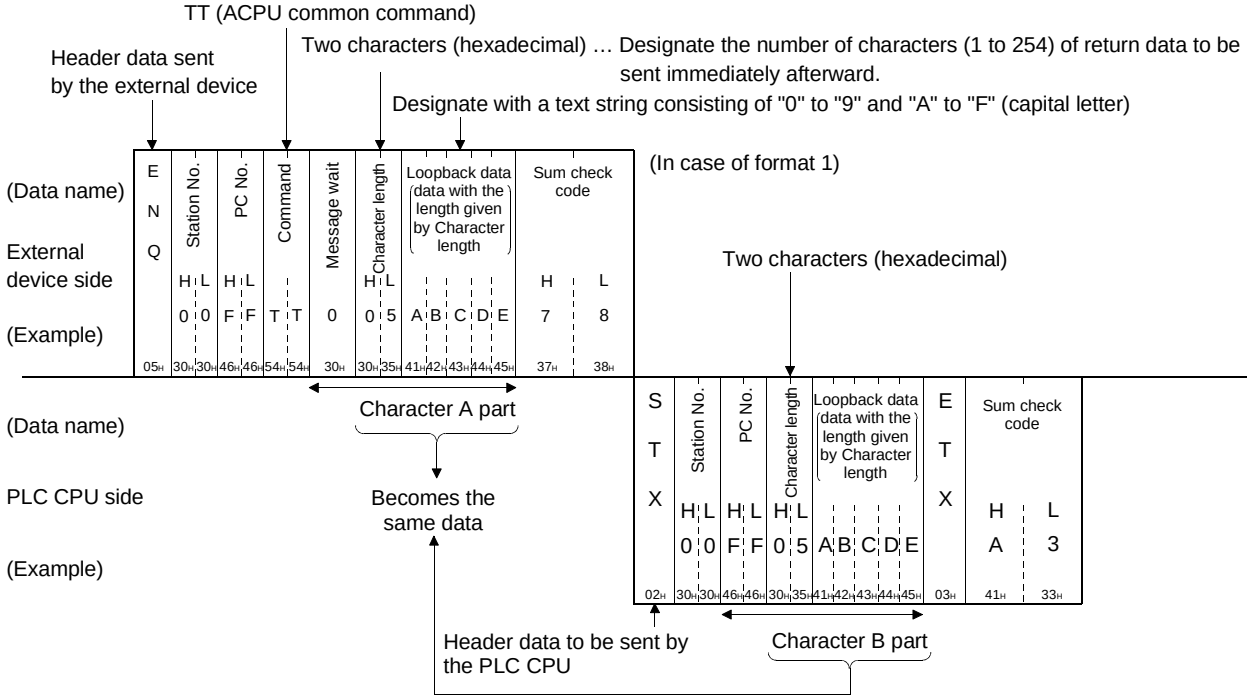
(2) Check on the external device whether the data received from the Q series C24 matches the data sent from the external device.

(Procedure 5) Ending the loopback test

Perform the following procedure according to the function used, and start data communication.

- Set the switch settings with GX Developer according to the procedure specified in Section 4.5.2.
- Turn on the power to the station on which the Q series C24 is installed.

* An example control procedure when the TT command is used in the loopback test mentioned in Procedure 3.
  (Station number: 00, sum check code: Yes)



4.9 Maintenance and Inspection

This section explains the maintenance and inspection and installing and removing of the Q series C24.

4.9.1 Maintenance and inspection

The Q series C24 has no special inspection items other than below.
For items other than listed below, perform inspection according to the inspection items listed in the User's Manual of the PLC CPU module in order to always use the system in the optimal condition.

(the Q series C24 inspection items)

1) Check if the terminal resistors and cables are connected securely.
2) Verify that the module installation screws and the terminal block installation screws are securely tightened.

POINT
Be sure to read through the Safety Precautions in the beginning of this manual regarding the Q series C24 inspection and maintenance.

4.9.2 When mounting/dismounting the module

Please read 4.1, "Handling Precautions" before mounting or dismounting the module, and make sure to pay attention to safety and handle the module properly during the operation.
When replacing the Q series C24 and QCPU, it becomes necessary to register the following data on the Q series C24 again for the module to be replaced.

- Q series C24: System setting data in the flash ROM
- QCPU: PLC parameters (I/O assignment, switch setting, etc.)

The procedure for replacing a module, including re-registration of data, is as follows.

<Operation procedure when replacing the Q series C24>

(Step 1) Read all the system setting data of the Q series C24 using the Read from module function of QSCU.
(Step 2) Save the system setting data read to the specified file using the File Save function of QSCU (*1).
(Step 3) Turn the power supply to the Q series C24 off.
(Step 4) Dismount the cables and the module itself.
(Step 5) Replace the module and start up the module according to "4.2 Settings and Procedures Prior to Operation."
(Step 6) Read the data saved in (Step 2) back into the system and register the system setting data to the flash ROM of the Q series C24 using the Write to module function of QSCU.

<Operation procedure when replacing the QCPU>

(Step 1) Read the PLC parameters with GX Developer from the QCPU and save them.
(Step 2) Replace the QCPU. (See the user's manual for QCPU.)
(Step 3) Register the PLC parameter saved by GX Developer back into the QCPU again.

*1 It is recommended to record and save the system setting parameters not only when replacing the module, but also when changing the system setting parameters using QSCU.

5 DATA COMMUNICATION USING THE MELSEC COMMUNICATION PROTOCOL

This chapter explains an overview of the MELSEC communication protocol (hereinafter abbreviated as the MC protocol). See the following manual for a detailed explanation of the data communication functions that are available when using the MC protocol.
Q Corresponding MELSEC Communication Protocol Reference Manual (SH-080008)

5.1 Data Communication Functions

The MELSEC protocol (MC protocol) is a communication system for the Q series PLCs. Using this protocol, the external devices can read or write device data and programs for the PLC CPUs via the Q series C24 or Q series Ethernet interface module.
Any external devices on which application programs can be installed and which can transmit and receive data in accordance with the MELSEC PLC protocol can communicate with the PLC CPUs using the MC protocol.

5.1.1 Accessing the PLC CPUs using the MC protocol

This section describes the main functions for accessing the PLC CPUs using the MC protocol.
(An overview of the data communication functions using the MC protocol is provided in Section 3.4).
With the exception of the on-demand function described below, the Q series C24 sends and receives data based on commands from the external devices.
Thus, the PLC CPU side does not require sequence programs for data communication.

(1) Data read/write

This function reads and writes data from/to the PLC CPU device memory of the local-station or other station on the MELSECNET/H, MELSECNET/10 as well as the intelligent function module buffer memory.
By reading and writing data, the PLC CPU operation monitoring, data analysis and production management can be performed on the external device side.
Also, production directions can be executed on the external device side.

(2) File read/ write

This function reads and writes files stored in the PLC CPU such as sequence programs and parameter files. By reading and writing files, file management for the QCPU and the QnACPUs of other stations can be performed on the external station side.
Also, execution programs can be changed (replaced) from the external device side.

(3) Remote control of the PLC CPU

This function executes remote RUN/STOP/PAUSE/latch clear/reset operations.
Remote operations of the PLC CPU can be performed from the external device side using the PLC CPU remote control function.

(4) Monitoring the PLC CPU

This function monitors the operating status of the PLC CPU and the data in the device memory.
The PLC CPU status and the device memory data can be sent to the external device at fixed intervals, when an error occurs in the machine equipment, or when certain conditions are satisfied.
This function reduces the data read processing load on the external device side.

(5) Sending data from the PLC CPU to the external device

A function for requesting data transmission from the PLC CPU to the external device is called the on-demand function.
Urgent data that must be forwarded to the external device can be sent as on-demand data to the external device by starting up from the PLC CPU.

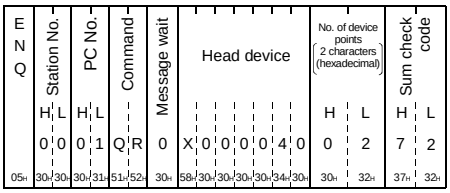
5.1.2 Message format and control procedure for data communication

The data communication functions using the MC protocol correspond to the data communication functions using the dedicated protocol for the conventional products listed below.

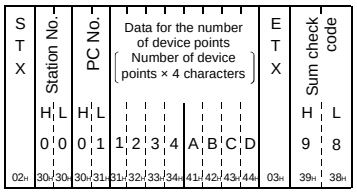
- A series computer link module
- QnA series serial communication module

Therefore, the message format and control procedure are the same as when accessing the PLC using these conventional modules.
The external device side can access the Q series PLC with a program used for accessing the PLC via a conventional module.

(Example)



(Command message for A compatible 1C frame)



(Response for A compatible 1C frame)

POINT

The following manual is available for performing data communication using the MC protocol.
MELSEC Communication Protocol Reference Manual (sold separately)

5.1.3 PLC CPU setting for performing data communication

Data communication using the MC protocol is achieved by performing the GX Developer settings indicated below on a PC, performing the system settings by the QSCU, and registering the settings to the PLC.

(1) Settings using the GX Developer (Required)

Perform the I/O assignments and switch settings indicated in Section 4.5 and write the parameters to the PLC CPU where the Q series C24 is installed.

(2) System settings using the QSCU

When it is necessary to change the default values registered in the Q series C24, perform the settings as indicated in Chapter 8 and register these to the flash ROM in the Q series C24.

- MC protocol system setting
- Transmission control and others system setting

POINT

To write from the external device to the intelligent function module installed in the MELSECNET/H, MELSECNET/10 remote I/O station during communication using the MC protocol, set the "Write allow/prohibit during PLC CPU RUN" in the GX Developer to enable. (The remote I/O station is always in RUN status. RUN and STOP cannot be switched.)

5.1.4 Support for Multiple PLC systems

When the external device accesses a QCPU in a multiple PLC system, it is possible to access either the control PLC or the non-control PLCs; the target QCPU should be specified in the "requested module I/O number" in the QnA compatible 4C frame for the MC protocol.

See Section 2.10 of the Reference Manual for the details hereof.

See Section 2.5 of this manual for an explanation of the system configuration.

(Example)

	ASCII code	Frame ID No.	Station No.	Network No.	PC No.	Requested module I/O No.	Requested module station No.	Self-station No.	Command	Sub command	Device code	Head device	Number of device points	Sum check code
		H L	H L	H L	H L	H — — L	H L	H L	H — — L	H — — L		H — — — — L	H — — L	H L
		F 8	0 5	0 7	0 7	0 3 E 0	0 0	0 0	0 4 0 1	0 0 0 1	X *	0 0 0 0 4 0	0 0 5	3 6
05H	35H	46H 38H	30H 35H	30H 37H	30H 37H	30H 33H 45H 30H	30H 30H	30H 30H	30H 34H 30H 31H	30H 30H 30H 31H	58H 2AH	30H 30H 30H 30H 34H 30H	30H 30H 30H 35H	33H 36H

(Command massage of the QnA compatible 4C frame format 1)

REMARK

- When using the Q series C24 in a multiple PLC system, it is necessary to specify the QCPU that controls the Q series C24 (hereinafter referred to as the control PLC) using GX Developer (SW6D5C-GPPW-E).
- It is also possible to mount a Q series C24 of function version A in a multiple PLC system. In this case, it is only possible to access the control PLC (PLC No.1).
- It is only possible to access the control PLC if data is communicated by means of frames other than the QnA compatible 4C frame.

5.1.5 Support for the QCPU remote password function

This section explains an overview of the remote password function when a remote password is set for the Q series C24 mounted to a QCPU.
See Chapter 3 of the User's Manual (Application) for a detailed explanation.

(1) Checking remote passwords

If the following items are set to the QCPU using GX Developer (SW6D5C-GPPW-E), the Q series C24 performs a remote password check whenever an external device accesses the PLC using the modem function of the Q series C24.

(a) Setting by GX Developer (SW6D5C-GPPW-E)

- When the remote password is set on the QCPU with the Q series C24.
- When the Q series C24 is set to be subject to the remote password check.

(b) Access in which the remote password is checked

The remote password is checked when the following access is attempted. Access attempts to all PLCs of the local station (the local station with the Q series C24 and other stations accessed via the local station) are subject to the remote password checking.

(Access function to the PLC in which the remote password is checked)

- Data communication using the MC protocol
- Access to the PLC using GX Developer (SW6D5C-GPPW-E)

* The remote password is not checked in data communication using the non procedure/bidirectional protocols.

(c) Remote password to be checked

The check is performed against the remote password set to the local station QCPU with the Q series C24.

* Access to the specified station is allowed if the remote password specified by the user and the remote password set to the QCPU match when accessing.

(2) Data communication procedure

1) Initialize the modem.
2) Connect the line from the external device.
3) Unlock (cancel) the remote password of the QCPU belonging to the station with the Q series C24 mounted from the external device via the dedicated command for communication using the MC protocol.
4) Initiate the data communication between the external device and PLC using the MC protocol.
5) Disconnect the modem line from the external device side when completing the data communication using the MC protocol.
   The remote password is automatically locked when the modem is disconnected.

REMARK

The remote password should be set to a QCPU using GX Developer (SW6D5C-GPPW-E) in order to use the remote password function of the QCPU.

- Unlocking the remote password is possible only for the QCPU of the local station with the Q series C24.
  It is impossible to unlock the remote password for the QCPU of other stations.
  See Section 3.18 of the Reference Manual for the command for unlocking the remote password.
- When accessing the PLC using GX Developer (SW6D5C-GPPW-E), the remote password should be unlocked when starting the online operation.

(3) Q series C24 setting and monitoring function when using the QCPU remote password function

(a) Modem function system setting by QSCU

1) Remote password mismatch notification count designation
   Designate the number of times before notification when a remote password disagreement occurs at the unlock processing by the user/external device after the line is connected.
   The Q series C24 automatically disconnects the line if more remote password disagreements occur than the number of times designated by this value.

2) Remote password mismatch notification accumulated count designation
   Designate the number of times before notification when remote password disagreements occur at the unlock processing by the user/external device after the startup of the Q series C24.
   The error signal on the CHn side (XE, XF) and the ERR LED turn on if remote password disagreements occur more than the number of times designated by this value (the line is not disconnected).
   ✻ The user can clear the cumulative value counted by the Q series C24 at an occurrence of remote password disagreement using either one of the methods below:
   - Set the cumulative number of abnormal completions of unlock processing to "0" in the modem function monitor/test screen of QSCU.
   - Write "0" to the storage area in the buffer memory corresponding to the Accumulated count of abnormal completions of unlock processing (address: 8756 ($22FC_H$)).

(b) Modem function monitor/test by QSCU

It is possible to monitor the setting values for the remote password and the number of occurrences up to the present, such as the designation of the number of times before notifying an unmatched remote password and the current number of occurrences.

* It is possible to set each monitor value to "0."

Monitored items in the “modem function monitor/test” screen	Buffer memory address
Remote password mismatch notification count designation	8204 (200C$_H$)
Remote password mismatch notification accumulated count designation	8205 (200D$_H$)
Accumulated count of unlock process normal completion	8755 (22FB$_H$)
Accumulated count of unlock process abnormal completion	8756 (22FC$_H$)
Accumulated count of lock process based on circuit disconnection	8759 (22FF$_H$)

5.2 Utilizing the MX Component and MX Links

If the external device to access to the PLC is a PC running one of the basic operation systems below, it is possible to create a communication program for the external device without considering the detailed MC protocol (transmission/reception procedures) using one of the following separately sold communication support tools.

(Supported basic operation systems)

- Microsoft® Windows® 95 operating system
- Microsoft® Windows® 98 operating system
- Microsoft® Windows NT® Workstation4.0 operating system

(Separately sold communication support tools)

- MX Component (SW0D5C-ACT-E, hereinafter abbreviated as ACT)
- MX Links (SW3D5F-CSKP-E and later, hereinafter abbreviated as CSKP)

The functions of the CSKP communication support tool are listed below. See the operating manual and programming manual for each communication support tool for the details.

POINT

(1) For details on accessing PLCs of other stations in the network system, see the corresponding system manual.

(2) The PLC CPUs on Ethernet can be accessed via the MELSECNET/H, MELSECNET/10 using the Q series Ethernet interface module MELSECNET/H, MELSECNET/10 relay communication functions.
For details, see Chapter 4, "Communicating by Relaying via the MELSECNET/H, MELSECNET/10" in the Q Corresponding Ethernet Interface Module User's Manual (Application).

The following lists the CSKP functions:

Function	Description
MELSEC data link utility	
Computer link utility	Performs settings for communicating via a serial communication line. (Uses the serial communication module/computer link module)
Ethernet utility	Performs settings for communicating via the Ethernet network system.
CPU COM utility	Performs settings for directly connecting the PLC CPU and the PC to perform communication.
CPU USB utility	Performs settings for connecting the CPU directly to the PC to perform USB communication.
MELSECNET/10 utility	Performs settings for communicating via the MELSECNET/10 network system. (This is a shared utility with the board side package.)
CC-Link utility	Performs settings for communicating via the CC-Link system. (This is a shared utility with the board side package.)
CC-Link G4 utility	Performs settings for communicating via the CC-Link G4 module.
Other utility software	
Shared device utility	Performs settings for using the EM and ED.
Shared device server utility	Performs refresh settings for the device between PCs or between the PC and PLC.
Ladder logic test utility	Performs settings when the logic test function (LLT) is used.
Device monitor utility	Monitors the status of each device via the network.
Error viewer	Displays the error history.
MELSEC data link library (functions)	
mdOpen	Opens a communication line.
mdClose	Closes a communication line.
mdSend	Writes data to device in batch mode.
	Sends data (SEND function).
mdReceive	Reads data from device in batch mode.
	Receives data (RECV function).
mdRandW	Writes data to device in random mode.
mdRandR	Reads data from device in random mode.
mdDevSet	Sets a bit device.
mdDevRst	Resets a bit device.
mdTypeRead	Reads the PLC CPU type.
mdControl	Remote RUN/STOP/PAUSE
mdInit	Refreshes data in the MELSEC data link library.
mdBdRst	Resets own board.
mdBdModSet	Sets the mode of own board.
mdBdModRead	Reads the mode of own board.
mdBdLedRead	Reads the LED information of own board.
mdBdSwRead	Reads the switch status of own board.
mdBdVerRead	Reads the version information of own board.

6 DATA COMMUNICATION USING THE NON PROCEDURE PROTOCOL

Data communication using the non procedure protocol is a function for sending and receiving data between a PLC CPU and an external device using the message format and transmission control procedure specified by the user.
Data can be transferred using the non procedure protocol when it is necessary to perform data communication using the protocol for external devices such as a measuring instrument and a bar code reader. In that case, transmission/receive data processing can be simplified by using the communication functions with the user frames described in the User's Manual (Application).

This chapter explains the basic transmission and reception methods when performing data communication using the non procedure protocol.
Follow the procedure described in this chapter to create sequence programs for sending and receiving data for the PLC CPU.
For details on the additional functions listed below for data communication using the non procedure protocol, see the separate User's Manuals (Application).

- Sending/receiving data using user frames (See Chapter 11, Application)
- Monitoring the PLC CPU (automatic information function) (See Chapter 2, Application)
- Switching modes from the PLC CPU (See Chapter 15, Application)
- Reading received data using interrupt programs (See Chapter 4, Application)
- Sending/receiving data using transparent code designation (See Chapter 12, Application)
- Sending/receiving data using ASCII data (ASCII-BIN conversion) (See Chapter 13, Application)
- Controlling half-duplex communication (See Chapter 8, Application)

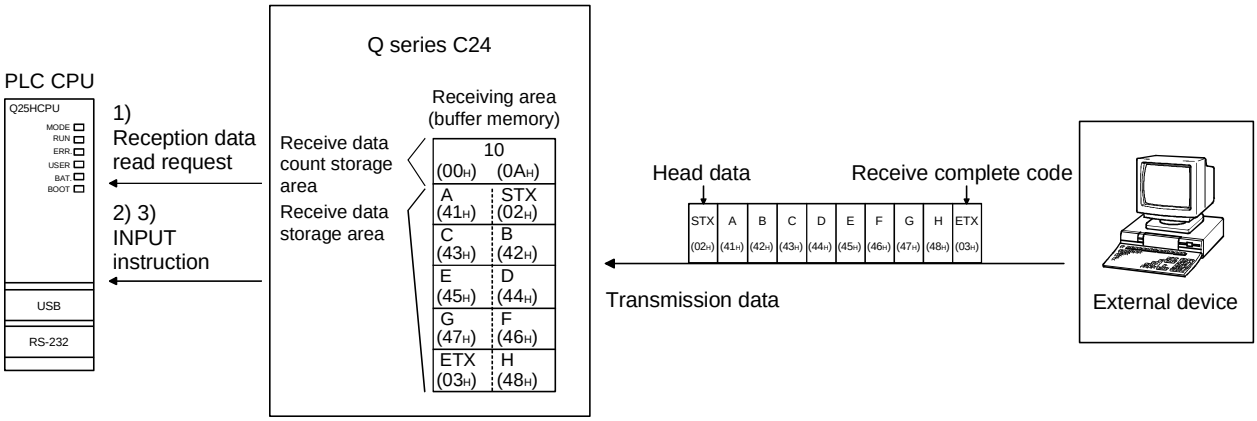
6 - 1

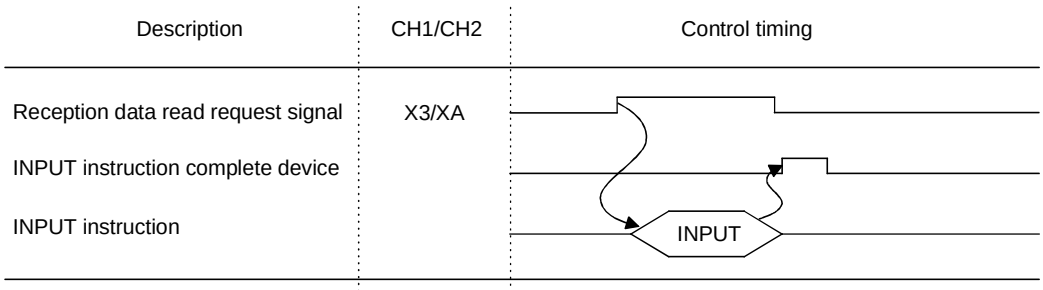
6.1 Data Reception from the External Device

This section explains data reception from the external device.
There are two methods for receiving data: the "reception via receive complete code" for receiving variable length messages, and the "reception via received data count" for receiving fixed length messages. The receive complete code and received data count used for data reception can be changed to any setting values chosen by the user using QSCU.

6.1.1 Receiving methods

The following shows the methods for receiving data in any format using the non-procedure protocol.
There are two methods for receiving data: the "reception via receive complete code" for receiving variable length messages, and the "reception via received data count" for receiving fixed length messages. The receive complete code and received data count used for data reception can be changed to any setting values chosen by the user using QSCU.





1) When data is received from the external device using either "reception via receive complete code" or "reception via received data count" method, the reception data read request signal turns ON.
2) Control data is stored in the device designated with the INPUT instruction.
3) When the INPUT instruction is executed, receive data is read from the reception area of the buffer memory.

(1) Data reception by receive complete code (for variable length reception)

(a) This method is used to send data by adding the receive complete code set in the Q series C24 at the complete of the message to be sent from the external device.

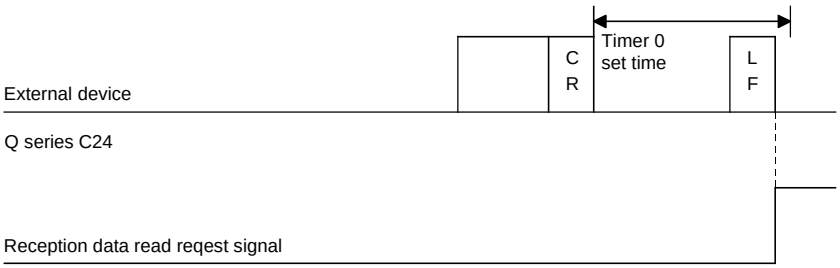
(b) When the Q series C24 receives the receive complete code data preset in QSCU by the user, it sends a receive data read request to the sequence program.
The read request from the Q series C24 allows the sequence program to read the receive data up to the receive complete code received from the external device.

(c) The receive complete code can be changed to match the specifications of the external device. An arbitrary 1-character (1-byte) code within the 00_H to FF_H range can be designated.

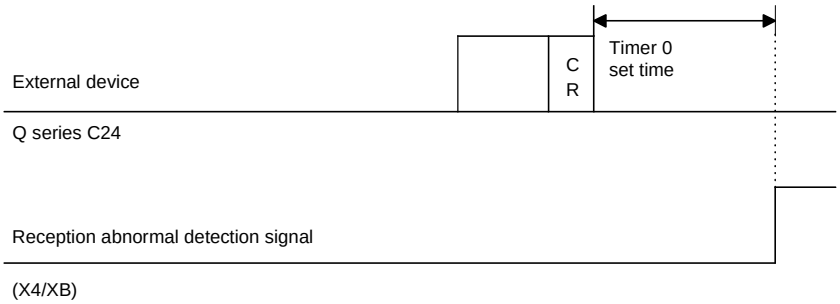
(d) The Q series C24 issues a receive data read request to the PLC CPU as follows, according to the set value of the receive end code.

1) When receive complete code not changed (Default value: $0D0A_H$)
(CR+LF is added to the end of the message and sent from the external device.)

• If LF is received within the time set in the no-reception monitoring time (timer 0) after CR is received, the Q series C24 stores the receive data up to CR+LF to the buffer memory receive data storage area and turns on the read request signal to the PLC CPU.

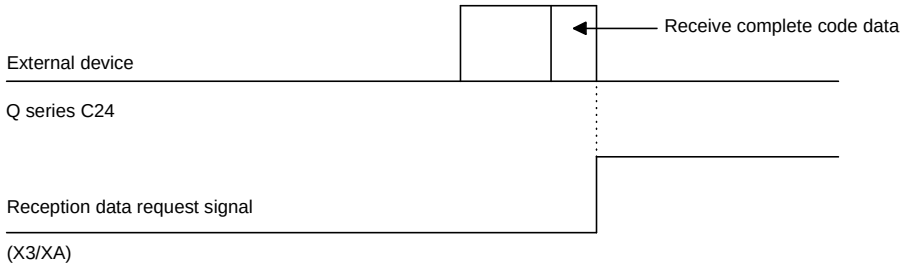


• If the next data (LF, etc.) is not received within the time set in the no-reception monitoring time (timer 0) after CR is received, the Q series C24 stores the receive data up to CR to the buffer memory receive data storage area and turns on the reception abnormal detection signal to the PLC CPU.



* If the following data (excluding LF) is received within the time set in the no-reception monitoring time (timer 0) after receiving a CR, the CR is treated as 1 byte of data included in the message. (In this case, CR is not treated as data belonging to the receive complete code.)

2) When the receive complete code is changed and an arbitrary code is designated (00□□H designated)
(User defined receive complete code data is added to the end of the message and sent from the external device).
When the Q series C24 receives the receive complete code data changed by the user, it stores the receive data up to the receive complete code to the buffer memory receive area and turned on the read request signal to the PLC CPU.



3) When receive complete code not designated (FFFFH designated)
Reading by received data count is enabled.
See (2) for a description of reading by received data count.

(2) Reception by received data count (For fixed length reception)

(a) This method is used to receive messages of the same length (size) from the external device every time.

(b) When the Q series C24 receives data of the received data count preset in QCSU by the user, it sends a reception data read request to the sequence program.
When the sequence program receives the read request from the Q series C24, it reads data up to the received data count received from the external device.

(c) The received data count default value is set to 511 (words). However, it can be changed within the size of the receive data storage area depending on the data contents exchanged with the external device.

POINT

(1) When the receive complete code and received data count are set to QSCU, both become valid.
In this case, if the Q series C24 receives the receive complete code before data corresponding to the received data count, it outputs (X3/XA: ON) a reception read request signal to the sequence program.

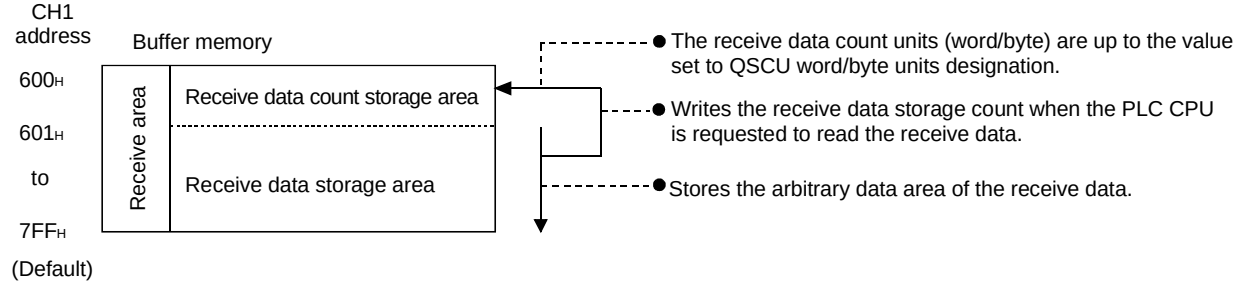
(2) For details on how to change the receive complete code and received data count, see Section 8.4.7.

6.1.2 The receive area and the received data list

The following shows the list of the receive area and the receive data for performing data reception using the non procedure protocol.

(1) Receive area

The receive area is a memory area for storing the data received from the external device and the receive data count in order to read the receive data for the PLC CPU. By default, the receive area is assigned to addresses 600H to 7FFH (CH1 side) and A00H to BFFH (CH2 side).



POINT

(1) The position and size of the receive area in the buffer memory can be changed with the QSCU in accordance with the specifications of the external device and the receive data length. (See Section 8.4.7.)

(a) When changing the position and size of the receive area in the buffer memory with QSCU, specify as follows:

1) Receive buffer memory head address designation
Designate the starting address for the area to be used as the receive area in the user-definable area of the buffer memory.
2) Receive buffer memory length designation
Designate by address the length of the area to be used as the receive area in the user-definable area of the buffer memory.

(b) If the following functions are also used when the position and size of the receive area in the buffer memory are changed, make sure that the addresses of the receive area do not overlap with those for the buffer memory that stores the transmission and reception data to be used by these functions.

1) MC protocol buffer memory read/write function
2) MC protocol on-demand function
3) Non procedure protocol transmission/receive function
4) Bidirectional protocol transmission/receive function

(2) When sending data from the external device to the Q series C24, one of the following two adjustments should be made so that the relationship shown below is maintained.

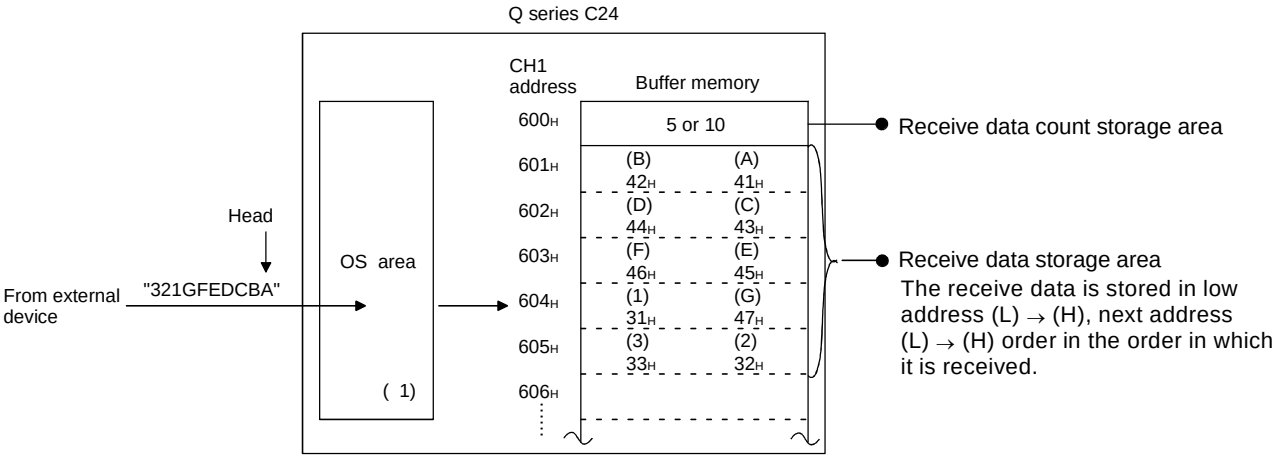
1) Reduce the transmission data size.
2) Increase the receive area.
Receive data storage area ≧ Size of data sent from the external device

(2) Receive data list

The following describes the data list when data received from an external device is stored to the receive area.

1) The receive message is stored to the Q series C24 buffer memory (receive data storage area).
2) The data is stored to the receive data storage area in low address (L) → (H), next address (L) → (H) order.
   ＊ Under the following conditions, when the receive data count is an odd byte, 00H is stored in the upper byte of the final data storage position:
   - When the unit for the received data count is designated in bytes.
   - When data reception is performed using the receive complete code.

(Example) When receive arbitrary data area "ABCDEFG123" was stored (The receive area is the default value.)



＊1 The OS area of the Q series C24 shown in the above diagram is the memory (2304 bytes) that temporarily stores the data to be received while a request for the reading of the receive data is being made to the PLC CPU. (The user cannot read the receive data in the OS area).
When the sequence program finishes reading the receive data in the buffer memory in response to the read request, the receive data in the OS area, and any succeeding receive data, is stored successively in the receive area of the buffer memory when the next read request is issued.
Also, when the OS area's free space, which stores the receive data, is reduced to 64 bytes or less, a request to discontinue data reception from the external device is issued by the following transmission control (the RS signal does not turn OFF):

- When DTR control is set, the DTR signal turns OFF.
- When DC1/DC3 transmission control is set, DC3 is sent.

When there is no more free space in the OS area to store receive data, an SIO error occurs and the SIO information bit in the communication error information storage area (address: 201H/202H) in the buffer memory turns ON. In that case, succeeding receive data is discarded until a free space becomes available in the OS area.

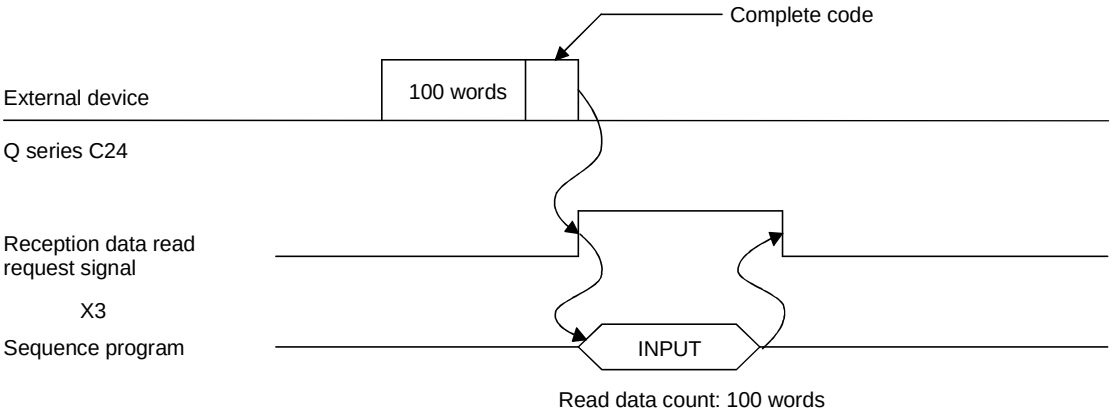
＊ For more details on the transmission control, see Chapter 7 of the User's Manual (Application).

REMARK

(1) Data reception when the receive data storage area is larger than the receive data length

The following control is performed.

(Example) When the receive area for the CH1 side interface is located at addresses 600H to 7FFH (default values) and data of 511 words or less is received by the CH1 side interface.

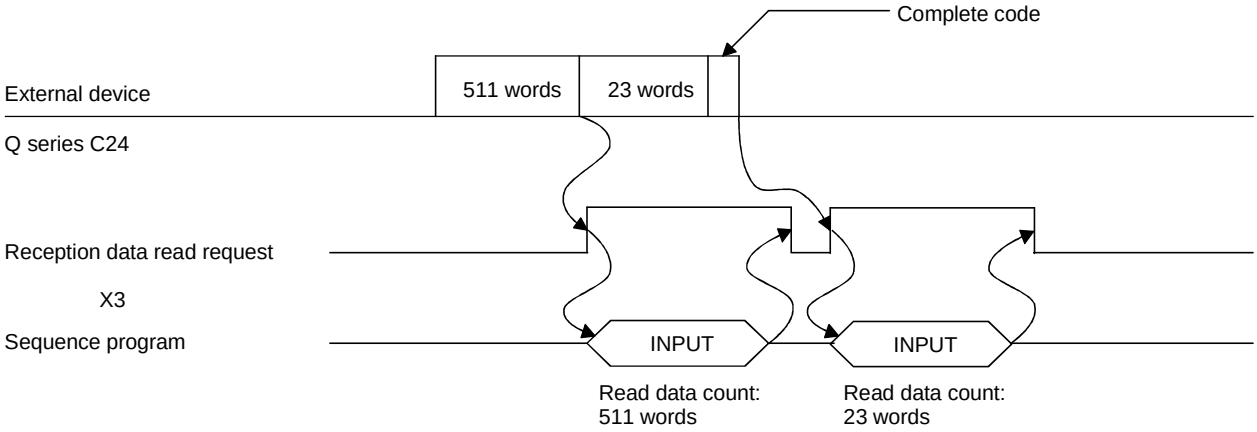


(2) Data reception when the receive data storage area is smaller than the receive data length

Since the following control is performed, data link processing is required in the sequence program.

1) Reception using the complete code

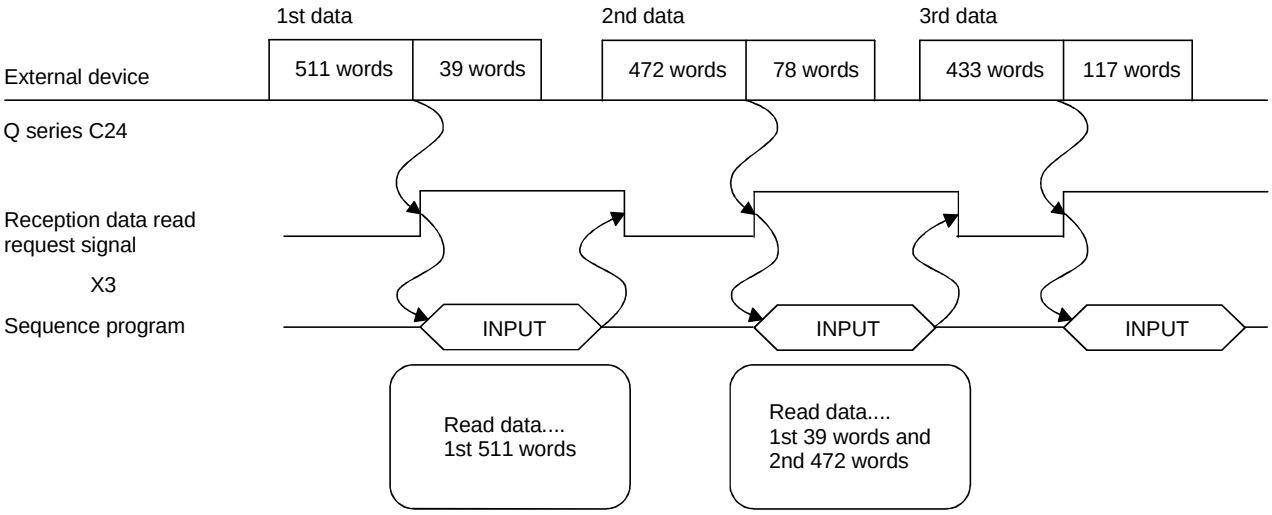
(Example) When the receive area for the CH1 side interface is located at addresses 600H to 7FFH (default values), and data of 534 words is received by the CH1 side interface.



2) Reception by received data count
When the received data count is set larger than the receive data storage area, the receive buffer memory length (default: 512 words) -1 set in buffer memory addresses A7H/147H is processed as the received data count.

(Receive data storage area) > (Data length received from external device)

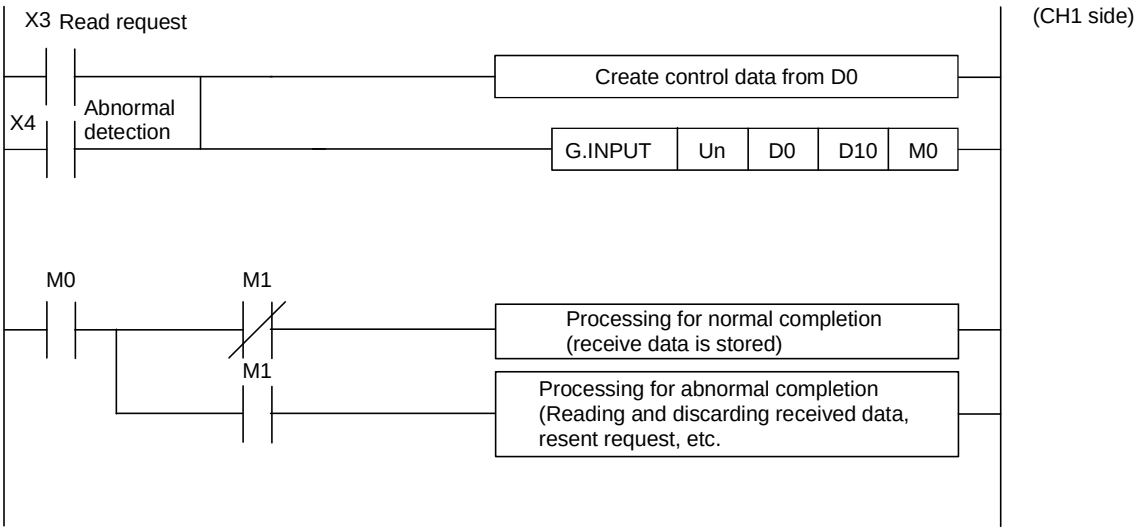
(Example) When 550 words of data is received through the CH1 interface in three parts when the CH1 interface receive area consists of addresses 600H to 7FFH (default value)



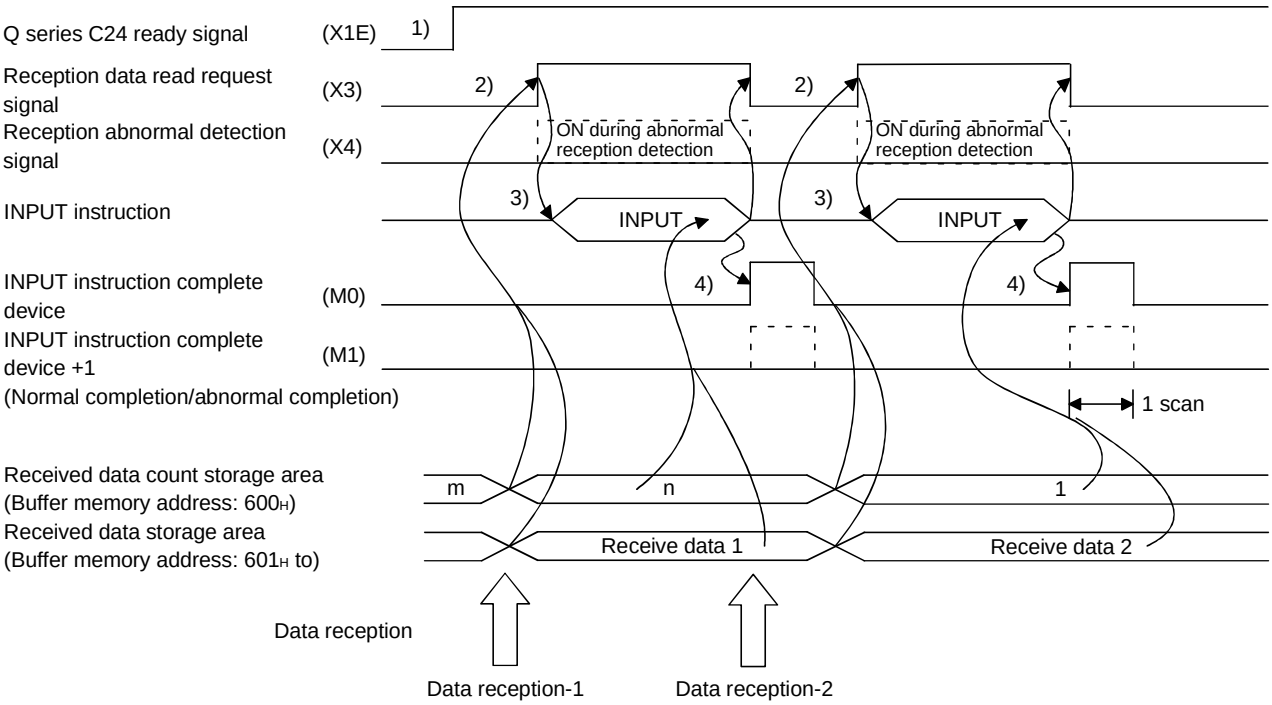
6 - 9

6.1.3 Sequence program for data reception

This section explains the sequence program for data reception.
For details on the INPUT instruction for data reception, see Chapter 9.



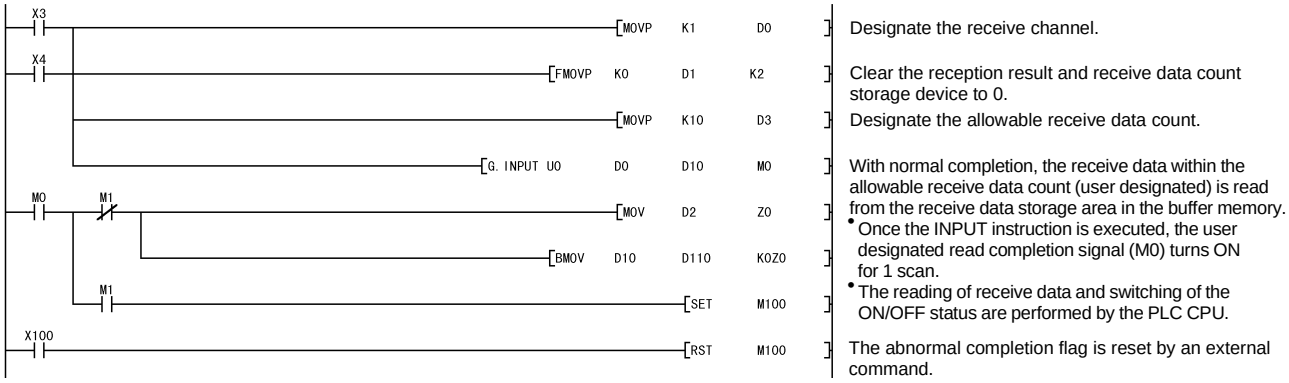
(CH1 side)

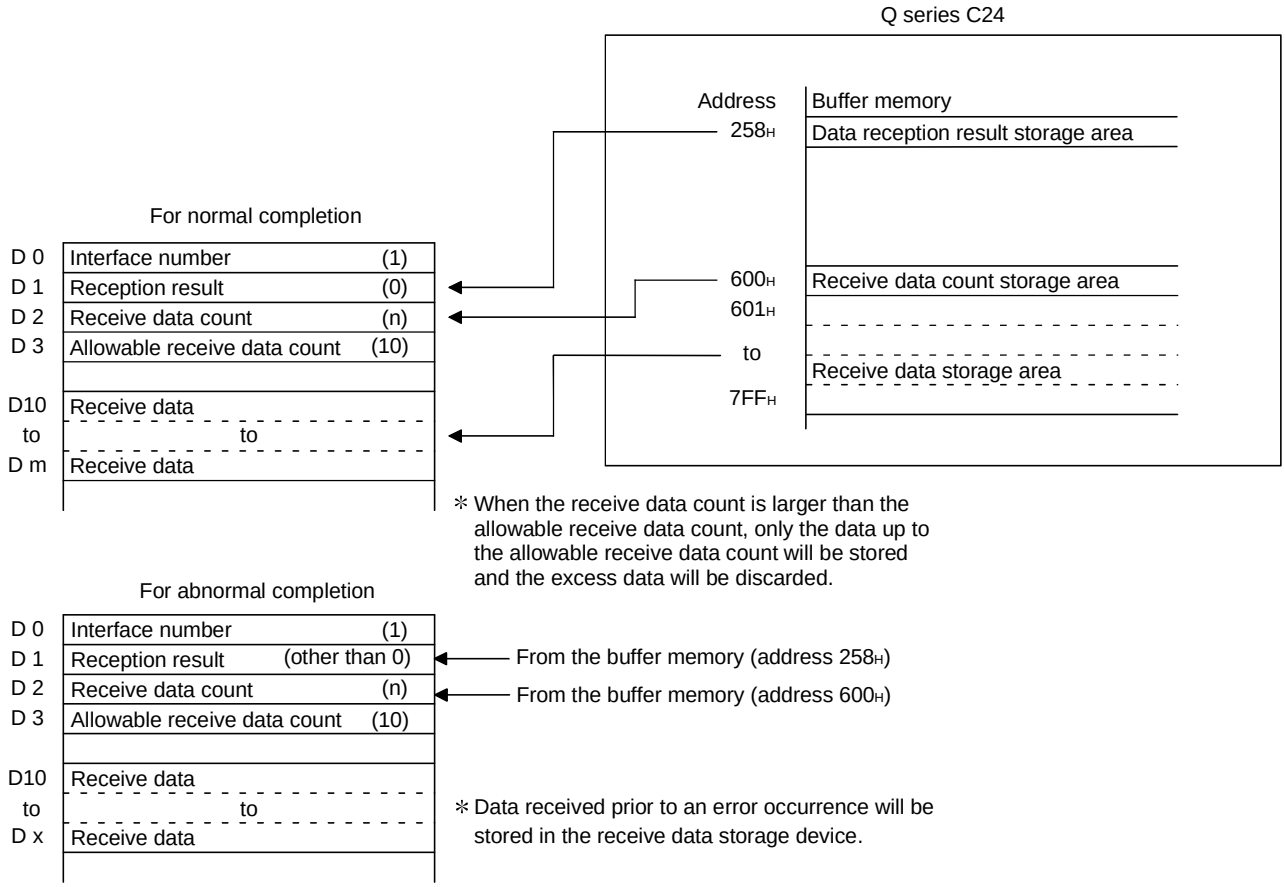


1) Start the self-station PLC.
   The values specified with GX Developer are stored in the Q series C24.
2) When the amount of data specified by the received data count or data containing the receive complete code is received from the external device, the reception data read request signal turns ON.
3) After the control data for the INPUT instruction is stored in the device, the sequence program executes the INPUT instruction and reads the receive data.

4) The device completing the INPUT instruction turns ON when the reading of receive data is completed.
When the complete device + 1 (abnormal completion signal) turns ON, the error code is stored in the control data completion status (S1 + 1).

(Program example)
When the Q series C24 I/O signals are from X/Y00 to X/Y1F:





POINT

(1) Receive data can also be read using interrupt programs.
For more details on reading receive data with interrupt programs, see Chapter 4 of the User's Manual (Application).
Note that if the reading of data received from the same interface is to be performed, it is not possible to combine the reading of data received by the main program and reading of data received by the interrupt program.
Accordingly, use one or the other of the above programs to read the data received.

(2) The SPBUSY instruction is used to read the execution status when using a dedicated instruction. (See Chapter 9.)

(3) More than one INPUT instruction cannot be executed simultaneously.
Execute the next INPUT instruction only after the execution of the first INPUT instruction is completed.

(4) When the communication data count is set in word units, and if the received data count is an odd byte when requesting the reading of received data to the PLC CPU, the receive data count is processed as follows:
Receive data count = Receive data byte count/2 ⋯ Fractions following the decimal point are rounded up
Also, 00H is stored in the higher byte of the final data storage position in the receive area where receive data is stored.

6.1.4 Receive data clear

For the data receiving with the non procedure protocol, when the error occurs in the data transfer to the Q series C24 by the trouble of the external device, the data received up to that point can be cleared.
The reception data can be cleared using the following methods:

1) Clear the reception data by the dedicated instruction "CSET."
2) Write to/read from the reception data clear request area (address A8H/148H). (FROM/TO instruction)
3) Clear the reception data by QSCU (see Section 8.7).

(1) Receive data clear processing

The Q series C24 performs the following procession when the receive data clear is performed.

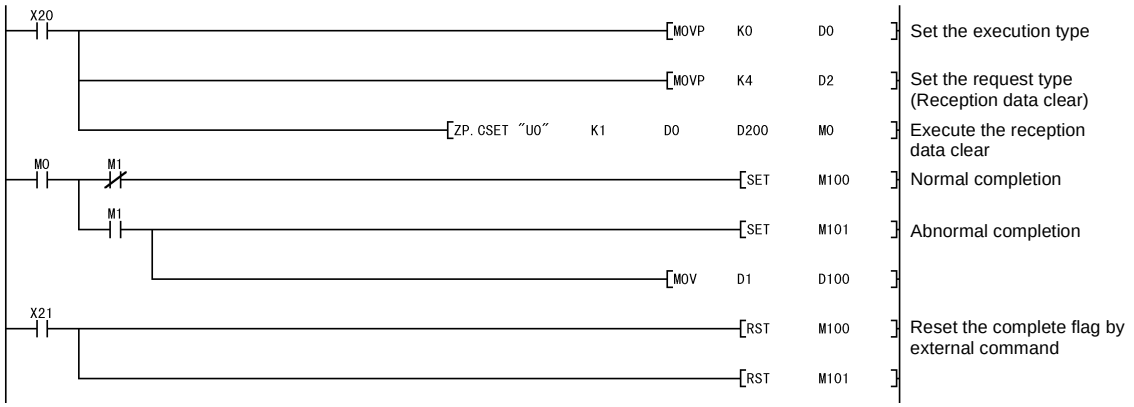
- The data received up to that point can be ignored.
- The receive data count up to that point is "0".
  (The receive area in the buffer memory is not initialized).
- Set to the status prior to the start of data reception.

(2) Procedure for clearing the reception data by the dedicated instruction "CSET"

This instruction clears the reception data up to the present without interrupting the data transmission processing.
(Procedure for clearing) ··· In case of the CH1 side interface

1) Execute the CSET instruction
   If the CSET instruction is executed while the read request (X03/X0A) or reception abnormal detection signal (X04/X0B) is turned on, the CSET instruction is kept waiting until the signal is turned off.
2) The reception data clear processing is executed at the OS area of the Q series C24 (see Section 6.1.2).

The following is a program example of clearing the reception data by the dedicated instruction "CSET."



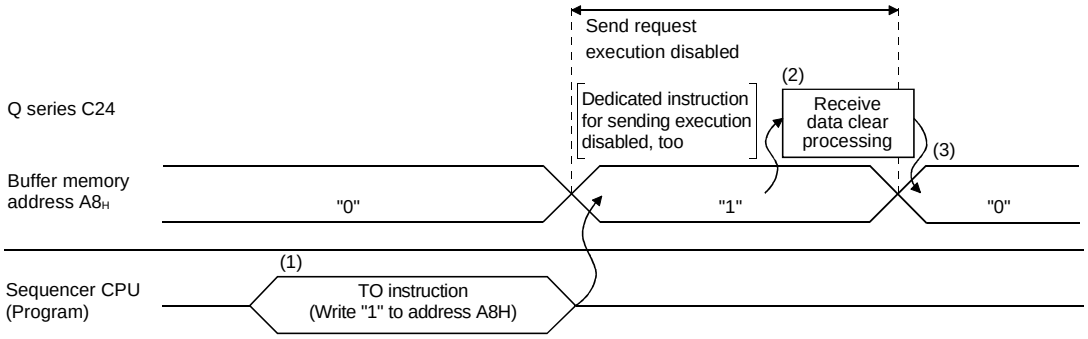
(3) Receive data clear procedure using FROM/TO instruction

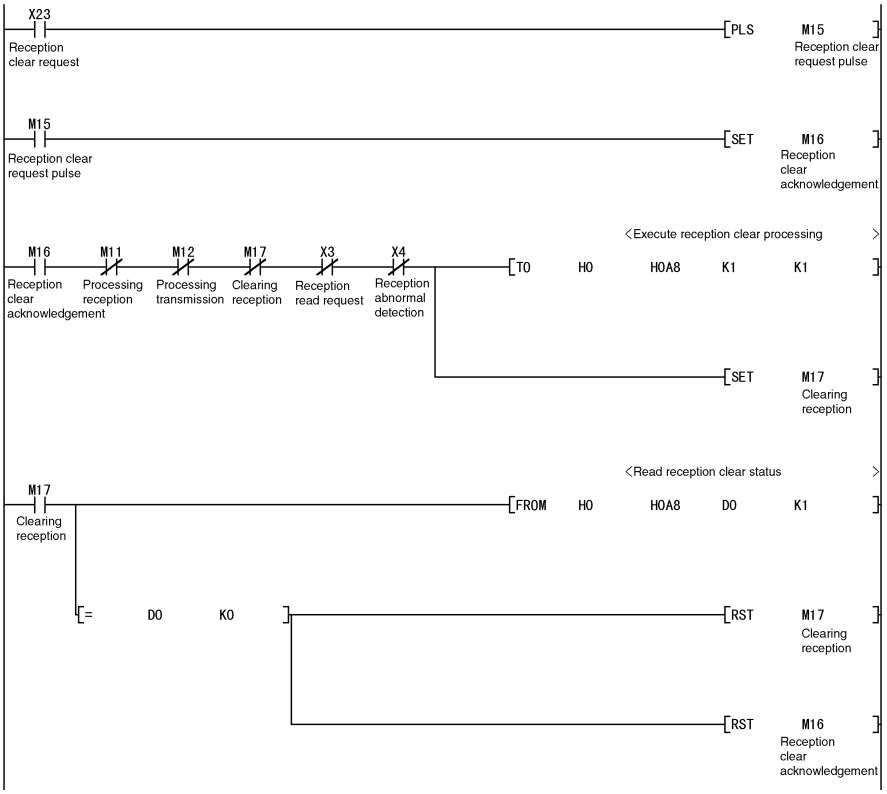
Write and read the buffer memory receive data clear request area (addresses A8H/148H) using the procedure described below.
Before resuming data transmission from the external device, clear buffer memory addresses A8H/148H to [0].
(Depending on the data communications system, the PLC CPU may have to inform the external device that data transmission can be resumed.)
(Clear procedure) ··· CH1 interface

1) When all the receive processing, send processing and receive data clear processing are not performed, writing [1] to buffer memory address A8H with the sequence program TO instruction.
2) The Q series C24 clears the OS area (see Section 6.1.2 ＊1) receive data.
3) When clearing of the receive data is complete, the Q series C24 changes the [1] written to buffer memory address A8H to [0].

The following page shows an example of a program to clear receive data with the FROM/TO instruction.
Create a program that contains the contacts (user flags, etc.) indicating the following statuses in the TO instruction.

- Contact when the CHn reception data read request signal (X3/XA) is OFF
- Contact when the CHn reception abnormal detection signal (X4/XB) is OFF
- Contact indicating that send and receive processes are not currently being performed
- Contact indicating that reception data clear processing is not currently being performed





REMARK

(1) When transmitting data from the Q series C24 to an external device for the dedicated instruction execution, do not issue the receive data clear request described above.
If a receive data clear request is issued while data is being transmitted to an external device, the Q series C24 will terminate data transmission and ends the dedicated transmission instruction abnormally. (The transmission complete signal does not turn ON). When a reception data clear request is executed while data is being received, the data received prior to the request will be cleared.

(2) When resuming transmission after clearing the received data, execute the OUTPUT instruction after the value of the receive data clear request area (address: A8H/148H) of the above buffer memory is changed from "1" to "0."

6.1.5 How to detect reception errors

This section explains how to detect errors that may occur when receiving data from the external device.

The following items are considered as the primary causes of errors that may occur during data reception.

Cause of reception error	Reference section	
A transmission error occurred due to noise.	—	
A timeout for the no-reception monitoring (timer 0) occurred.	User's Manual (Application)	Chapter 6
Received data that could not be converted using the ASCII-BIN conversion.		Chapter 13
Received data larger than the size that could be stored in the OS area of the Q series C24.	Section 6.1.2	

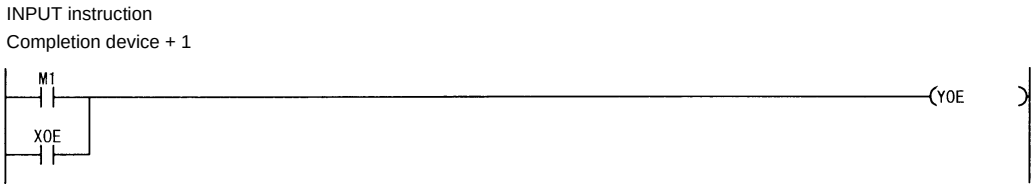
(1) Confirmation using the sequence program

1) The following device and input signals turn ON.
   - INPUT instruction complete device + 1
   - Reception abnormal detection signal (X4/XB)
   - ERR LED ON signal (XE/XF)
2) The reception error code can be checked using the INPUT instruction control data ((S1) + 1).
   Or, it can be checked by reading the data reception result storage area in the buffer memory (addresses 258H/268H).
   For details on how to check the error code contents and take corrective actions, see Chapter 10.

(b) How to turn off the ERR LED and clear the error code (see Section 10.1.2.)

1) To turn off only the ERR LED, write "1" to the LED OFF request area (addresses 0H/1H) in the buffer memory.
2) To turn off the ERR LED and clear the error code, turn ON the ERR LED OFF request output signal (YE/YF).

(Example) To perform the ERR LED OFF and the error code clear on the CH1 side



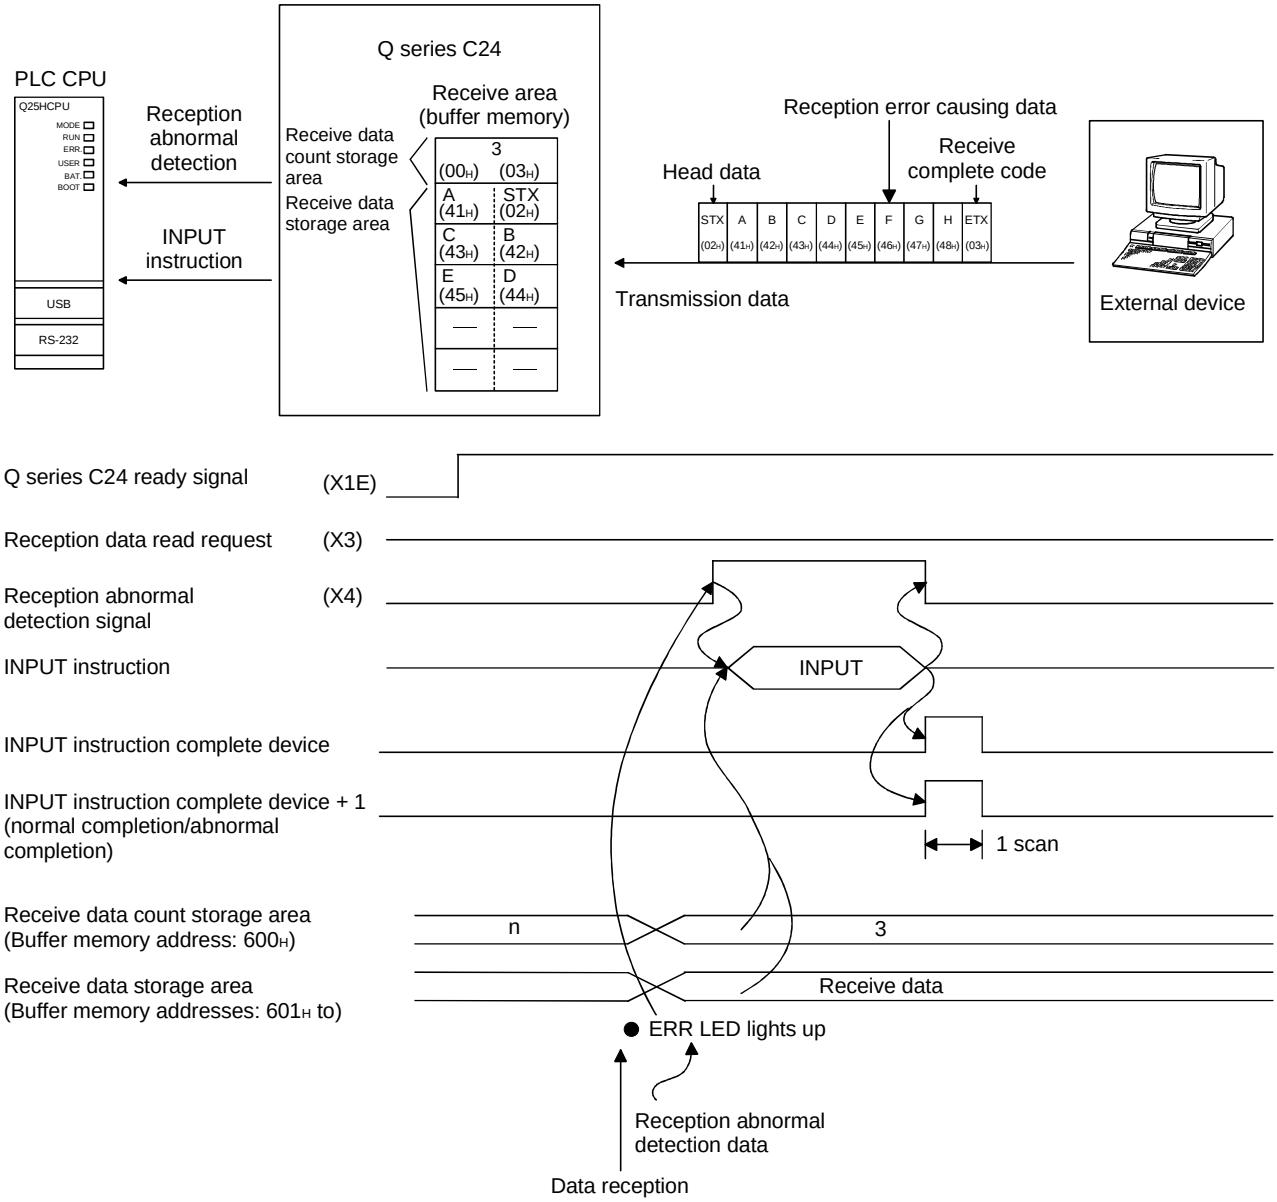
(2) Confirmation using the module and QSCU

1) Confirmation using the display LED
   When the Q series C24 detects an error, including a transmission error, the ERR LED lights up. (See Chapter 10.)
2) Confirmation using QSCU
   - The monitor function is used to check for errors. (See Sections 8.6.3 and 8.6.5.)
   - The ERR LED is turned off with the ERR LED OFF function. (See Section 8.6.10.)
3) Confirming the error code
   Use one of the following to confirm the error code.
   - QSCU monitor function (See Section 8.6.5.)
   - GX Developer buffer memory monitor function (monitors addresses 258H/268H)

(3) Receive data when a reception error occurs

(a) Storing receive data
The receive data for which an error was detected is discarded and only the normally received data is stored in the Q series C24.
Thus, there may be missing data among the data that has been read to the PLC CPU when a reception error occurs.

(b) Reading receive data
When receive data is read to the PLC CPU by turning the reception abnormal detection signal (X4/XB) ON, the data that was normally received prior to the error detection is read. Read and discard receive data as needed.



* When the data from "G" to in the reception message shown in the figure above is received normally, the data is stored in the Q series C24 OS area.
The receive data stored in the OS area will be read to the PLC CPU in the succeeding read operation.

6.1.6 Received data count and receive complete code settings

The following default values have been set for the received data count and receive complete code that are used for data reception with the non procedure protocol.
If it is necessary to change the following default settings, change the settings on the QSCU "Non procedure system setting" screen according to the specifications of the external device (see Sections 8.4.5 and 8.4.7).

Setting data	Default value	Allowable range	Buffer memory address where the setting value is stored	Remarks
Received data count	511 (1FF$_H$)	Less than the size of the receive data storage area	A4$_H$/144$_H$	Unit is in accordance with the word/byte units designation
Receive complete code	0D0A$_H$ (CR, LF)	0000$_H$ to 00FF$_H$	A5$_H$/145$_H$	When any code is set
		FFFF$_H$		When there is no receive complete code

REMARK

Other than through the setting using QSCU or the T0 instruction at the startup of the Q series C24, the received data count and receive complete code setting values can be changed even after data communication has started if the timing is as shown in the chart below.
The following describes the procedure for changing setting values for data reception via the non procedure protocol after the start of data communication, and for the resumption of data reception processing. Specifically, the module restrictions are explained, along with the timing and procedure for changing the setting values.

(1) Data receiving method

Reception using a dedicated instruction (INPUT) or an interrupt program (*1) cannot be performed. (Transmission using a dedicated instruction (OUTPUT) can be performed.) Data must be received using the FROM instruction in the main program.
The following describes the I/O signals. (A program example is shown on the following page.)

*1 For details on the data reception using interrupt programs, see the User's Manual (Application).

	I/O signal		Signal name	Device that turns ON/OFF		Timing
	CH1 side	CH2 side		CPU	Q series C24	
Reception	X3	XA	Reception data read request		○		X4	XB	Reception abnormal detection		○	
	Y1	Y8	Reception data read completion	○		

POINT

When the reception abnormal detection signal (X4/XB) turns ON, read the error code from the buffer memory below, and then check the type of error and take corrective action based on the information found in Chapter 10.

- Data reception result storage area (addresses 258/268$_H$)

(2) Setting values that can be changed

Of the initial settings from QSCU stored in the buffer memory, only the following setting values can be changed after data communication has started.

- Received data count (buffer memory addresses: A4H, 144H)
- Receive complete code (buffer memory addresses: A5H, 145H)

(3) Timing and procedure for changing the setting values

1) Timing of change

To change the receive complete code and received data count after data communication has started, change the setting when the status of the I/O signals relating to the reading of receive data is as follows.

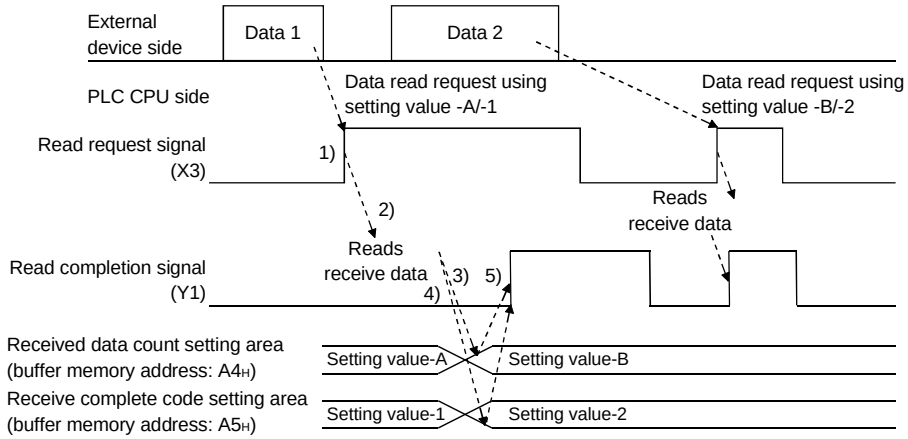
- Reception data read request signal (X3, XA) or reception abnormal detection signal (X4, XB): ON
- Reception data read completion signal (X1, Y8): OFF

2) Change procedure

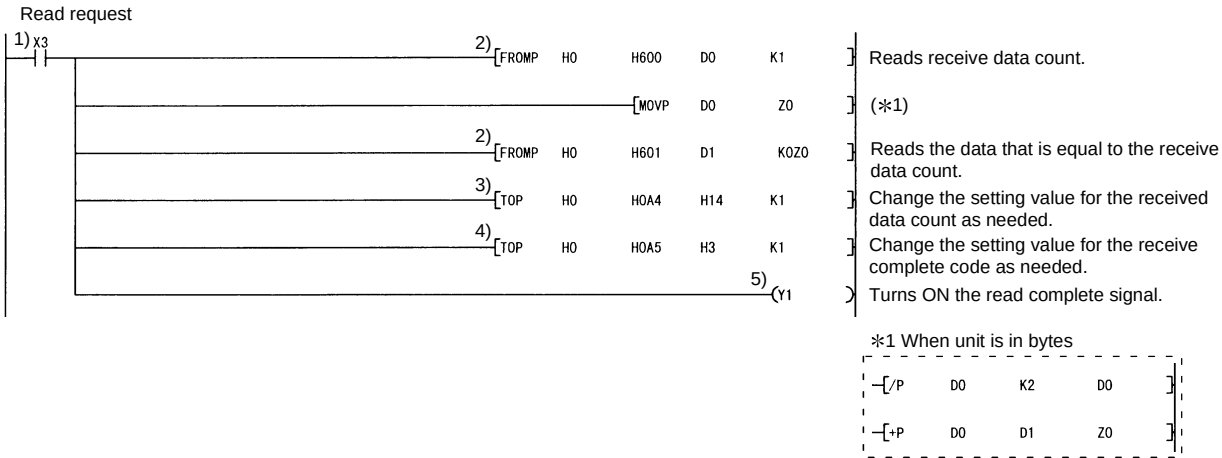
When data reception from an external device causes the reception data read request signal/reception abnormal detection signal to turn ON, turn ON the reception data read completion signal after performing the following.

- Read the receive data.
- Change the setting values for the receive complete code and the received data count.

(Example) When reading data received in the CH1 side interface



(Program example: I/O signals for the Q series C24 are from X/Y00 to X/Y1F)

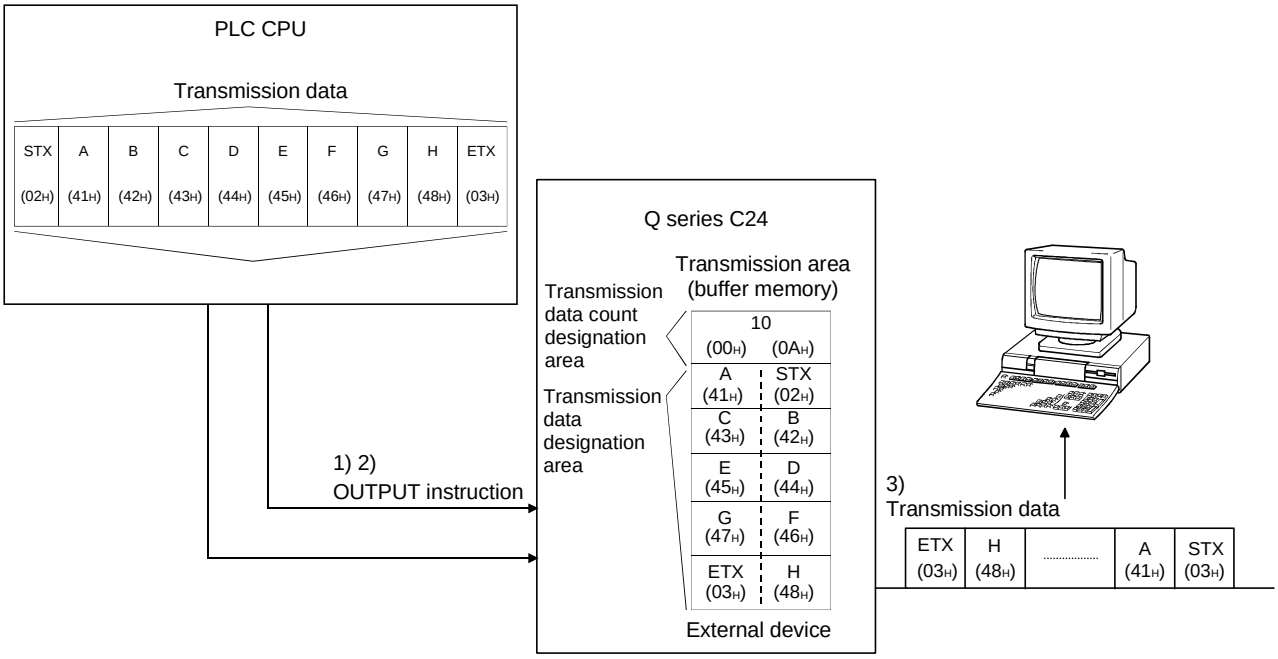


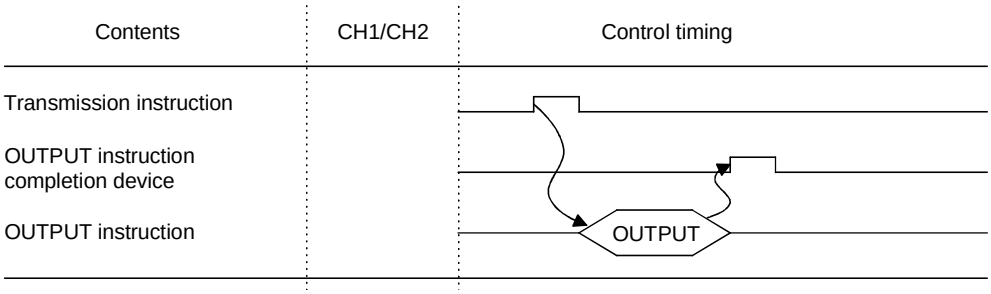
6.2 Sending Data to the External Device

This section explains data transmission from the PLC CPU to the external device.

6.2.1 Transmission methods

The following shows how to send data in any format using the non procedure protocol.





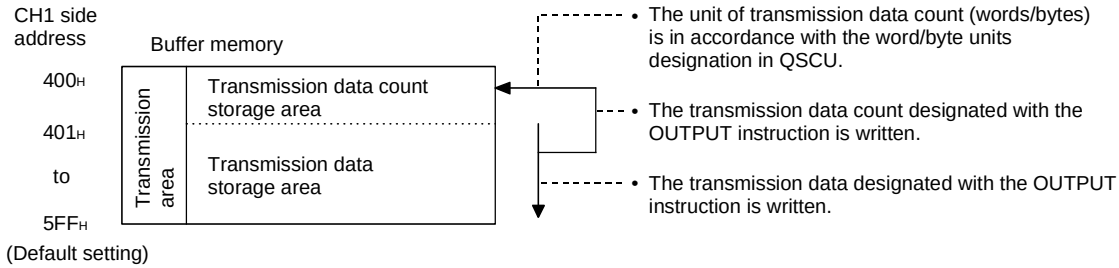
1) Transmission data is stored in the device designated with the OUTPUT instruction.
2) Control data is stored in the device designated with the OUTPUT instruction.
3) When the OUTPUT instruction is executed, the Q series C24 sends the amount of data designated by the transmission data count from the transmission data area to the external device in ascending order of the transmission data area addresses.

6.2.2 Arrangement and contents of the transmission area and the transmission data

This section explains the arrangement and contents of the transmission area and the transmission data for performing data transmission using the non procedure protocol.

(1) Transmission area

The transmission area is a memory area for storing the data and the data count that are transmitted from the PLC CPU to the external device via the Q series C24. By default, the transmission area is assigned to addresses 400H to 5FFH (CH1 side) and 800H to 9FFH (CH2 side).



POINT

(1) The position and size of the transmission area in the buffer memory can be changed with QSCU in accordance with the specifications of the external device and the received data length. (See Sections 8.4.5 and 8.4.7.)

(a) When changing the position and size of the transmission area in the buffer memory with QSCU, specify as follows:

1) Transmission buffer memory head address designation
Designate the starting address for the area to be used as the transmission area in the user definable area of the buffer memory.
2) Transmission buffer memory length designation
Designate by addresses the length of the area to be used as the transmission area in the user definable area of the buffer memory.

(b) If the following functions are also used when the position and size of the transmission area in the buffer memory are changed, make sure that the addresses of the transmission area do not overlap with those for the buffer memory that stores the transmission and receive data to be used by these functions.

1) MC protocol buffer memory read/write function
2) MC protocol on-demand function
3) Non procedure protocol transmission/receive function
4) Bidirectional protocol transmission/receive function

(2) Set the size of data per data transmission from the PLC CPU to the external device so that it is smaller than the size of the transmission data's designated area in the buffer memory.

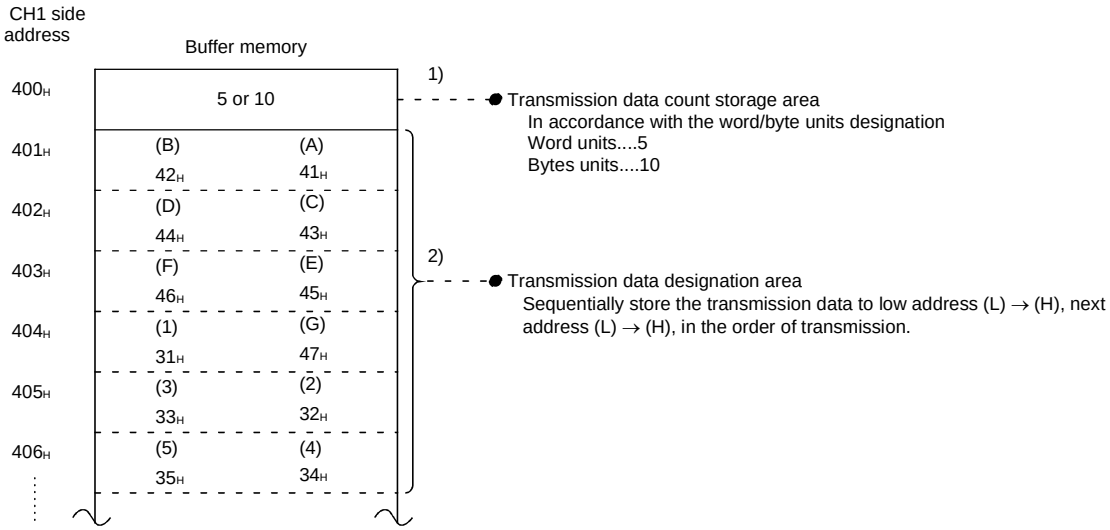
(Transmission data designation area) ≧ (Size of arbitrary data portion to be sent from the PLC CPU)

To transmit data whose size is larger than the transmission data designation area, increase the transmission area, or divide the transmission data before sending.

(2) Transmission data arrangement

The following example shows an arrangement of the transmission data to be sent to the external device when storing it in the transmission area.

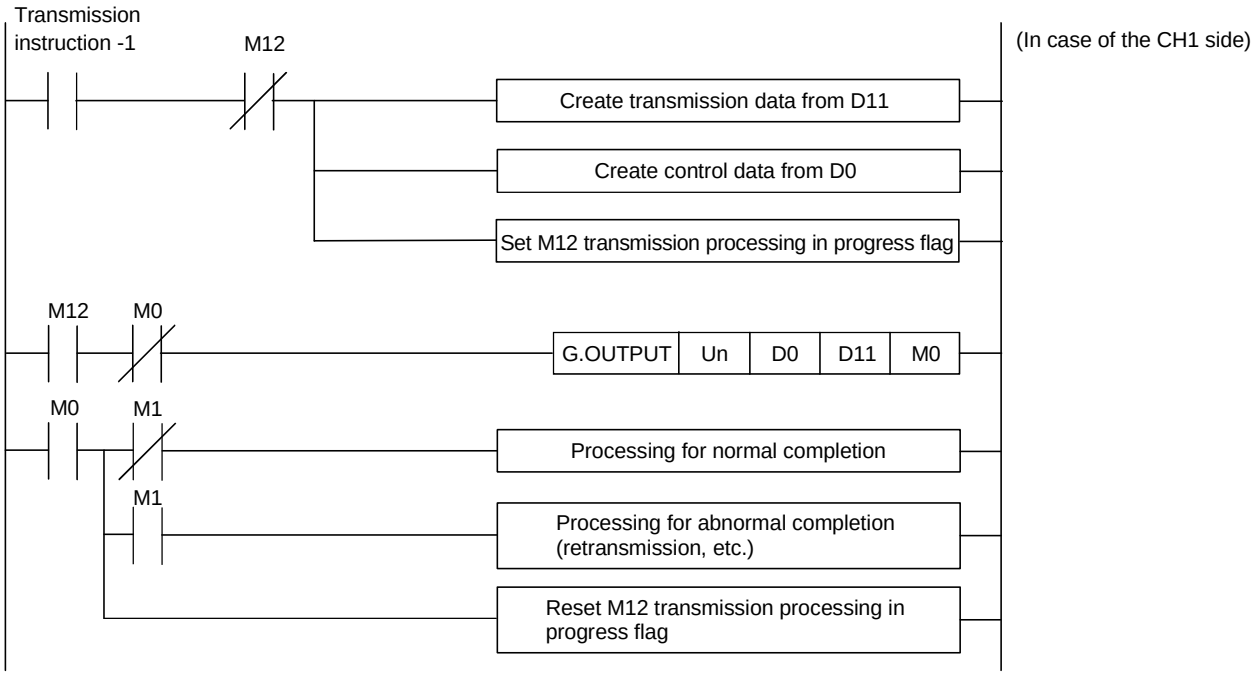
(Example) When transmitting "ABCDEFG123" (The transmit area is the default value.)

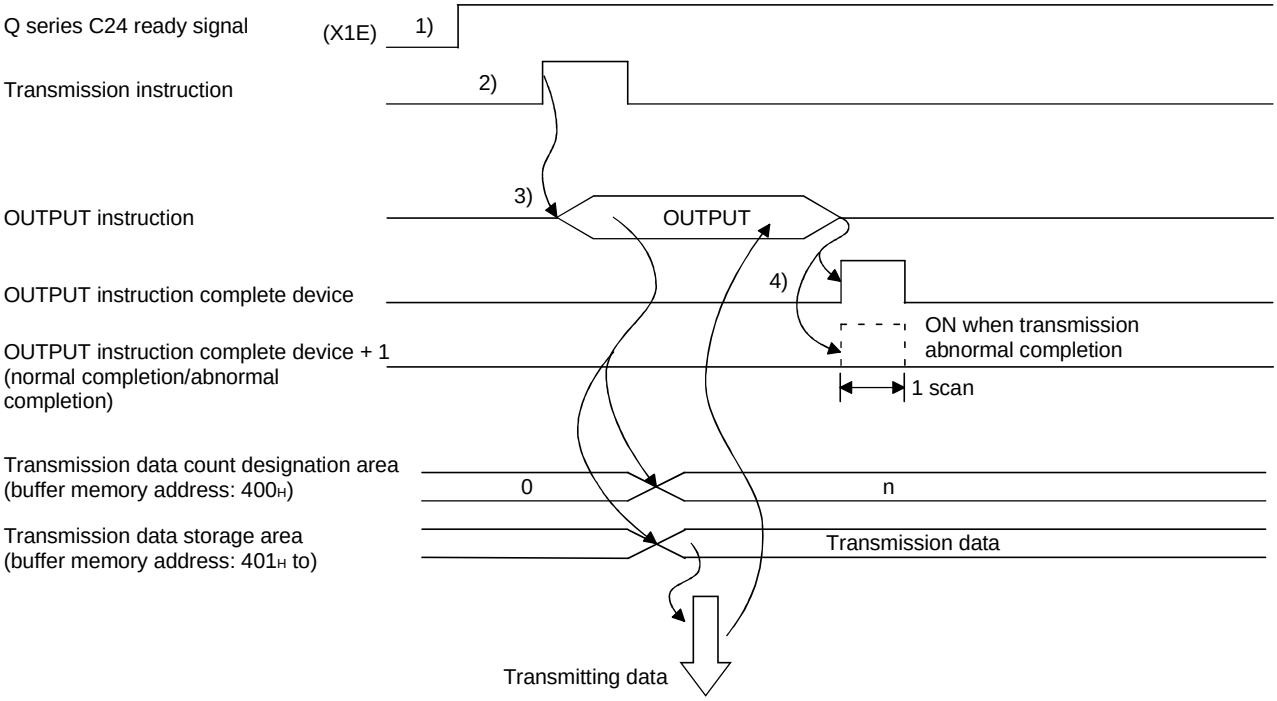


6.2.3 Sequence program for transmission data

A sequence program for transmission data is explained below.

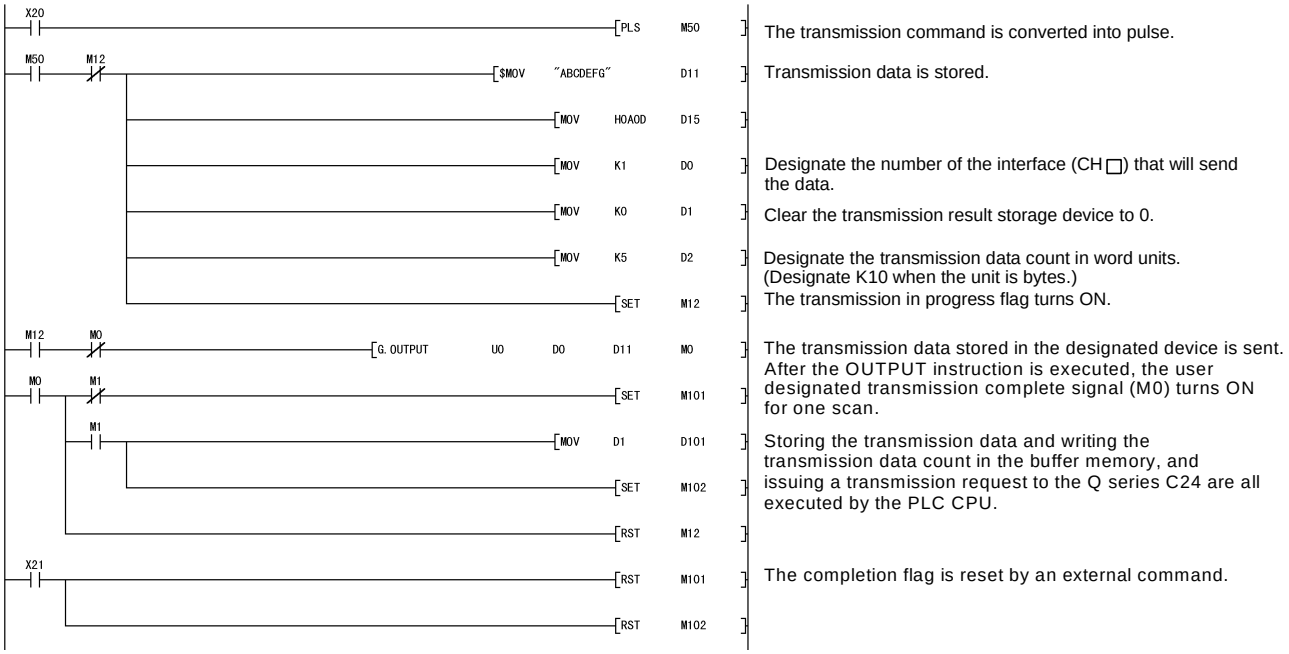
For details on the OUTPUT instruction used for data transmission, see Chapter 9.

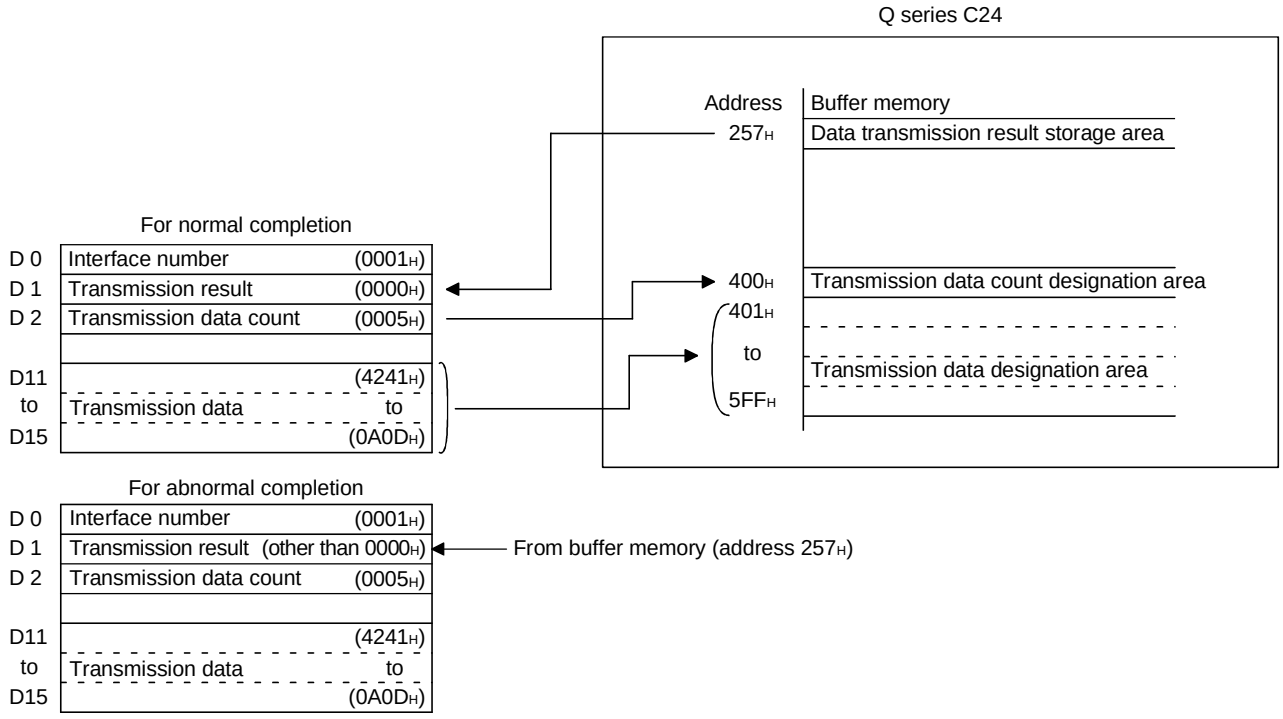




1) Starts the local station PLC.
   The setting values for GX Developer are stored in the Q series C24.
2) Inputs the user data transmission command signal.
3) Executes the OUTPUT instruction after storing the transmission data and the control data for the OUTPUT instruction in the device.
   Data is sent when the OUTPUT instruction is executed.
4) When the Q series C24 transmission processing completes, the completion device for the OUTPUT instruction turns ON.
   When the completion device + 1 (abnormal completion signal) turns ON, the error code is stored in the control data completion status (S1+1).

(Program example)
When Q series C24 I/O signals are from X/Y00 to X/Y1F:





POINT

(1) The SPBUSY instruction is used to read the execution status when using a dedicated instruction. (See Chapter 9.)

(2) More than one OUTPUT instruction cannot be executed simultaneously. Execute the next OUTPUT instruction only after the execution of the first OUTPUT instruction is completed.

6.2.4 How to detect transmission errors

This section explains how to detect errors that may occur when sending data to the external device.

The following items are considered as the primary causes of errors that may occur during data transmission.

Cause of reception error	Reference section	
A timeout occurred for the transmission monitoring time (timer 2)	User's Manual (Application)	Section 6.3
Designated number of transmission data was larger than the size that could be stored in the transmission area	Section 6.2.2	

(1) Confirmation using the sequence program

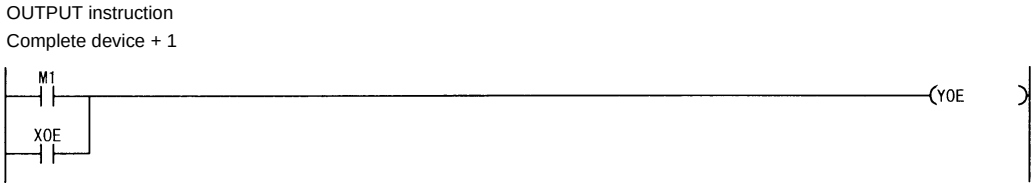
(a) Detecting a transmission error

1) The following device and input signal turn ON.
   - OUTPUT instruction complete device + 1
   - ERR LED ON signal (XE/XF)
2) The transmission error code can be checked using the OUTPUT instruction control data ((S1) + 1).
   Or, it can be checked by reading the data transmission result storage area in the buffer memory (addresses 257H/267H).
   For details on how to check the error code contents and corrective actions, see Chapter 10.

(b) How to turn off the ERR LED and clear the error code (see Section 10.1.2)

1) To turn off only the ERR LED, write a "1" to the LED OFF request area (addresses 0H/1H) in the buffer memory.
2) To turn off the ERR LED and clear the error code, turn ON the ERR LED OFF request output signal (YE/YF).

(Example) To perform the ERR LED OFF and the error code clear on the CH1 side



(2) Confirmation using the module and QSCU

1) Confirmation using the display LED
   When the Q series C24 detects an error, including a transmission error, the ERR LED lights up. (See Chapter 10.)
2) Confirmation using the QSCU
   - The monitor function is used to check for errors. (See Sections 8.6.3 and 8.6.5.)
   - The ERR LED is turned off with the ERR LED OFF function. (See Section 8.6.10.)
3) Confirming the error code
   Use one of the following to confirm the error code.
   - QSCU monitor function (See Section 8.6.5.)
   - GX Developer buffer memory monitor function (monitors addresses 257H/267H)

POINT
When a transmission error occurs, the PLC CPU may not transmit all the designated data. It is recommended that data communications be performed by establishing a user arbitrary communication procedure that can check normal transmission by reception of a response to data transmission.

6.3 Data Communications Precautions

The following describes the precautions to be taken during non procedure protocol data communications.

(1) The Q series C24 transmission sequence initialization conditions

The initial status indicates the status where transmission has stopped and reception data has been discarded.
The Q series C24 transmission sequence initialization conditions are as follows.

1) When the power is turned on, the Reset switch on the CPU panel is operated, or the Q series C24 mode is switched
2) When the receive data was cleared.
3) When the CD signal was turned off when data communications were performed by setting CD terminal check enable during full-duplex communications through the RS-232 interface.

(2) Generation of framing error in external device

When nothing is transmitted from the Q series C24 to the external device through the RS-422 or RS-422/485 interface, a framing error may be generated by the noise etc, in the external device.
Send an arbitrary code to identify the head of the send data from the Q series C24 to the external device.
Before data communication check the Q series C24 interface specifications.

(3) Data communications with external device (computer, etc.) over a multidrop link

When the external device PLC CPU are connected by a 1:n multidrop link, each the Q series C24 receives the data transmitted by the external device.
With a multidrop link, receive data by user frame (*1).
If data is not received by user frame, a sequence program that ignores the receive data other than the receive data addressed to the local station by sequence program, including the data indicating the objective PLC CPU in the message, must be written.
(Sample message)

(Example)

STX	Space	Station No. 0	Station No. 2	Data length (BIN data)	Data	CR	LF
(02_H)	(20_H)	(32_H)	(32_H)			($0D_H$)	($0A_H$)

*1 See chapter 11 of User's Manual (Application)

(4) Retry processing for data reception errors

The data when reception error occurred is discarded and only the data for the normal reception is taken into the Q series C24. For this reason, the reception message may be missing data when an error occurs. To assure the correct transmission and reception of data it is recommended that a normal/error response message is received and a response message reception timeout check is conducted for data transmitted between the PLC CPU and the external equipment and that measures be taken when an error message is received or when an error timeout occurs, such as retransmitting the data (transmission retry).

7 DATA COMMUNICATION USING THE BIDIRECTIONAL PROTOCOL

Data communication using the bidirectional protocol is a function for sending/receiving any data using the message format and transmission control procedure for the Q series C24 bidirectional protocol between external devices and PLC CPUs.
Any external devices that can install application programs and transmit and receive data in accordance with the MELSEC PLC protocol can communicate with the PLC CPUs using the bidirectional protocol.

This chapter explains the basic transmission and reception methods when performing data communication using the bidirectional protocol.
Follow the procedure described in this chapter to create sequence programs for sending and receiving data for the PLC CPU.
Regarding the additional functions listed below for data communication using the bidirectional protocol, see the separate User's Manuals (Application)

- Reading receive data using interrupt programs
  (See Chapter 4 of Application)
- Sending/receiving data using ASCII data (ASCII-BIN conversion)
  (See Chapter 13 of Application)
- Sending/receiving data using transparent code designation
  (See Chapter 12 of Application)

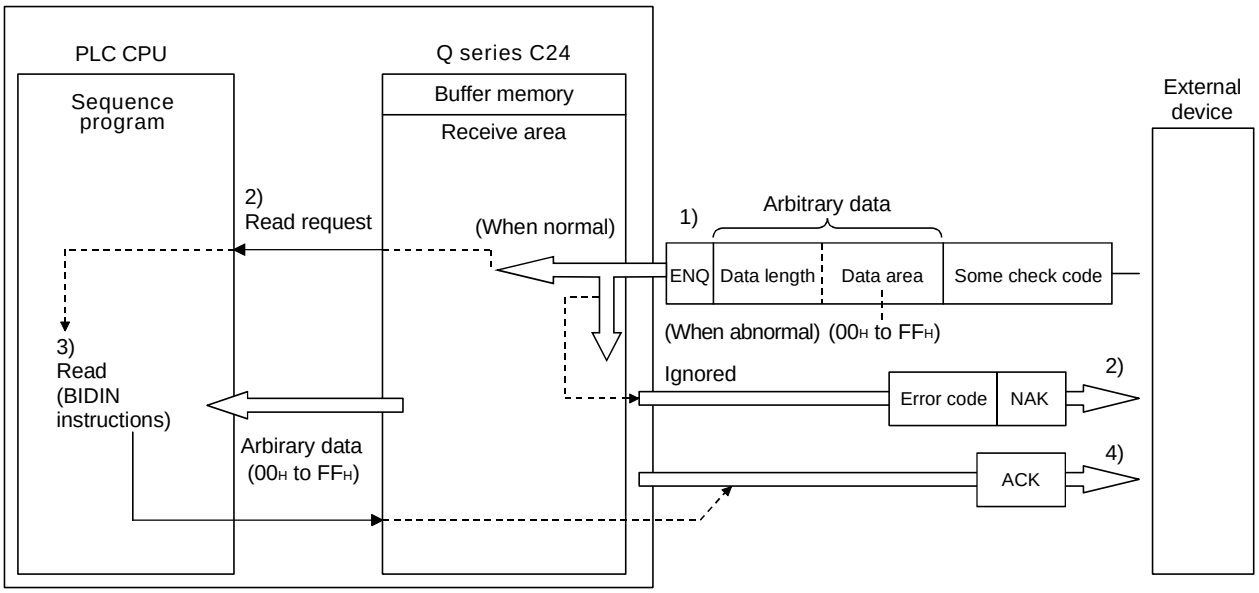
7 - 1

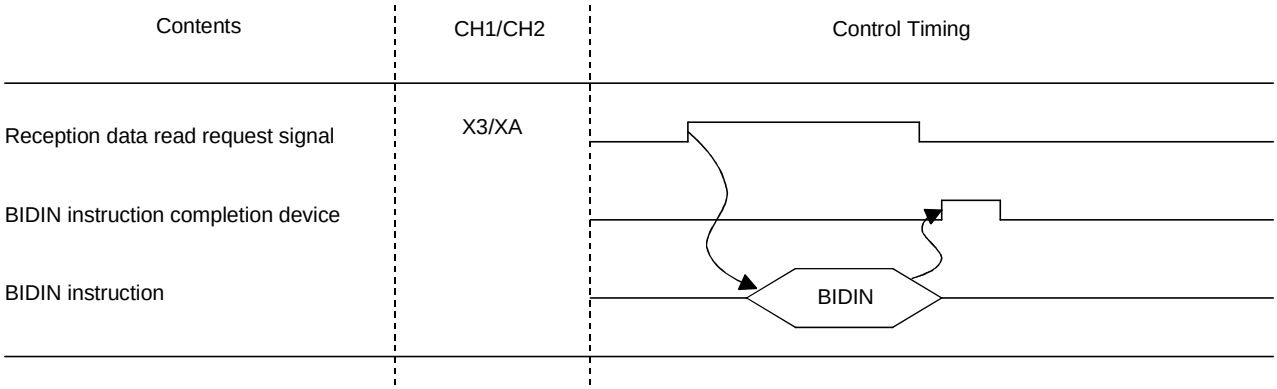
7.1 Data Reception from the External Device

This section explains the data reception from the external device.

7.1.1 Receiving methods

The following shows how to receive data sent from the external device using the bidirectional protocol. Since the size of each message received is recognized using the "data length" information contained in the message, messages of any size can be sent from the external device.





7 - 2

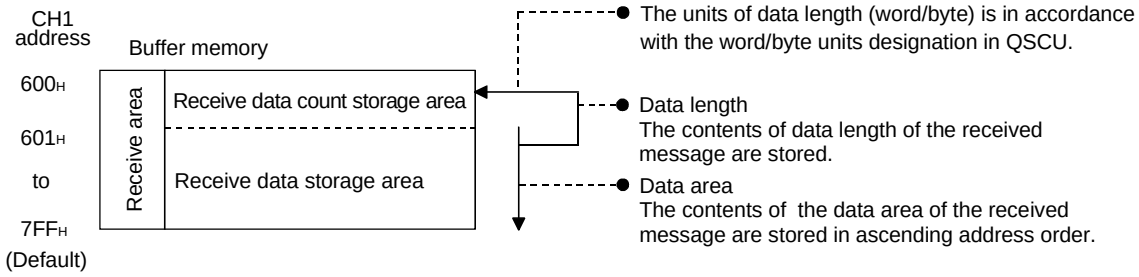
1) When the control code ENQ is received, the Q series C24 starts data reception processing.
   When the data specified by the data length is received, the Q series C24 ends the reception processing of that data.
   If "Sum check" is set with GX Developer, the Q series C24 checks whether the message is normal or abnormal using the sum check code received immediately after the message and the sum check code calculated by internal processing.
   ✻ If "No sum check" is set with GX Developer, messages are not checked using the sum check codes.
2) If the message has normally been received, the reception data read request signal turns ON.
   ✻ If an error has been detected when receiving the message, the Q series C24 sends an abnormal end response (NAK message) to the external device.
   The reception data read request will not be sent to the PLC CPU.
3) Control data is stored in the device designated with the BIDIN instruction and then the BIDIN instruction is executed.
   Receive data is read from the receive area of the buffer memory.
4) When the BIDIN instruction has been executed, the Q series C24 sends a normal end response (ACK message) to the external device.

7.1.2 Arrangement and contents of the receive area and the receive data

This section shows the arrangement and contents of the receive area and the receive data for performing data reception using the bidirectional protocol.

(1) Receive area

The receive area is a memory that stores the received data length (receive data count) and data area received from an external device.
The receive area is allocated to addresses 600H to 7FFH (CH1 side) and A00H to BFFH (CH2 side) at initial setting.



POINT

(1) The position and size of the receive area in the buffer memory can be changed with QSCU in accordance with the specifications of the external device and the received data length. (See Sections 8.4.5 and 8.4.7.)

(a) When changing the position and size of the receive area in the buffer memory with QSCU, specify as follows:

1) Receive buffer memory head address designation
Designate the starting address for the area to be used as the receive area in the user definable area of the buffer memory.
2) Receive buffer memory length designation
Designate by addresses the length of the area to be used as the receive area in the user definable area of the buffer memory.

(b) If the following functions are also used when the position and size of the receive area in the buffer memory are changed, make sure that the addresses of the receive area do not overlap with those for the buffer memory that stores the transmission and reception data to be used by these functions.

1) MC protocol buffer memory read/write function
2) MC protocol on-demand function
3) Non procedure protocol transmission/receive function
4) Bidirectional protocol transmission/receive function

(2) When sending data to the Q series C24 from the external device, one of the following two adjustments should be made so that the relationship shown below is maintained.

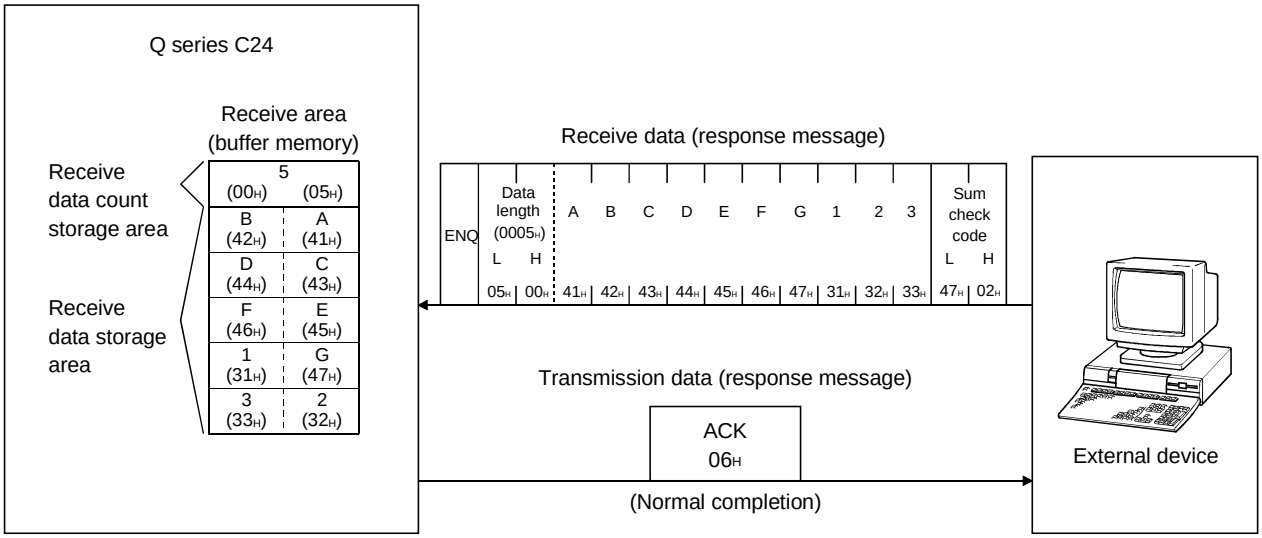
1) Reduce the send data size.
2) Increase the receive area.

(Receive data storage area) ≧ (Size of data portion sent from the external device)

(2) Arrangement of receive data

The following example illustrates the arrangement of data received from the external device when it is stored in the receive area.

1) The receive message is stored to the Q series C24 buffer memory (receive data storage area).
2) The data is stored to the receive data storage area in low address (L) → (H), next address (L) → (H) order.
   If the received data is "ABCDEFG123", it will be stored as shown below (for the CH1 side):



∗ When the data length unit is in bytes, 00H is stored in the higher byte of the last data storage position in the receive area when the data length of the message is an even byte.

(3) Contents of receive data

∗ The contents of receive data, including the receive data as indicated in Section 7.2.2, are explained below.

(a) Control codes

The types of control codes are shown in the table below.

Signal name	Code (hexadecimal)	Contents	Application
ENQ	05H	Enquiry	Code for starting data transmission.
ACK	06H	Acknowledge	Response code to the opposite side when data was received normally.
NAK	15H	Negative Acknowledge	Response code to the opposite side when data could not be received normally. (Error code is sent immediately after the response code.)

1) For data communication from the external device to the Q series C24 the Q series C24 checks and processes the control code received. It cannot be read from the sequence program.
2) For data communication from the Q series C24 to the external device The control code to be transmitted is added by the Q series C24.

(b) Data length

This indicates the number of bytes or words for the data portion of the message.

The unit of data length (words/bytes) is in accordance with the word/byte units designation in QSCU.

1) For data communication from the external device to the Q series C24
The Q series C24 checks the length of the data received.
When the reception is normal, the Q series C24 stores the receive data in the receive data storage area of the Q series C24 buffer memory, assigning the first byte as the lower byte (L).
2) For data communication from the Q series C24 to the external device
The length of the transmission data is the number of the transmission data designated by the sequence program using the BIDOUT instruction.
The Q series C24 sends this value as is from the lower byte (L).

(c) Data portion

This consists of an array of original one-byte data to be transmitted to the external device side, which can handle 00_H to FF_H code data.

1) For data communication from the external device to the Q series C24
If the receive data portion is normal, the Q series C24 takes the codes as is and stores them in the receive data storage area in sequence, beginning with the youngest address.
The storage size is in accordance with the data length in the message (See item (b) above) and the word/byte units designation in QSCU.
2) For data communication from the Q series C24 to the external device
The transmission data portion is the number of the transmission data designated by the sequence program using the BIDOUT instruction.
The Q series C24 sends the transmission data using the existing codes until the transmission data count is reached in accordance with the word/byte units designation in QSCU to the transmission data designation area.

(d) Sum check code

The sum check code expresses the numeric value for the lower two bytes (16 bits) of the results (sum) from the addition of the data length and the data portion in the message as binary code data.

When "Sum check" is specified with the transmission setting in GX Developer, it is necessary to add a sum check code at the end of the message.

1) For data communication from the external device to the Q series C24

The Q series C24 checks and processes the sum check code received. It cannot be read from the sequence program.

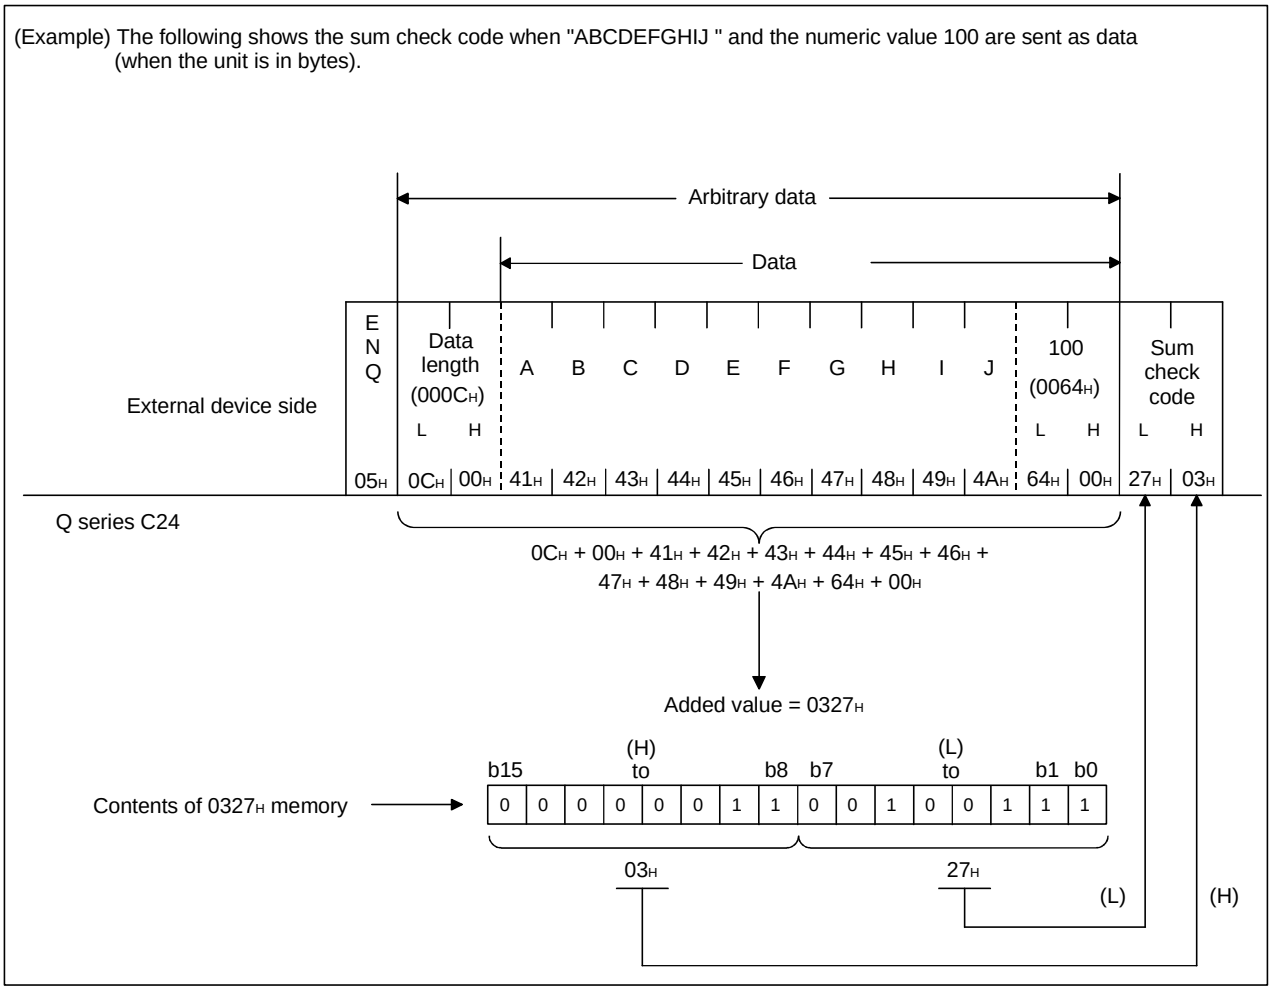
When "No sum check" is specified, once a data portion of message corresponding to the data length is received, the succeeding data received will be ignored up to the control code that follows (See (a)).

The following example shows the contents of a sum check code in the message.

2) For data communication from the Q series C24 to the external device

The sum check code to be transmitted is calculated and added by the Q series C24. When "No sum check" is specified, no sum check code is transmitted.

(Example) The following shows the sum check code when "ABCDEFGHIJ " and the numeric value 100 are sent as data (when the unit is in bytes).



(e) Error code

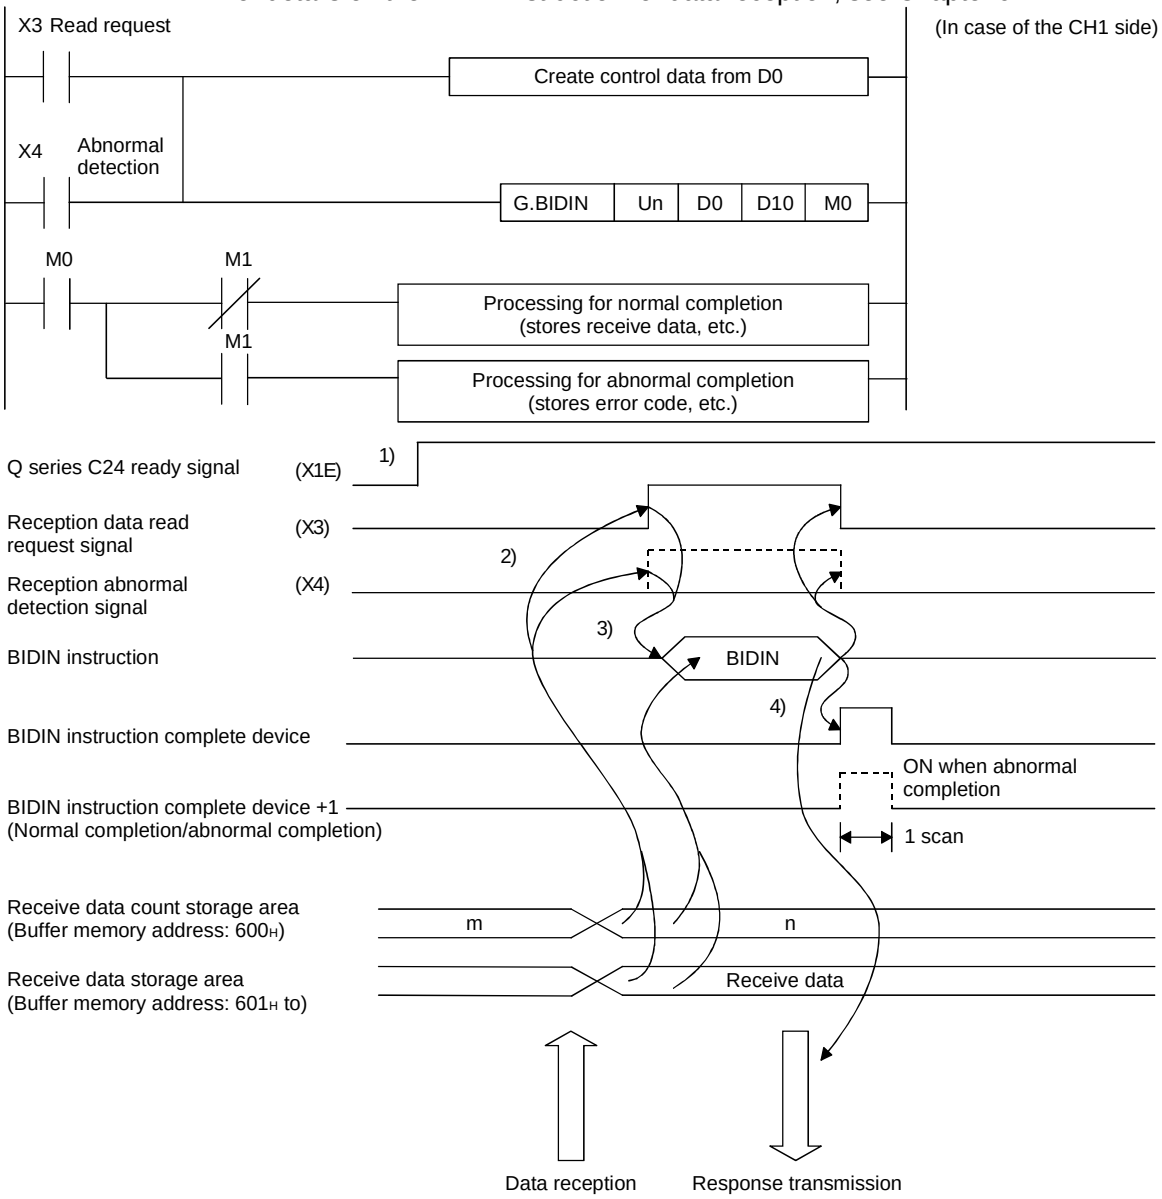
The error code indicates the definition of the error during NAK response. (For more details on the error codes, see Chapter 10.)

1) For data communication from the external device to the Q series C24
Transmit 0022_H to $005F_H$ as error codes.
The Q series C24 stores the received error codes as a completion status in the control code for the BIDOUT instruction.
They are also stored in the data transmission result storage area in the buffer memory (address: 257_H).

2) For data communication from the Q series C24 to the external device
The error codes are added by the Q series C24.
When an error code is transmitted, the Q series C24 writes the same error code in the data reception result storage area of the buffer memory (address: 258_H).
Since the error codes are defined by the user, corrective actions should be taken based on the definition of the error for which the corresponding error code has been assigned.

7.1.3 Sequence program for data reception

This section explains the sequence program for data reception.
For details on the BIDIN instruction for data reception, see Chapter 9.

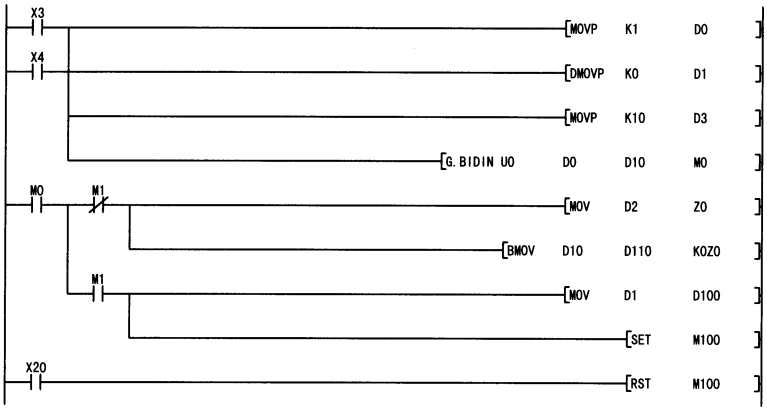


1) Start the local station PLC.
   The values specified with GX Developer are stored in the Q series C24.
2) When data is received from the external device, the reception data read request signal turns ON.
3) After the control data for the BIDIN instruction is stored in the device, the sequence program executes the BIDIN instruction and reads the receive data.
4) When the reading of receive data is completed, a response message (ACK message when the operation was completed normally) is sent and the device that has completed the BIDIN instruction turns ON. When the complete device + 1 (abnormal completion signal) turns ON, the error code is stored in the control data completion status (S1+1).

(Program example)

When Q series C24 I/O signals are from X/Y00 to X/Y1F:

Read request



Designate the interface number (CH☐) that reads the receive data.

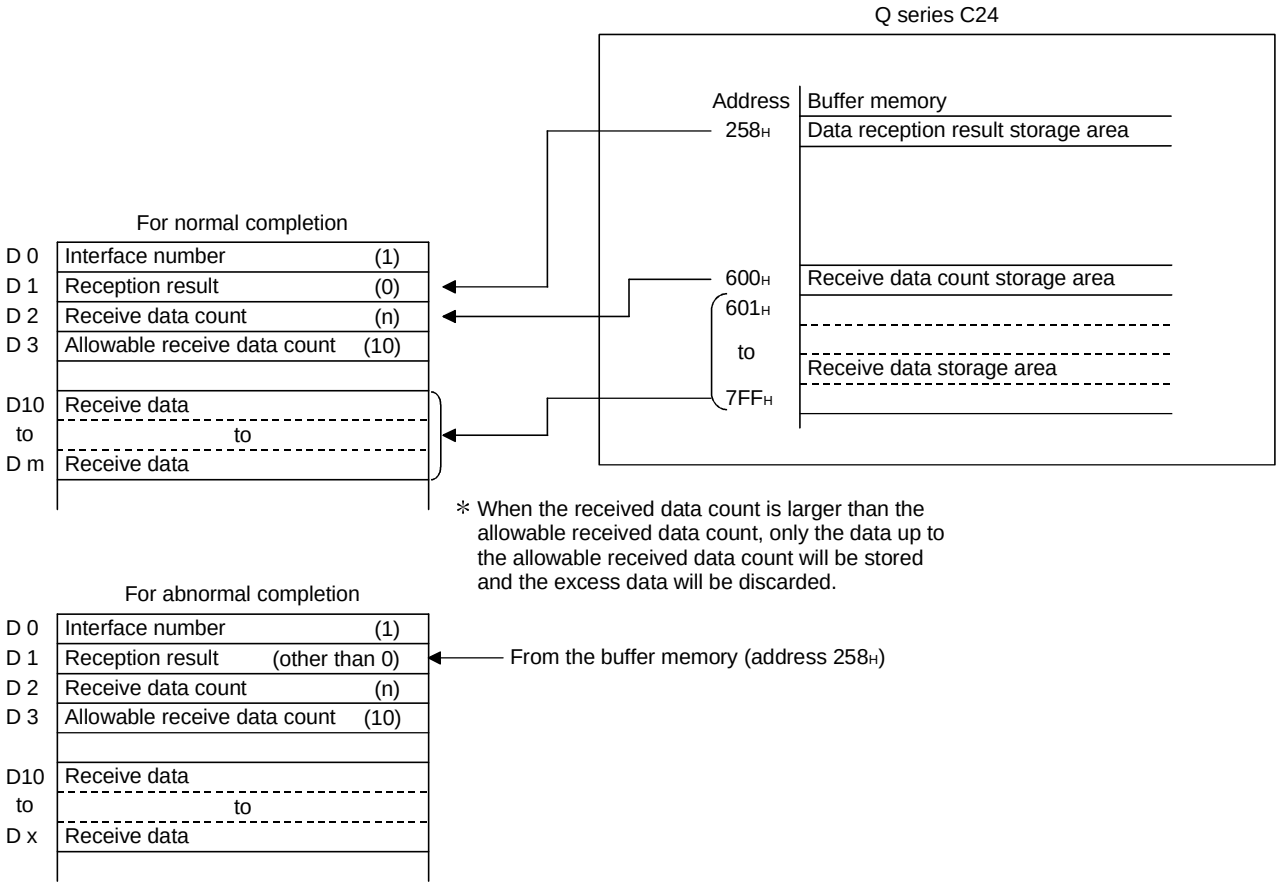
Clear the reception result and receive data count storage device to 0.

Designate the allowable receive data count.

With normal completion, the receive data within the allowable receive data count (user designated) is read from the receive data storage area in the buffer memory.

- After the BIDIN instruction is executed, the user designated read completion signal (M0) turns ON for 1 scan.
- The reading of receive data and switching of the ON/OFF status of a read completion signal are performed by the PLC CPU.

The abnormal completion flag is reset by the external instruction.



* When the received data count is larger than the allowable received data count, only the data up to the allowable received data count will be stored and the excess data will be discarded.

POINT

(1) Receive data can also be read using interrupt programs.
For more details on reading receive data with interrupt programs, see Chapter 4 of the User's Manual (Application).
Note that if the reading of data received from the same interface is to be performed, it is not possible to combine the reading of data received by the main program and reading of data received by the interrupt program.
Accordingly, use one or the other of the above programs to read the data received.

(2) The SPBUSY instruction is used to read the execution status when using a dedicated instruction. (See Chapter 9.)

(3) More than one BIDIN instruction cannot be executed simultaneously.
Execute the next BIDIN instruction only after the execution of the first BIDIN instruction is completed.

(4) If the communication data count is set in byte units and the receive data count is an odd byte when requesting the reading of receive data to the PLC CPU, 00H is stored in the higher byte of the final data storage position in the receive data storage area.

7.1.4 How to detect reception errors

This section explains how to detect errors that may occur when receiving data from the external device.

The following items are considered as the primary causes of errors that may occur during data reception.

Cause of reception error	Reference section	
A transmission error occurred because of noise.	—	
A timeout occurred for the no-reception monitoring time (timer 0).	User's Manual (Application)	Section 6.1
A timeout occurred for the transmission monitoring time (timer 2)		Section 6.2
Data that could not be converted with the ASCII-BIN conversion was detected.		Chapter 13
Received the data length that was too long to store in the receiving area.	Section 7.1.2	
Simultaneous transmissions occurred.	Section 7.3	

(1) Confirmation using the sequence program

(a) Detecting the occurrence of a reception error

1) The following device and input signal turn ON.
   - BIDIN instruction complete device + 1
   - ERR LED ON signal (XE/XF)
2) The reception error code can be checked using the BIDIN instruction control data ((S1) + 1).
   Or, it can be checked by reading the data reception result storage area in the buffer memory (addresses 258H/268H).
   For details on how to check the error code contents and corrective actions, see Chapter 10.

(b) How to turn off the ERR LED and clear the error code (see Section 10.1.2)

1) To turn off only the ERR LED, write a "1" to the LED OFF request area (addresses 0H/1H) in the buffer memory.
2) To turn off the ERR LED and clear the error code, turn ON the ERR LED OFF request output signal (YE/YF).
   (Example) To perform the ERR LED OFF and the error code clear on the CH1 side

(2) Confirmation using the module and QSCU

1) Confirmation using the display LED
   When the Q series C24 detects an error, including a transmission error, the ERR LED lights up. (See Chapter 10.)
2) Confirmation using QSCU
   - The monitor function is used to check for errors. (See Sections 8.6.3 and 8.6.6.)
   - The ERR LED is turned off with the ERR LED OFF function. (See Section 8.6.10.)
3) Confirming the error code
   Use one of the following to confirm the error code.
   - QSCU monitor function (See Section 8.6.6.)
   - GX Developer buffer memory monitor function (monitors addresses 258H/268H)

(3) Handling of receive data when a reception error occurs

1) All of the receive data for which an error was detected is ignored and an response message indicating an abnormal completion (NAK message) is sent to the external device.
   ✻ When an error is detected during message reception, the Q series C24 does not issue a reception data read request to the PLC CPU.
2) The receive area in the buffer memory will contain the data received normally just prior to the error occurrence. (Data will not be rewritten.)

7.1.5 Receive data clear

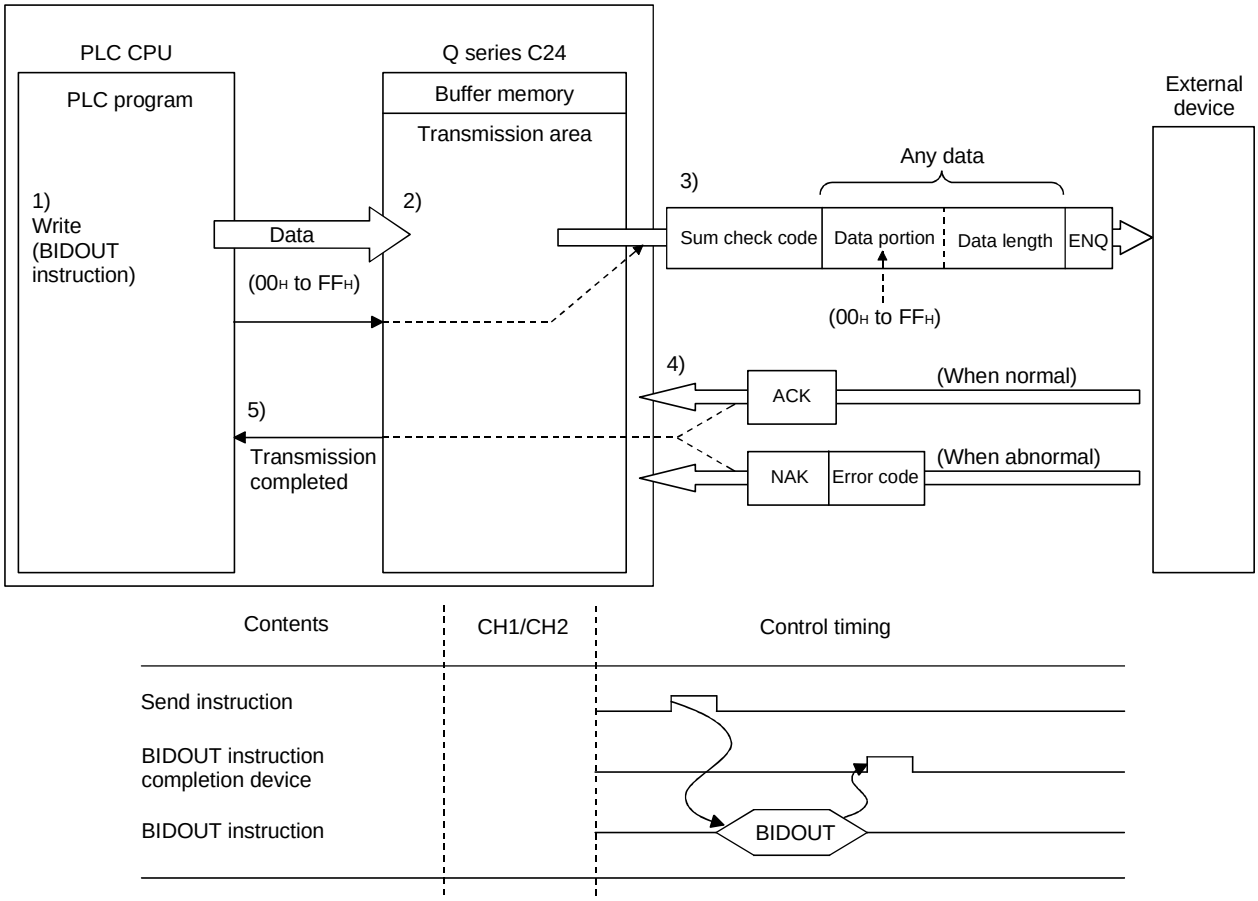
Data communications using the bidirectional protocol must be performed after a response message is received in reply to the preceding data transmission.
If the Q series C24 detects an error while receiving data, it sends an NAK message (response message) to the external device after the data reception completion and ignores the data being received when the error was detected.
Therefore, the receive data does not have to be cleared.

7.2 Sending Data to the External Device

This section explains data transmission from the PLC CPU to the external device.

7.2.1 Transmission methods

The following shows the method of sending data to the external device through data communication using the bidirectional protocol.



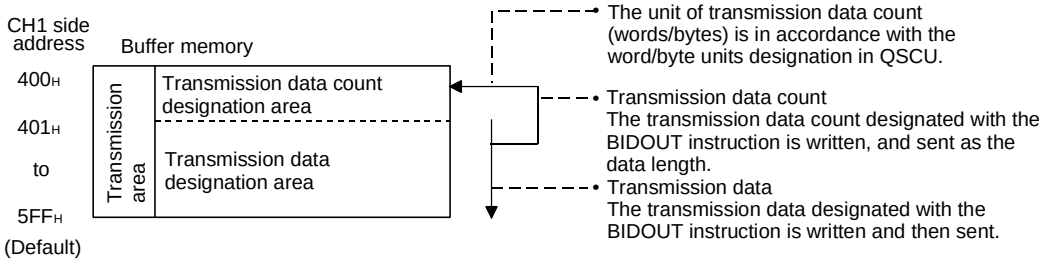
1) Data such as control data and transmission data are stored in the device designated with the BIDOUT instruction and then the BIDOUT instruction is executed.
2) The transmission data count and transmission data are written into the transmission area of the buffer memory.
3) The Q series C24 sends data by adding the control code ENQ at the beginning of the data.
   ＊ When "Sum check" is designated with GX Developer, the Q series C24 adds the sum check code calculated by internal processing to the end of the message and then transmits the message.
   When "No sum check" is designated with GX Developer, no sum check code is sent.
4) A response for the data transmission (for normal completion: ACK message; for abnormal completion: NAK message) is received.
5) The execution of the BIDOUT instruction completes with the transmission processing completion of the Q series C24.

7.2.2 Arrangement and contents of the transmission area and the transmission data

This section explains the arrangement and contents of the transmission area and the transmission data for performing data transmission using the bidirectional protocol. For details on the contents of transmission data, see Section 7.1.2 (3).

(1) Transmission area

The transmission area is a memory area for storing the data and the data count that are transmitted from the PLC CPU to the external device via the Q series C24. By default, the transmission area is assigned to addresses 400H to 5FFH (CH1 side) and 800H to 9FFH (CH2 side).



POINT

(1) The position and size of the transmission area in the buffer memory can be changed with QSCU in accordance with the specifications of the external device and the transmission data length. (See Section 8.4.5.)

(a) When changing the position and size of the transmission area in the buffer memory with QSCU, designate as follows:

1) Transmission buffer memory head address designation
Designate the starting address for the area to be used as the transmission area in the user definable area of the buffer memory.
2) Transmission buffer memory length designation
Designate by addresses the length of the area to be used as the transmission area in the user definable area of the buffer memory.

(b) If the following functions are also used when the position and size of the transmission area in the buffer memory are changed, make sure that the addresses of the transmission area do not overlap with those for the buffer memory that stores the transmission and receive data to be used by these functions.

1) MC protocol buffer memory read/write function
2) MC protocol on-demand function
3) Non procedure protocol transmission/receive function
4) Bidirectional protocol transmission/receive function

(2) Set the size of data per data transmission from the PLC CPU to the external device to be smaller than the size of the transmission data designation area in the buffer memory.

(Transmission data designation area) ≧ (Size of data portion to be sent from the PLC CPU)

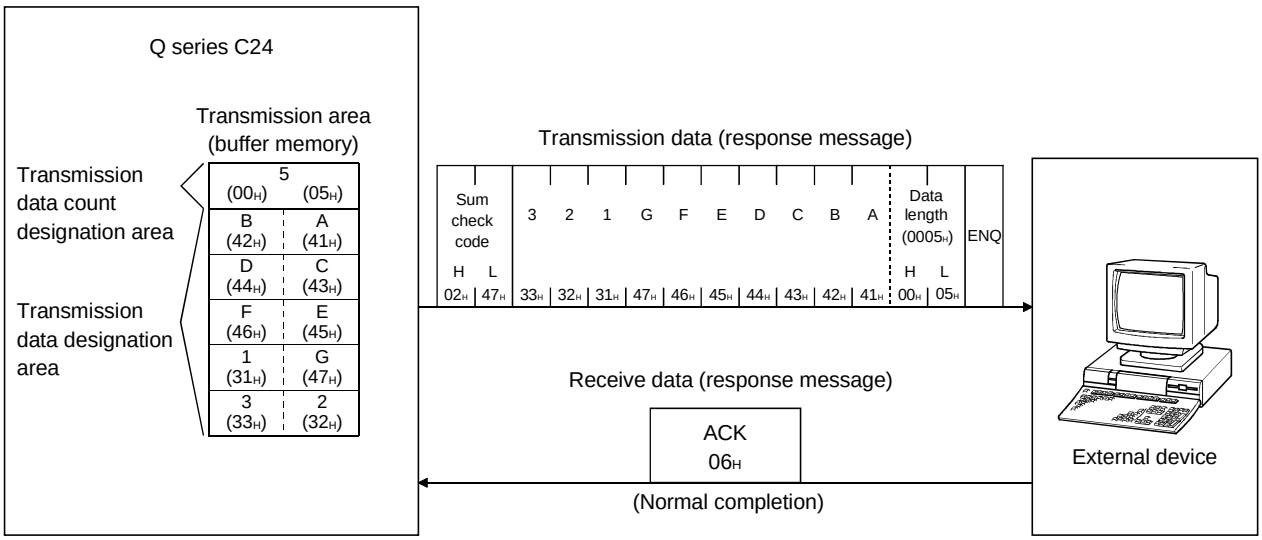
To transmit data whose size is larger than the transmission data designation area, increase the transmission area, or divide the transmission data before sending.

7 - 15

(2) Transmission data arrangement

The following example shows an arrangement of the transmission data to be sent to the external device when storing it in the transmission area.

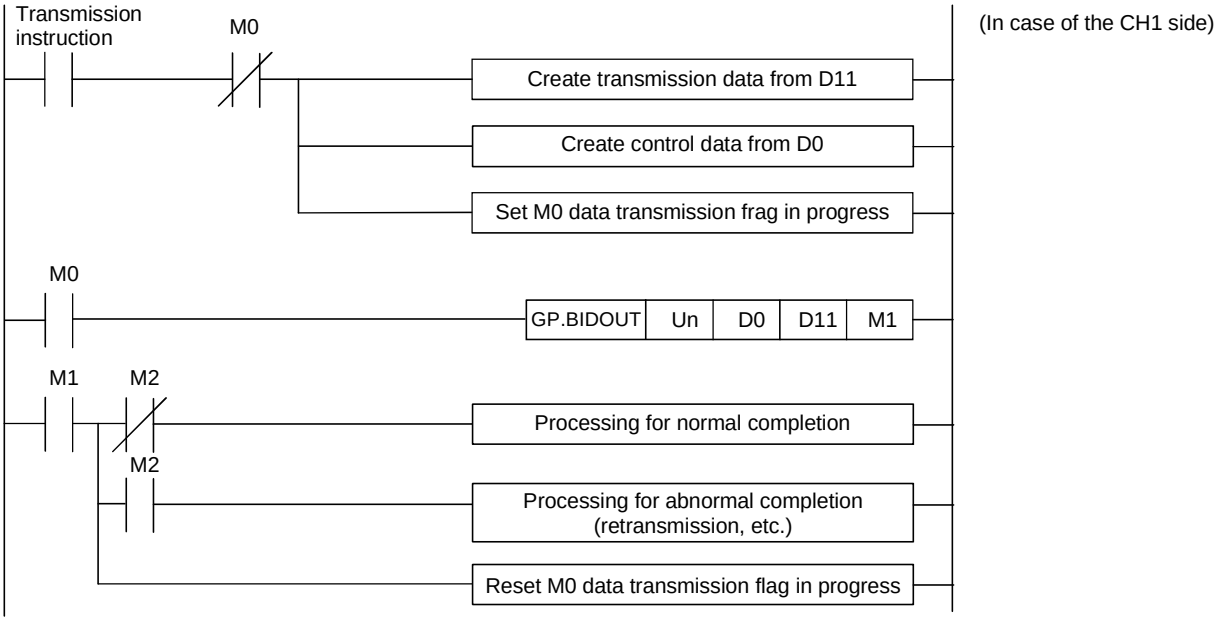
(Example) When "ABCDEFG123" is sent:

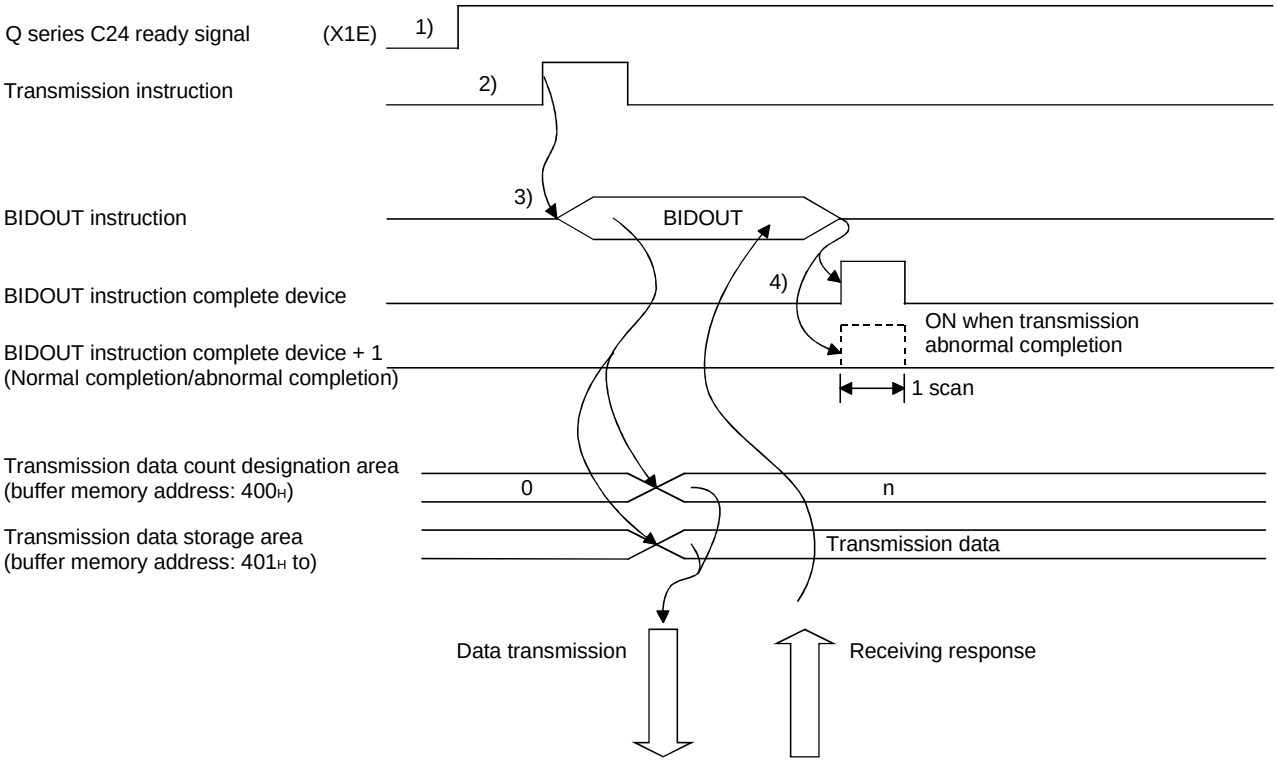


7 - 16

7.2.3 Sequence program for data transmission

A sequence program for data transmission is explained below.
For details on the BIDOUT instruction for data transmission, see Chapter 9.

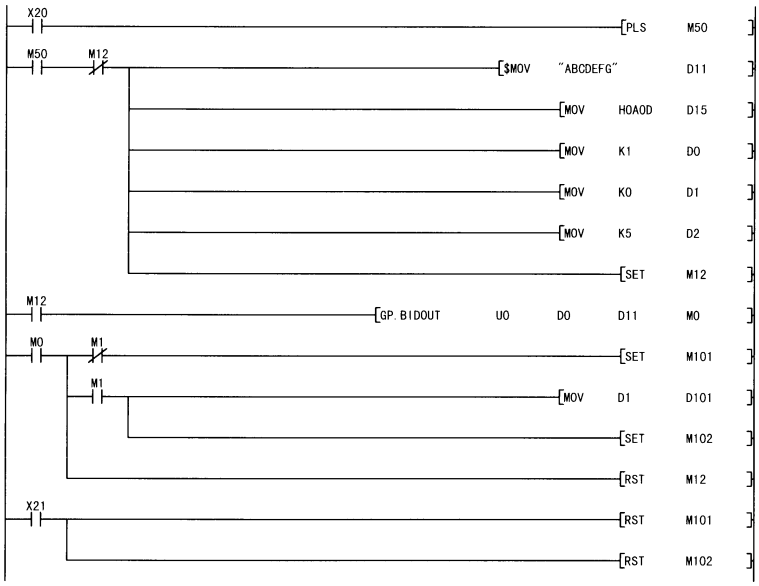


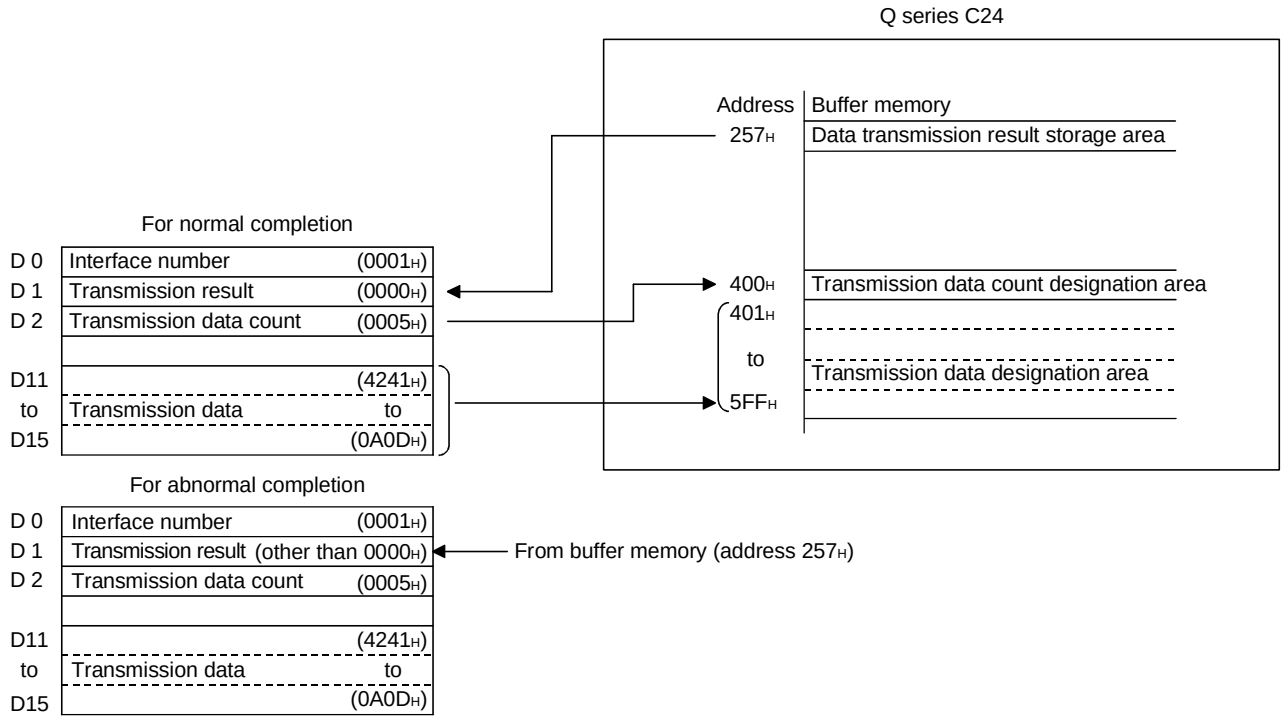


7 - 17

1) Starts the local station PLC.
   The setting values for GX Developer are stored in the Q series C24.
2) Inputs the user data transmission instruction signal.
3) Executes the BIDOUT instruction after storing the transmission data and the control data for the BIDOUT instruction in the device.
   Data is sent when the BIDOUT instruction is executed.
4) A response message for the data transmission (for normal completion: ACK message; for abnormal completion: NAK message) is received.
5) When the response is received, the Q series C24 transmission processing completes and the device that has completed the BIDOUT instruction turns ON.
   When the BIDOUT instruction ends abnormally due to the reception of an NAK message, the complete device +1 (abnormal completion signal) turns ON and the error code is stored in the control data completion status (S1+1).

(Program example)
When Q series C24 I/O signals are from X/Y00 to X/Y1F:





POINT
(1) The SPBUSY instruction is used to read the execution status when using a dedicated instruction. (See Chapter 9.)
(2) More than one BIDOUT instruction cannot be executed simultaneously. Execute the next BIDOUT instruction only after the execution of the first BIDOUT instruction is completed.

7 - 19

7.2.4 How to detect transmission errors

This section explains how to detect errors that may occur when sending data to the external device.

The following items are considered as the primary causes of errors that may occur during data transmission.

Cause of transmission error	Reference section	
A transmission error occurred because of noise.	—	
A timeout occurred for the no-reception monitoring time (timer 0).	User's Manual (Application)	Section 6.1
A timeout occurred for the response monitoring time (timer 1).		Section 6.2
A timeout occurred for the transmission monitoring time (timer 2)		Section 6.3
Data that could not be converted with the ASCII-BIN conversion was detected.		Chapter 13
Designated the transmission data count that exceeded the transmission area size.	Section 7.2.2	
Simultaneous transmissions occurred.	Section 7.3	

(1) Confirmation using the sequence program

(a) Detecting a transmission error

1) The following device and input signal turn ON.
   - BIDOUT instruction complete device + 1
   - ERR LED ON signal (XE/XF)
2) The transmission error code can be checked using the BIDOUT instruction control data ((S1) + 1).
   Or, it can be checked by reading the data transmission result storage area in the buffer memory (addresses 257H/267H).
   For details on how to check the error code contents and corrective actions, see Chapter 10.

(b) How to turn off the ERR LED and clear the error code (see Section 10.1.2)

1) To turn off only the ERR LED, write a "1" to the LED OFF request area (addresses 0H/1H) in the buffer memory.
2) To turn off the ERR LED and clear the error code, turn ON the ERR LED OFF request output signal (YE/YF).
   (Example) To perform the ERR LED OFF and the error code clear on the CH1 side:

(2) Confirmation using the module and QSCU

1) Confirmation using the display LED
   When the Q series C24 detects an error, including a reception error, the ERR LED lights up. (See Chapter 10.)
2) Confirmation using QSCU
   - The monitor function is used to check for errors. (See Sections 8.6.3 and 8.6.6.)
   - The ERR LED is turned off with the ERR LED OFF function. (See Section 8.6.10.)
3) Confirming the error code
   Use one of the following to confirm the error code.
   - QSCU monitor function (See Section 8.6.6.)
   - GX Developer buffer memory monitor function (monitors addresses 257H/267H)

7.3 Processing when Simultaneous Transmission Performed During Full-Duplex Communications

This section explains the processing when simultaneous transmissions occur in full-duplex communication.

7.3.1 Processing when simultaneous transmissions occur

This section explains the processing performed by the Q series C24 when the external device and the Q series C24 transmit at the same time during data communications using the bidirectional protocol.
Since the external device and the Q series C24 do not transmit at the same time during half-duplex communications (see User's Manual (Application) Chapter 8), this section does not have to be read.

When an external device and the Q series C24 transmit at the same time, the Q series C24 processing depends on the setting of "Simultaneous transmission data valid/invalid designation" with QSCU.

* The QSCU setting value, "Simultaneous transmission data valid/invalid designation" is stored in the following areas of the buffer memory.
  Simultaneous transmission data valid/invalid designation area (addresses: $9B_H$/$13B_H$)
  The Q series C24 communication data processing for each setting is described in Section 7.3.2.

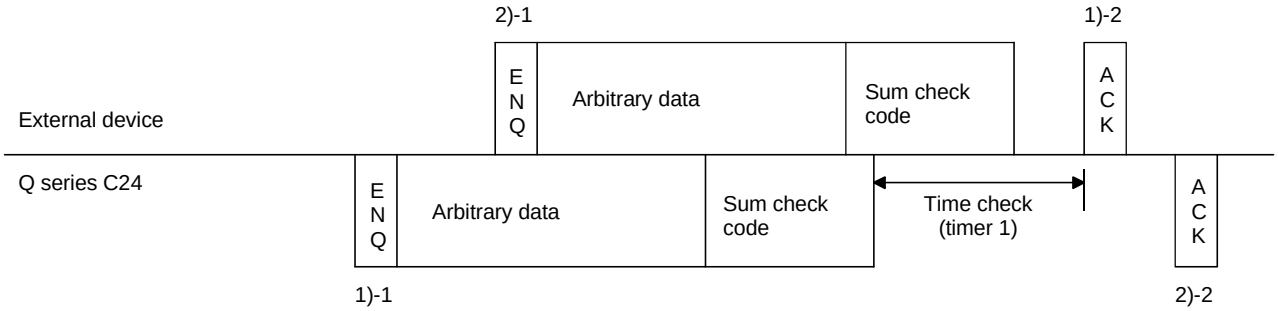
Setting contents with QSCU	Value set to buffer memory (Address $9B_H$/$13B_H$)	Q series C24 processing contents	
		Message transmit processing	Message receive processing
Transmission data: Valid Receive data: Valid	0000_H	Waits to receive the response message (1)-2) while checking time-out after data transmission (1)-1) is complete. Posts normal end or abnormal end according to whether or not the PLC CPU received a response message through the buffer memory.	Transmits a response message (2)-2) after data reception (2)-1) is complete. Posts the receive data and receive result to the PLC CPU through the buffer memory.
Transmission data: Invalid Receive data: Valid	0100_H	Posts a simultaneous transmission error to the PLC CPU through the buffer memory after data transmission (1)-1). Does not wait for a response massage (1)-2) in reply to data transmission (1)-1).	Transmits a response message (2)-2) after data reception (2)-1) is complete. Posts the receive data and receive result to the PLC CPU through the buffer memory.
Transmission data: Valid Receive data: Invalid	0001_H	Waits to receive the response message (1)-2) while checking time-out after data transmission (1)-1) is complete. Posts normal end or abnormal end according to whether or not the PLC CPU received a response message through the buffer memory.	Ignores data reception (2)-1) and discards the received data. Does not transmit a response message (2)-2). Does not inform the PLC CPU that data was received.
Transmission data: Invalid Receive data: Invalid	0101_H	Posts a simultaneous transmission error to the PLC CPU through the buffer memory after data transmission (1)-1). Does not wait to a response massage (1)-2) in reply to data transmission (1)-1).	Ignored data reception (2)-1) and discards the receive data. Does not transmit a response message (2)-2). Does not inform the PLC CPU that data was received.

( )-m) is the number showing the correspondence with the messages in the illustration shown in Section 7.3.2.

7.3.2 Communication data processing when simultaneous transmissions occur

Examples of the Q series C24 communication data processing for various settings of "Simultaneous transmission data valid/invalid designation" by QSCU are explained.

(1) Transmission: valid, reception: valid

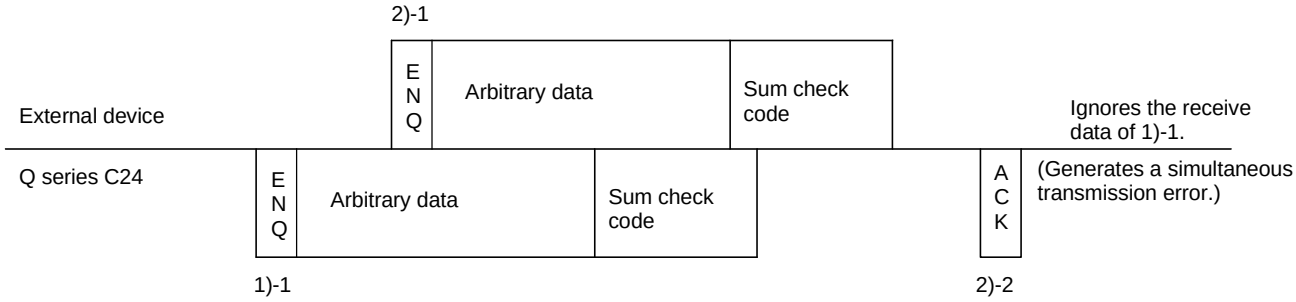


POINT

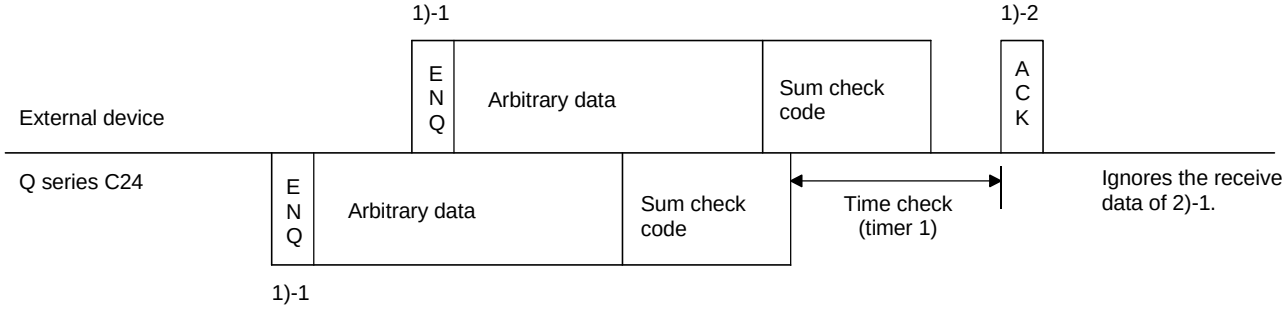
When the entire message of 2)-1 was received while transmitting the message of 1)-1 in the illustration.

- The Q series C24 outputs the receive data read request signal of 2)-1 to the PLC CPU after transmitting all 1)-1. (Turns on the X3/XA.)

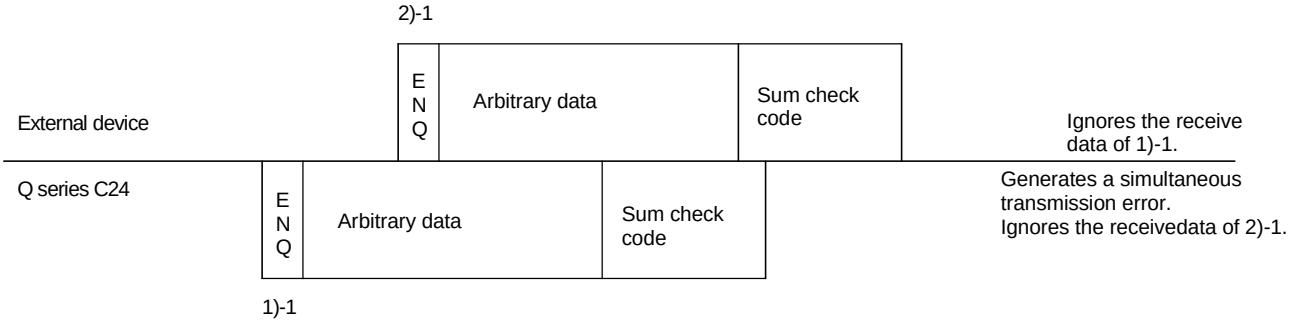
(2) Transmission: invalid, reception: valid



(3) Transmission: valid, reception: invalid



(4) Transmission: invalid, reception: invalid



REMARK

Time-check timer 1 (response monitoring time) shown in the illustration is described in Section 6.2 of User's Manual (Application).

POINT

When the transmission control (see Chapter 9 of User's Manual (Application)) is performed, and the simultaneous transmission data valid/invalid designation sets that the receive data is valid and transmission data is valid, the Q series C24 performs message transmission and message reception processing as described below.

During message transmission processing, time check by timer 1 (response monitoring time) is performed.

1) Message transmission (1)-1 in the illustration)
   - If the Q series C24 receives a terminate transmission request (DC3 received/DSR signal OFF) from the external device during message transmission, it terminates data transmission.
   - When the Q series C24 receives the ready to send signal (DC1 received/DSR signal ON), it restarts data transmission.
2) Message reception
   - If the Q series C24 cannot send a response message to the external device in response to message reception because the external device issued a terminate transmission request (DC3 received/DSR signal OFF), it transmits the response message after it receives the ready to send signal (DC1 received/DSR signal ON) from the external device.

7.4 Data Communications Precautions

The following shows the precautions when performing data communications using the bidirectional protocol.

(1) When the transmission sequence is in the initial status, it indicates that data transmission and reception processing has not been started.
The Q series C24 transmission sequence is initialized in the following cases.
- The power is turned on, the CPU is reset.
- When operating, or the mode is switched.
- When a response message (ACK, NAK, etc.) was received in reply to data transmission.
- When a response message (ACK, NAK, etc.) was transmitted in reply to data reception.
- When the CD signal was turned off during data communications using Check CD terminal in full-duplex communications through the RS-232 interface.

(2) As a data transmission procedure, data transmission from the external device or the Q series C24 should be performed after an response for the immediately preceding data transmission has been received.

(3) The external device and PLC CPU must agree so that the units of the data length (word count/byte count) in the message to be transmitted and received is the same.
The PLC CPU units can be set using the QSCU word/byte units designation.
Make the length of the data area in the message to be transmitted and received the size of the Q series C24 buffer memory transmission data designation area and receive data storage area, or less.

(4) NAK code response
1) Response from the Q series C24 to external device
After the error detection message reception complete, it transmits the NAK code to the external device.
2) Response from external device to the Q series C24
Transmit the error code (22_H to $5F_H$) immediately after the NAK response.

POINT

(1) Perform error processing according to the error code received immediately after the NAK message at the device that received NAK as the response message after data transmission.
Chapter 10 shows the error codes that are transmitted from the Q series C24.

(2) If the Q series C24 receives an NAK response while transmitting data to an external device, it completes data transmission, then reads the NAK, perform abnormal completion.

(3) If the Q series C24 detects an error while receiving data, it ignores the receive data corresponding to the data length.
If the data length is abnormal, the Q series C24 ignores all the data up to the receive message head data (ENQ, etc.) received thereafter.

(5) External device time-out check

When checking time-out up to reception of the response message at the external device during data transmission from external device to the Q series C24, make the time-out time the time shown below, or longer.

(PLC CPU maximum scan time × 2) + 100 ms

(6) External device framing error

When nothing is transmitted from the Q series C24 to the external device though the RS-422 or RS-422/485 interface, a framing error may be generated in the external device.

Make the external device skip the data up to transmission of the head data (ENQ, NAK, etc.) of the message from the Q series C24.

Before communicating data through the RS-422/485 interface, check Q series C24 specifications given in Section 3.3.

(7) Data bit settings

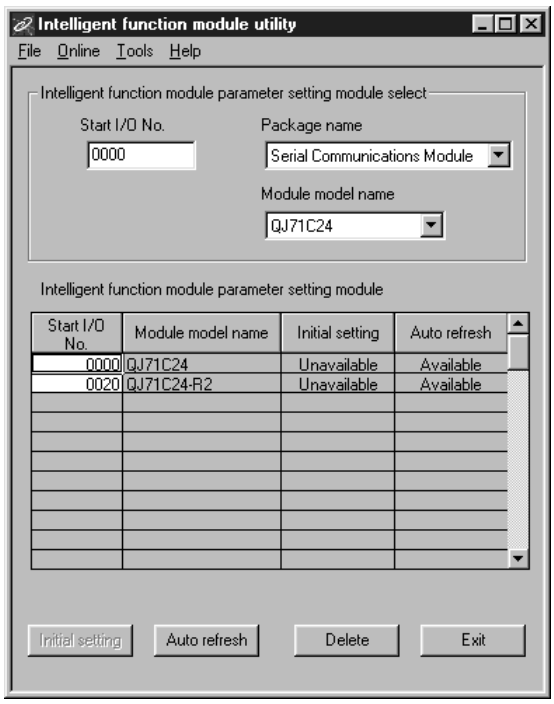
When adding a sum check code to a message, set the data bits to 8 bits using the transmission setting of the GX Developer.

For more details on the data bit settings, see Section 4.5.

8 UTILITY PACKAGE (SW0D5C-QSCU-E)

The utility package for the Q series C24 (hereinafter referred to as "QSCU") have been designed to facilitate user-friendly the Q series C24 operations such as initial settings and monitoring using the dedicated screens, so that the user is free from any concerns for the I/O signals and buffer memory.

The utility package can also be used together with the GX Simulator (SWnD5□-LLT-E).



8.1 Functions Available with Utility Package

The following table lists the utility package function.
(○ : indicates that the setting is valid with the applicable protocol.)

Function			MC	Non procedure protocol	Bidirectional protocol	Explanation page	Remarks
Auto refresh setting		Refresh the Q series C24's error codes and set devices on the PLC CPU side.	○	○	○	Section 4.6	Can be used via online operation. Can be used via offline operation.
User frame		Register the user frame in the flash ROM.	○	○	—	Section 8.4.1	
Data for modem initialization		Register the data for modem initialization in the flash ROM.	○	○	○	Section 8.4.2	
Data for modem connection		Register the data for model connection in the flash ROM.	○	○	○	Section 8.4.3	
Modem function system setting		Register the system setting values for model function in the flash ROM.	○	○	○	Section 8.4.4	
System setting	CHn Transmission control and others system setting	Set the transmission specifications with the other device. DTR/DSR control, DC code control, communication method, data communication monitoring timer value, etc.	○	○	○	Section 8.4.5	
	CHn MC protocol system setting	Assign the buffer memory for on-demand function, set the user frame number, etc.	○	—	—	Section 8.4.6	
	CHn Non procedure system setting	Assign the buffer memory needed to perform data communication using the non procedure protocol, and change the setting values, etc.	—	○	—	Section 8.4.7	
	CHn Bidirectional system setting	Assign the buffer memory needed to perform data communication using the bidirectional protocol, and change the setting values, etc.	—	—	○	Section 8.4.8	
	CHn PLC CPU monitoring system setting	Set the PLC CPU monitoring function.	○	○	—	Section 8.4.9	
	CHn Transmission user frame No. designation system setting	Set the user frame number to be transmitted, etc.	—	○	—	Section 8.4.10	
System setting default		Reset the setting values in the buffer memory to their default values.	○	○	○	Section 8.4.11	Can be used only via online operation.
System setting write		Write the setting values in the buffer memory to the flash ROM.	○	○	○	Section 8.4.11	
Flash ROM write allow/prohibit designation		Set whether to allow or prohibit writing to the flash ROM.	—	—	—	Section 8.4.12	
X · Y monitor/test		Perform the monitoring/testing of I/O signals to/from the PLC CPU.	○	○	○	Section 8.6.1	
Modem function monitor/test		Monitor the execution status of the modem function.	○	○	○	Section 8.6.2	
Monitor	CHn Transmission control and others monitor	Monitor the status of interface control signals, values set from the GX Developer, etc.	○	○	○	Section 8.6.3	
	CHn MC protocol monitor	Monitor the data communication result, I/O signal status, and setting values in the buffer memory.	○	—	—	Section 8.6.4	
	CHn Non procedure monitor/test		—	○	—	Section 8.6.5	
	CHn Bidirectional monitor		—	—	○	Section 8.6.6	
	CHn PLC CPU monitoring monitor	Monitor the setting values and operating status of the PLC CPU monitoring function.	○	○	—	Section 8.6.7	
	CHn User frame No. designation monitor for transmission	Monitor the setting value for user frame to be transmitted.	○	○	—	Section8.6.8	
Monitor others		Monitor the data reception result, error occurrence status, etc.	○	○	○	Section 8.6.9	
ERR LED off		Turn off the ERR LEDs on the front face of the module.	○	○	○	Section 8.6.10	
Non procedure protocol receive data clear		Clear the currently received data.	—	○	—	Section 8.7	

8 - 2

8.2 Installing and Uninstalling Utility Package

For installing and uninstalling utility package, see the GX Developer Operating Manual (Startup).

8.2.1 Usage precautions

The following describes the precautions on using the utility package:

(1) Important safety information

Since the utility package is add-in software for GX Developer, read "Safety Precautions" and the basic operating procedures contained in GX Developer's Operating Manual.

(2) About installation

The SW0D5C-QSCU-E is an add-in package for SW4D5C-GPPW-E (V) or later versions.

Therefore, install SW0D5C-QSCU-E in a peripheral device in which SW4D5C-GPPW-E (V) or a later version has been installed.

(3) About the license key floppy disk

(a) The license key floppy disk is necessary to install and uninstall the SW0D5C-QSCU-E software.
Installation and uninstallation is impossible without the license key floppy disk.

(b) Use the license key floppy disk that was purchased along with the software as it is (a copy of the license key floppy disk cannot be used).

(c) Store the license key floppy disk carefully.

POINT

Do not perform any of the following operations on the license floppy disk.

* The license key floppy disk will be rendered useless if any of the following happens.
  - Formatting the floppy disk.
  - Writing a file to the floppy disk.
  - Copying a file in the floppy disk (copying to another drive, copying from another drive)
  - Deleting, changing names, and changing attributes of any of the files in the floppy disk.
  - Running an analysis tool (e.g. SCANDISK) on the floppy disk.

(4) About display screen errors while using the intelligent function module utility

There may be cases in which the screen will not properly display while the intelligent function module utility is being used, due to a lack of system resources. If this occurs, close the intelligent function module utility first and then GX Developer (program, comments, etc.) and other applications. Then, restart GX Developer and the intelligent function module utility.

(5) To start the intelligent function module utility

(a) In GX Developer, select "QCPU (Q mode)" for the PLC series and specify the project.
If anything other than "QCPU (Q mode)" is selected for the PLC series, or if the project is not specified, the intelligent function module utility will not start.

(b) Multiple intelligent function module utilities can be started.
However, the [Open file]/[Save file] intelligent function module's parameter operations can only be performed by a single intelligent function module utility. Other intelligent function module utilities can perform the [Monitor/Test] operation only.

(6) How to change screens when two or more intelligent function module utilities are started

When two or more intelligent function module utility screens cannot be displayed side by side, use the task bar to change the intelligent function module utility screen so that it is displayed on top of other screens.

8.2.2 Operating environment

This section explains the operating environment of the SW0D5C-QSCU-E.

Item		Peripheral devices
Installation (Add-in) ＊1		Add-in to SW4D5-GPPW-E (English version) or later
CPU		Pentium 133 MHz or faster recommended
Memory		32 MB or more recommended
Free space	For installation (HD)	Minimum 3 MB
	For execution (Virtual memory)	Minimum 10 MB
Display		800 × 600 pixels or higher resolution
Operating system (OS)		Microsoft® Windows® 95 operating system (English version), Microsoft® Windows® 98 operating system (English version), Microsoft® Windows® NT Workstation 4.0 operating system (English version)

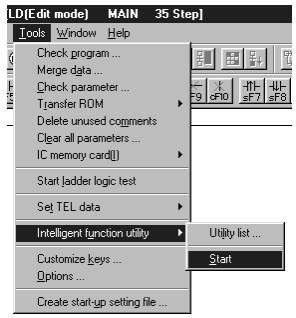
＊1: Please install SWnD5C-GPPW (n is 4 or greater) and SW0D5C-QSCU-E with a software package of the same language.
SWnD5C-GPPW (Japanese version) cannot be installed with SW0D5C-QSCU-E (English version), and SWnD5C-GPPW-E (English version) cannot be installed with SW0D5C-QSCU (Japanese version).

＊2: SW0D5C-QSCU-E cannot add-in to SW3D5C-GPPW-E and SW3D5F-GPPW or before.

8.3 Explanation of Utility Package Operation

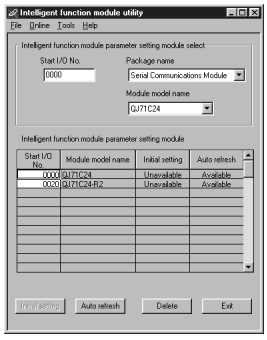
8.3.1 Operation overview

GX Developer screen



[Tools] – [Intelligent function utility] – [Start]

Intelligent Function Module
Select Parameter Setting Module screen



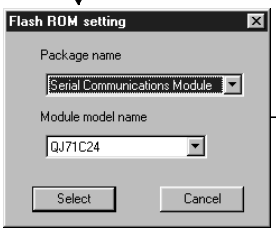
See Section 8.3.2

When used via online operation → 1) Go to next page

When auto refresh is set → 2) Go to next page

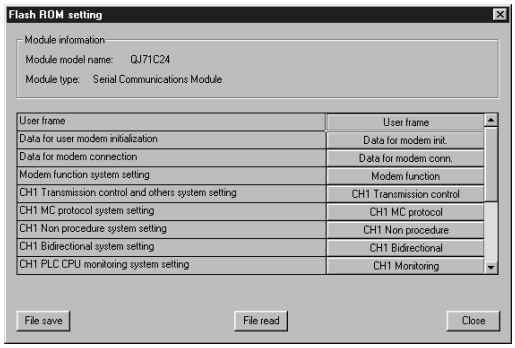
When used via offline operation

Select [Tools] – [Flash ROM stting] from the menu bar.



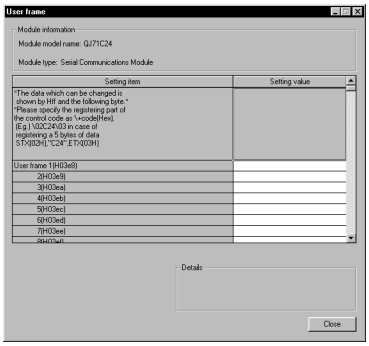
Select the package name and module model name.

Flash ROM settings screen



See Section 8.4

To each setting screen



See Sections 8.4.1 through 8.4.10

POINT

The following settings must be performed before starting the intelligent function module utility:

- Set the project using the GX Developer
- Set "QCPU (Q mode)" for the PC series.

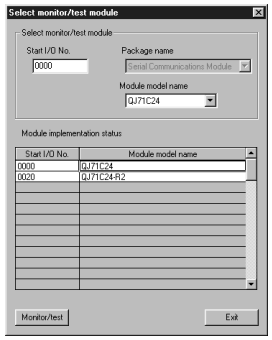
POINT

The various setting values to be registered in the Q series C24's flash ROM can be saved in a file of the PC via offline operation. Use online operation to write system setting values to the Q series C24.

1) When using online operation

Select [Online] – [Monitor/test] from the menu bar.

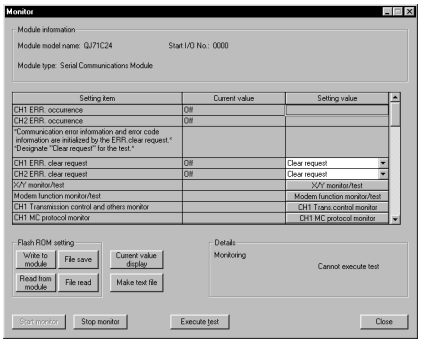
Select monitor/test module screen



Monitor/test

Select the parameter setting module for monitor/test.

Monitor/test screen



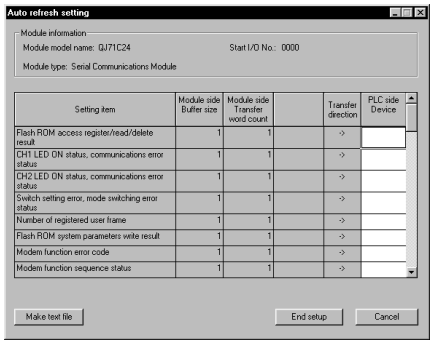
See Section 8.4
See Section 8.6

2) When setting auto refresh

Auto refresh

Enter "Start I/O No.," then select "Package name" and "Module model name."

Auto refresh screen



See Screen 4.6

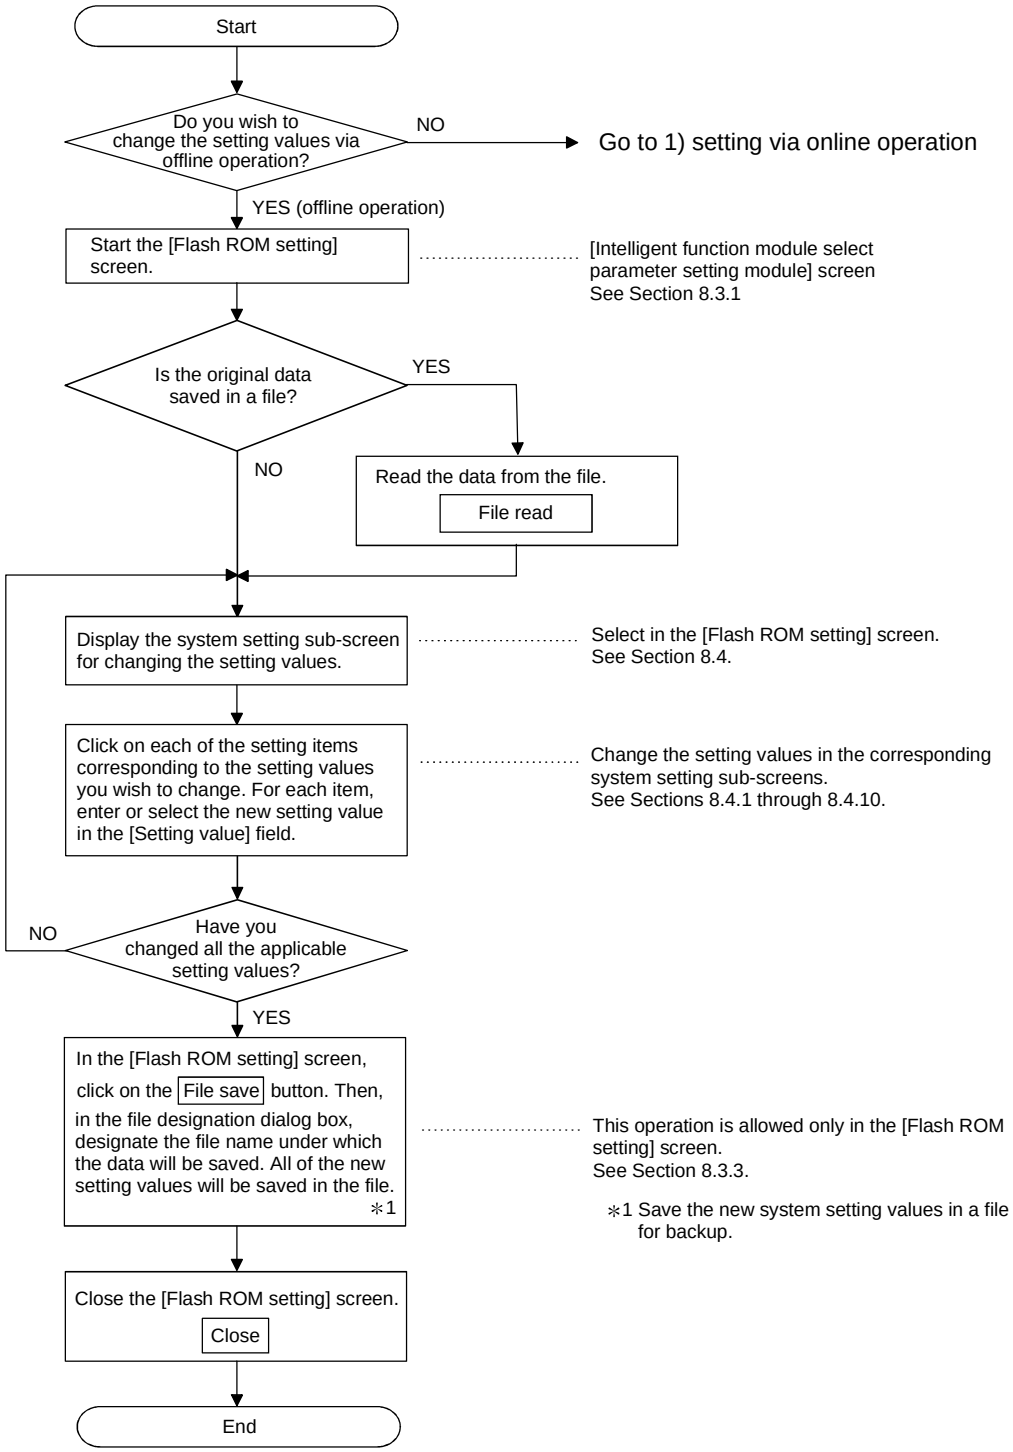
POINT

(1) When the setting operation is complete in each system setting screen, register the system setting data in the flash ROM, then restart the PLC CPU resume data transmission.

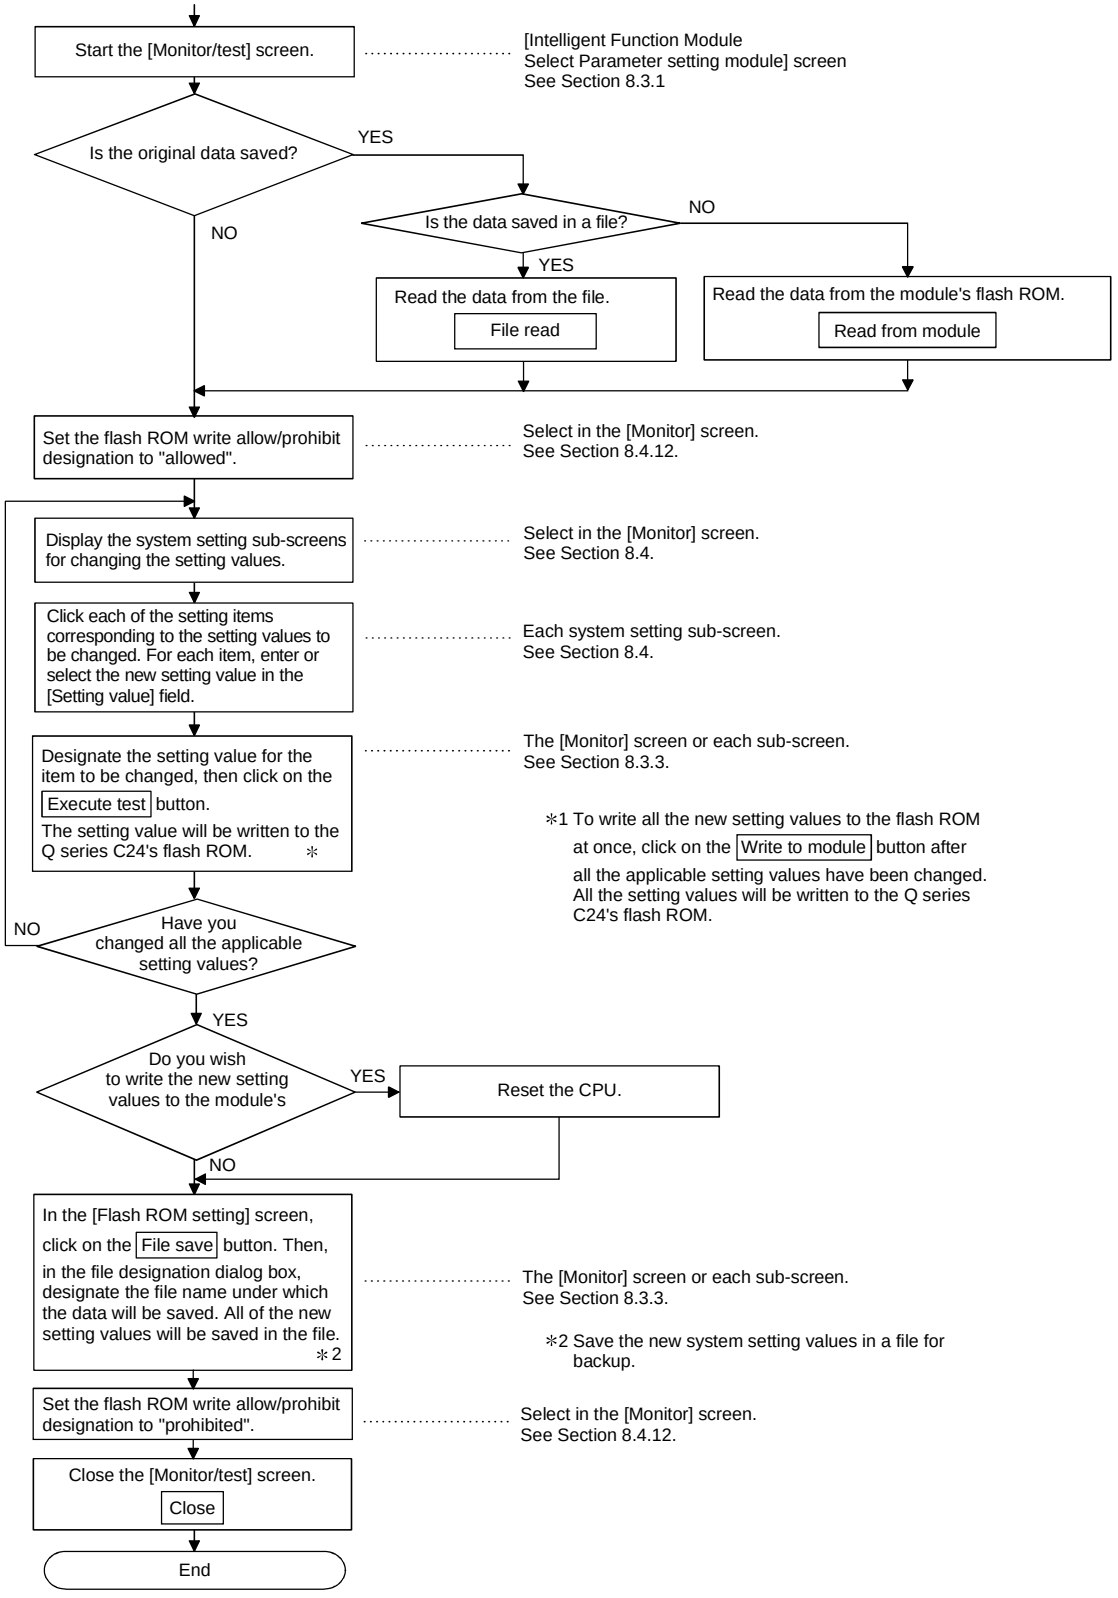
(2) With the Q series C24, monitoring, testing, and reading/writing of setting values can be performed via online operation.

REMARK

The following diagram illustrates the overview of a procedure in which the QSCU is used to change the system setting values of the Q series C24 and save the new values to a file or write them to the Q series C24's flash ROM.



1) (Online operation)



8.3.2 Starting the intelligent function module utility (displaying the [select parameter setting module] screen)

[Purpose]

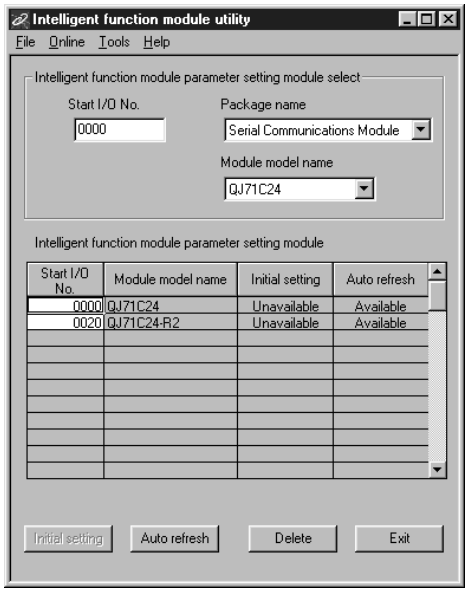
Start the intelligent function module utility from the GX Developer, and display the module selection screen for the intelligent function module utility parameter setting. The screens that perform system setting, auto refresh setting, and monitoring/testing for the Q series C24 can be started from this module selection screen.

POINT
To start the Intelligent function module utility, a project created with the GX Developer whose PLC series is set as "QCPU (Q mode)" is required.

[Startup procedure]

[Tools] → [Intelligent function module utility] → [Start]

[Setting screen]



- Start I/O No.
  Enter the start I/O number for the applicable the Q series C24 using a hexadecimal expression.
- Package name
  Select [Serial communication module].
- Module model name
  Select the module model name of the applicable the Q series C24.
- Intelligent function module parameter setting module
  The modules for which parameters are set with the intelligent function module utility are displayed.
  Select the target module of your operation.

* It is not necessary to select [Intelligent function module, select parameter setting module] to perform monitor/test operation.

[Explanation of items]

(1) How to start each screen

(a) Starting the flash ROM setting screen
[Tools] → [Flash ROM setting] → "Package name" → "Module model Name" → Select

(b) Starting auto refresh settings
"Start I/O No." → "Package name" → "Module model name" → Auto refresh

(c) Monitor/test module selection screen
[Online] → [Monitor/test] → "Module selection" → Monitor/test

(2) Command buttons

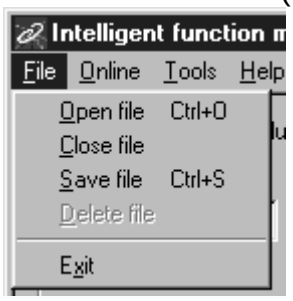
Initial settings : Cannot be selected.

Auto refresh : Starts the auto refresh setting screen.

Delete : Deletes the initial settings and auto refresh settings.

Exit : Closes the parameter setting module selection screen.

(3) Menu bar



(a) File items

The intelligent function module parameters (data for auto refresh) for the project opened by GX Developer can be processed in file operation.

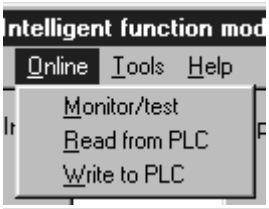
[Open file] : Reads the parameter file.

[Close file] : Closes the parameter file. If revisions are made, the dialog box asking whether to save the file appears.

[Save file] : Saves the parameter file.

[Delete file] : Deletes the parameter file.

[Exit] : Closes the parameter setting module selection screen.

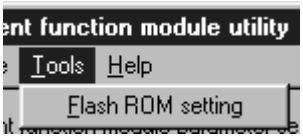


(b) Online items

[Monitor/test] : Starts the monitor/test module selection screen.

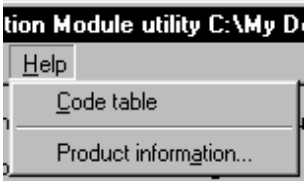
[Read from PLC] : Reads the intelligent function module parameters from the CPU module.

[Write to PLC] : Writes the intelligent function module parameters to the CPU module.



(c) Tool items

[Flash ROM setting] : Starts the flash ROM setting screen.



(d) Help items

[Code list] : Displays the ASCII code list. Use this list as reference when setting data.

[Product information] : Displays the version information of the intelligent function module utility.

POINT

(1) Saving the intelligent function module parameter files

Since files cannot be saved using the GX Developer project save operation, save the files on the module selection screen for parameter setting described above.

(2) Reading from and writing to PLC operations for the intelligent function module parameters using GX Developer

(a) After the intelligent function module parameters are saved in a file, they can be read from and written into the PLC.

(b) Set the target PLC using the GX Developer [Online] → [Transfer setup]. Only use the control PLC for the Q series C24 to write the intelligent function module parameters for a multiple PLC system to the PLC.

(c) Use the GX Developer for PLC reading or PLC writing the intelligent function module parameters at the remote I/O station. QSCU can not be used.

8.3.3 Performing common utility operations

This section explains how to perform the common operations in the data setting, auto refresh setting and monitor/test screens.

(1) Available Control Keys

The following table lists the special keys that can be used during operation of utility and their applications:

Name of key	Application
Esc	Cancels a newly entered value when entering data in a cell. Closes the window.
Tab	Moves between the controls in the window.
Ctrl	Used in conjunction with the mouse to select multiple cells in the selection test.
Delete	When a cell is selected, clears all set data.
Back space	Deletes the character where the cursor is positioned.
↑ ↓ ← →	Moves the cursor.
Page up	Moves the cursor one page up.
Page Down	Moves the cursor one page down.
Enter	Confirms the value entered in the cell.

(2) Operation Command Buttons

Current value display : Displays the current value of the selected item.

Make text file : Creates a text file (TXT format) under the specified file name and saves to it the contents currently displayed on the screen.

Start monitor : Starts monitoring of the current value field.

Stop monitor : Stops monitoring of the current value field.

Execute test : Registers the system setting data of the selected item in the flash ROM. ∗1

To apply Execute test to multiple items simultaneously, set the data for the corresponding items, select the multiple items while pressing down Ctrl, then click Execute test.

∗1 The settings for "receive data clear request" and "flash ROM write allow/prohibit designation" are written to the buffer memory.

Write to module : Registers all system setting data for the Q series C24 in the flash ROM.

Read from module : Reads all system setting data for the Q series C24 from the flash ROM.

File save	: Saves all system setting data for the Q series C24 to the designated file (extension: UMD).
File read	: Reads all system setting data for the Q series C24 from the designated file (extension: UMD).
Close	: Closes the currently displayed screen and returns to the previously displayed screen.
End setup	: Saves/writes the system setting data, closes the current screen, and returns to the previously displayed screen. * With offline operation, only [File save] and [File read] are enabled.

POINT

(1) When the setting operation is complete in each system setting screen, register the system setting data in the flash ROM, then restart the PLC CPU to resume data transmission.

(2) If two or more intelligent function module utility package are running, perform each operation after selecting the target utility package from the task bar and making it active.

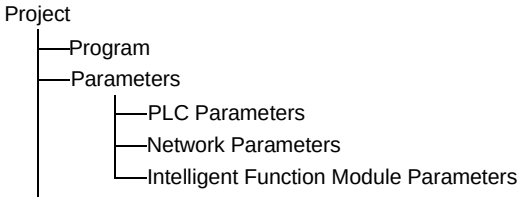
(3) When the menu screen for system registration to flash ROM (see Section 8.4) is closed, all the system setting data will be cleared. Before closing the screen, write the data to the module (enabled only via online operation) or save it to a file.

(3) Data/file to be created with utility package

The data and files shown below that are created with utility package are also used by GX Developer operation. Figure 8.1 shows an operation used to create data with utility package.

<Intelligent function module parameters>

(a) This data is created with the auto refresh settings, and stored in the intelligent function module parameter file of the project to be created using GX Developer.



(b) Steps 1) to 3) shown in Figure 8.1 are performed using the following operations.

1) Operating from GX Developer.
[Project] → [Open existing project] / [Save project] / [Save project as]
2) Operating from the utility parameter setting module selection screen.
[File] → [File read] / [File save]
3) Operating from the GX Developer.
[Online] → [Read from PLC / [Write to PLC] → "Intelligent function module parameters"
Or, operate from the utility parameter setting module selection screen.
[Online] → [Read from PLC] / [Write to PLC]

<Flash ROM data>

(a) The data set in [Flash ROM setting] can be saved in the desired directory separately from the GX Developer project.

(b) Operations 4) and 5) shown in Figure 8.1 are performed as follows:

4) This operation can be performed from the [Flash ROM setting] screen or [Monitor/test] screen.
[Flash ROM setting] screen → [File read]/[File save]
[Monitor/test] screen → [File read]/[File save]

5) This operation can be performed from the [Monitor/Test] screen of the utility.
[Monitor/test] screen → [Read from module]/[Write to module]

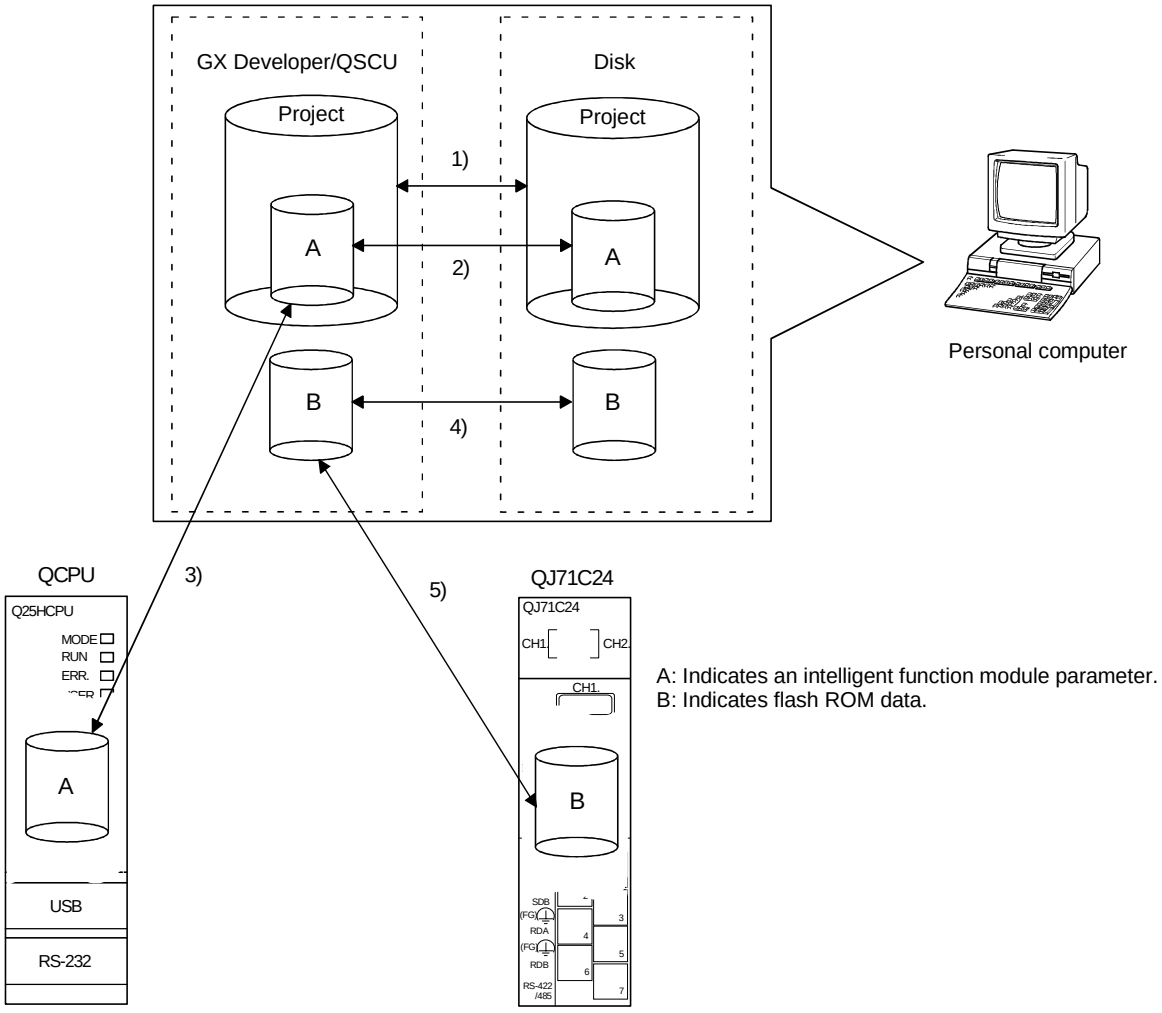


Figure 8.1 Correlation chart for data created by the utility package

8.4 System Registration to Flash ROM

[Purpose]

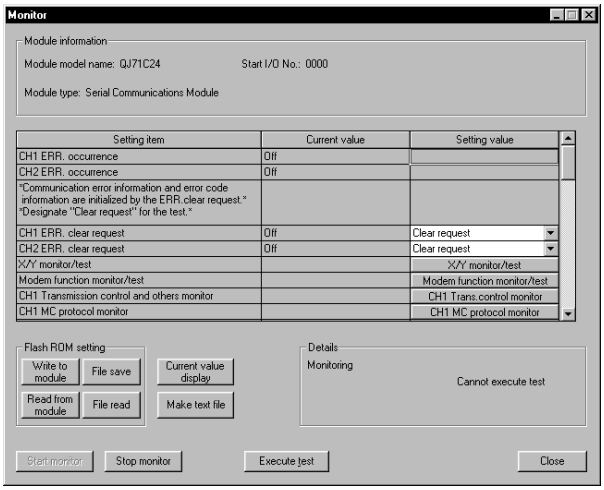
Display the menu screen for flash ROM registration, which is used to change the initial values set in the Q series C24's buffer memory.

[Startup procedure]

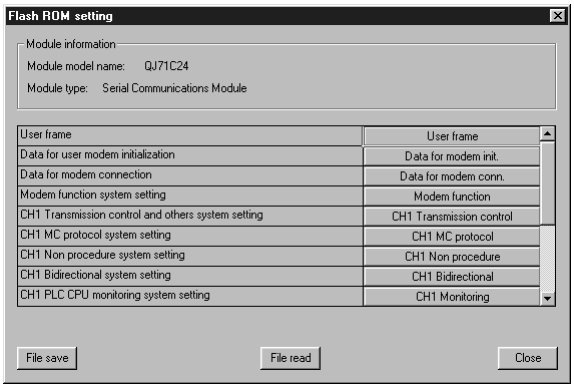
- Online operation
  - ∗ Startup from Intelligent function module utility
    (GX Developer (SW4D5C-GPPW-E or later))
    [Online] → [Monitor/test] → "Select monitor/test module" → Monitor/test → [Monitor] screen
  - ∗ Startup from the system monitor (GX Developer (SW6D5C-GPPW-E)).
    [GX Developer] → [Diagnostics] → [System Monitor] → "Select the Q series C24 by installation status" → Diagnostics... → [Monitor] screen
- Offline operation
  [Tools] → Flash ROM setting → [Flash ROM setting] screen

[Setting screen]

Screen displayed during online operation (∗1)



Screen displayed during offline operation



∗1 The selection menus for system setting/registration are displayed by scrolling on the [Monitor] screen during online operation.
The selection buttons pertaining to flash ROM registration are displayed in blue on the screen.

[Setting Items]

The following table shows the selection menus for system setting/registration to be displayed:

Function	Section	Remarks
User frame registration	Section 8.4.1	Can be used via online operation. Can be used via offline operation.
Data for modem initialization registration	Section 8.4.2	
Data for modem connection registration	Section 8.4.3	
Modem function system setting	Section 8.4.4	
Transmission control and others system setting	Section 8.4.5	
MC protocol system setting	Section 8.4.6	
Non procedure system setting	Section 8.4.7	
Bidirectional system setting	Section 8.4.8	
PLC CPU monitoring system setting	Section 8.4.9	
Transmission user frame No. designation system setting	Section 8.4.10	
Resetting buffer memory/flash ROM setting values to default values	Section 8.4.11	Can be used only via online operation.
Flash ROM write allow/prohibit setting	Section 8.4.12	

POINT

(1) The User's Manual (Basic) and QSCU's Help function provide the code list. Use this list as a reference.

(2) The values set in the respective setting screens explained in Section 8.4 can be written to the Q series C24 module (via online operation only) or saved to a file.

(3) Perform the following operations in advance to enable the registration of setting values in the flash ROM:
   (a) Switch setting using the GX Developer (see Section 4.5.2)
   Set "Setting change" under [Transmission settings] to "Enable" for both the CH1 and CH2 sides.
   (b) Setting using QSCU (see Section 8.4.12)
   Set the flash ROM write allow/prohibit designation to "Allowed".

(4) Some system setting screens have a pair of screens: one for CH1 and the other for CH2. Please note that the explanations given in Section 8.4.1 and thereafter apply to the online operations performed in the CH1 screens.
The setting items are the same between CH1 and CH2, but different buffer memory addresses are used to store the setting values. The respective addresses are indicated as follows where applicable.
(Left side: address for the CH1 side, right side: address for the CH2 side)

Setting item	Setting value storage buffer memory address	Reference section containing detailed explanation
DTR/DC control designation	93H/133H	Chapter 7 of User's Manual (Application)

(5) When a multiple PLC system is employed, QSCU should be connected to the control PLC of the Q series C24, and the system setting data register in the flash ROM.
It is not possible to set target PLC to multiple PLC setting of "Transfer setup" of GX Developer and register the system setting data in the flash ROM.

8.4.1 User frame registration

[Purpose]

Register the user frame used in the following functions:

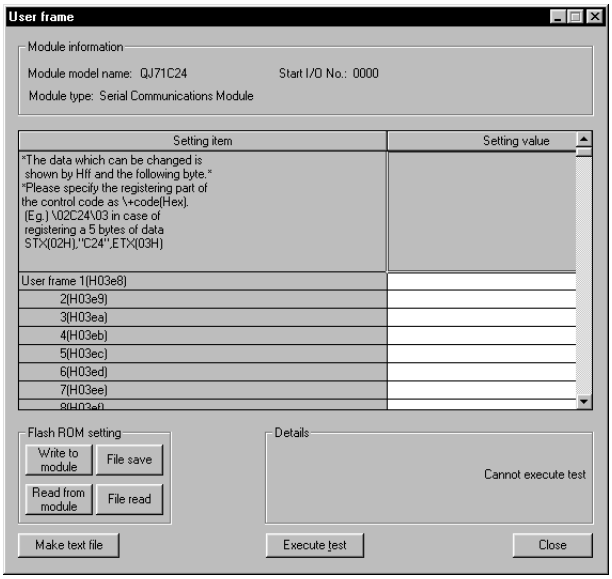
- On-demand function using the MC protocol.
- Data transmission/receive function using the non procedure protocol.

[Startup procedure]

- Online operation
  [Monitor] screen → User frame

- Offline operation
  [Flash ROM setting] screen → User frame

[Setting screen]



[Setting item]

Setting item	Setting value storage buffer memory address	Reference section containing detailed explanation
User frame 1 to 200	—	Chapter 9 of User's Manual (Application)

REMARK

Use \ + code to specify hexadecimal numbers in the control code registration field if QSCU is used for registering a user frame.

(Example) To register the 5 bytes of data, STX (02_H), "C24," and ETX (03_H), specify the following:
\02C24\03

8.4.2 Data for modem initialization registration

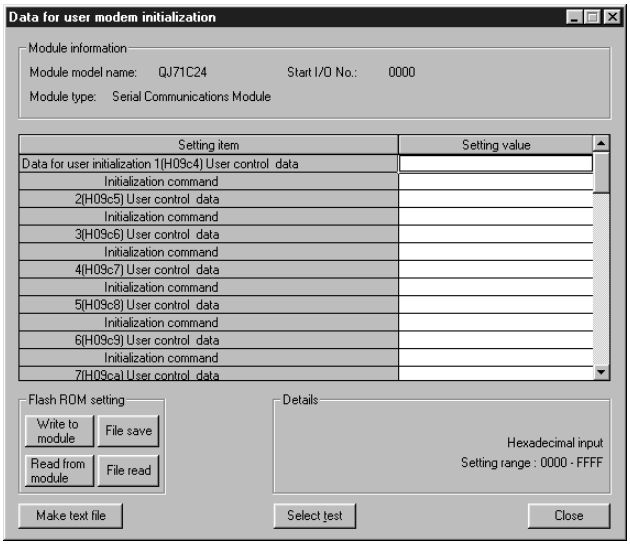
[Purpose]

Register the data for initializing the modem connected to the Q series C24.

[Startup procedure]

- Online operation
  [Monitor] screen → Data for user modem initialization
- Offline operation
  [Flash ROM setting] screen → Data for user modem initialization

[Setting screen]



[Setting item]

Setting item	Setting value storage buffer memory address	Reference section containing detailed explanation
Data for user initialization 1 to 30 User control data	—	Chapter 3 of User's Manual (Application)
Data for user initialization 1 to 30 Initialization command		

8.4.3 Data for modem connection registration

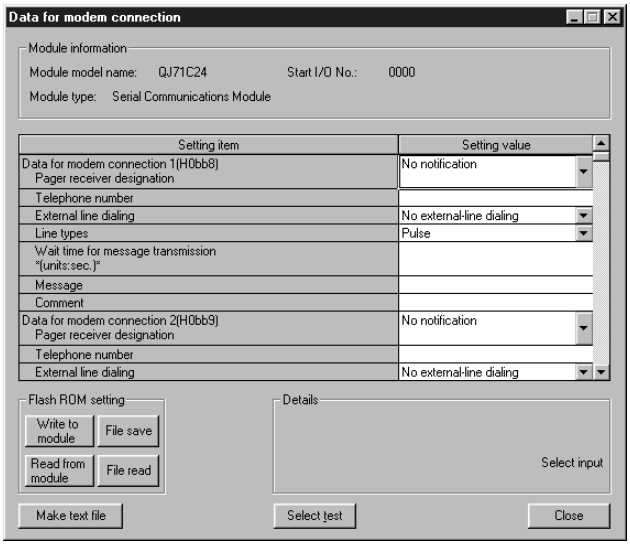
[Purpose]

For data communication and notification using the modem function, register the data for connection with external devices.

[Startup procedure]

- Online operation
  [Monitor] screen → Data for modem connection
- Offline operation
  [Flash ROM setting] screen → Data for modem connection

[Setting screen]



[Setting items]

Setting item		Setting value storage buffer memory address	Reference section containing detailed explanation
Data for modem connection 1 to 30	Pager receiver designation	—	Chapter 3 of User's Manual (Application)
	Telephone number		
	External line dialing		
	Line types		
	Wait time for message transmission units: s		
	Message		
	Comment		

8.4.4 Modem function system setting/registration

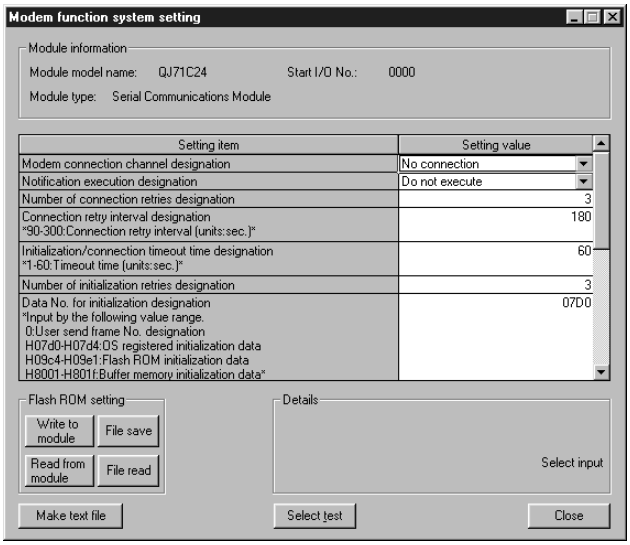
[Purpose]

For data communication using the modem function, register system setting values.

[Startup procedure]

- Online operation
  [Monitor] screen → Modem function system setting
- Offline operation
  [Flash ROM setting] screen → Modem function system setting

[Setting screen]



[Setting items]

Setting item	Setting value storage buffer memory address	Reference section containing detailed explanation
Modem connection channel designation	2EH	Chapter 3 of User's Manual (Application)
Notification execution designation	2FH	
Number of connection retries designation	30H	
Connection retry interval designation ✻ units: s ✻	31H	
Initialization/connection timeout time designation ✻ units: s ✻	32H	
Number of initialization retries designation	33H	
Data No. for initialization designation	34H	
Data No. for connection designation	35H	
GX Developer connection designation	36H	
No-communication interval time designation ✻ units: min ✻	37H	
RS · CS control yes/no designation	38H	
Modem initialization time DR signal valid/invalid designation	2008H	
Wait time of notification ✻ units: s ✻	200AH	
Circuit disconnect wait time (PLC CPU watch use) ✻ units: s ✻	200EH	
Remote password mismatch notification count designation	200CH	
Remote password mismatch notification accumulated count designation	200DH	

8.4.5 Transmission control and others system settings

[Purpose]

For data communication with external devices, register system setting values for the transmission control method, monitoring time, and buffer memory assignment.

[Startup procedure]

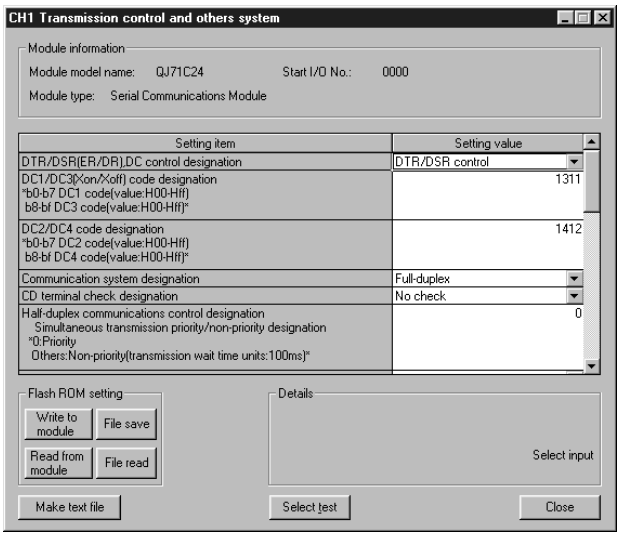
- Online operation

  [Monitor] screen → CH□ Transmission control system setting

- Offline operation

  [Flash ROM setting] screen → CH□ Transmission control system setting

[Setting screen]



[Setting items]

Setting item	Setting value storage buffer memory address	Reference section containing detailed explanation
DTR/DSR (ER/DR), DC control designation	93H/133H	Chapter 7 of User's Manual (Application)
DC1/DC3 (Xon/Xoff) code designation	94H/134H	
DC2/DC4 code designation	95H/135H	
Communication system designation	98H/138H	Section 3.2 of User's Manual (Basic)
CD terminal check designation	97H/137H	
Half-duplex communications control designation Simultaneous transmission priority/non-priority designation	99H/139H	Chapter 8 of User's Manual (Application)
Half-duplex communications control designation Retransmission time transmission method designation	9AH/13AH	
No-reception monitoring time (timer 0) designation	9CH/13CH	Chapter 6 of User's Manual (Application)
Response monitoring time (timer 1) designation	9DH/13DH	
Transmission monitoring time (timer 2) designation	9EH/13EH	
Word/byte units designation	96H/136H	Chapter 5 of User's Manual (Application)
Transmission buffer memory head address designation	A2H/142H	Chapters 6 and 7 of User's Manual (Basic)
Transmission buffer memory length designation	A3H/143H	
Receive buffer memory head address designation	A6H/146H	
Receive buffer memory length designation	A7H/147H	
Transmission transparent code designation 1st	11FH/1BFH	Chapter 12 of User's Manual (Application)
Transmission transparent code designation 2nd to 10th	2030H to 2038H/ 2130H to 2138H	
Receive transparent code designation	120H/1C0H	
ASCII-BIN conversion designation	121H/1C1H	Chapter 13 of User's Manual (Application)
Receive interrupt-issued designation	2010H/2110H	Chapter 4 of User's Manual (Application)

8.4.6 MC protocol system setting

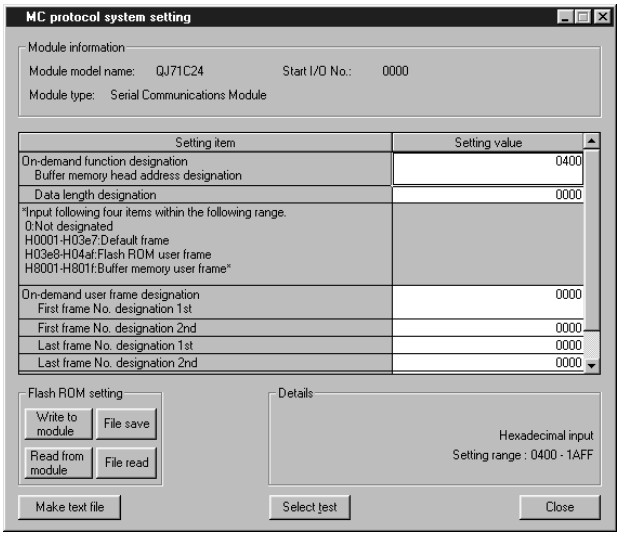
[Purpose]

For data transmission using the MC protocol, register system setting values.

[Startup procedure]

- Online operation
  [Monitor] screen → CH□ MC protocol system setting
- Offline operation
  [Flash ROM setting] screen → CH□ MC protocol system setting

[Setting screen]



[Setting items]

Setting item		Setting value storage buffer memory address	Reference section containing detailed explanation
On-demand function designation	Buffer memory head address designation	A0H/140H	Chapter 10 of User's Manual (Application)
	Data length designation	A1H/141H	
On-demand user frame designation	First frame No. designation 1st	A9H/149H	
	First frame No. designation 2nd	AAH/14AH	
	Last frame No. designation 1st	ABH/14BH	
	Last frame No. designation 2nd	ACH/14CH	
Message wait time designation waiting time ✻ units: 10 ms ✻		11EH/1BEH	

8.4.7 Non procedure system setting

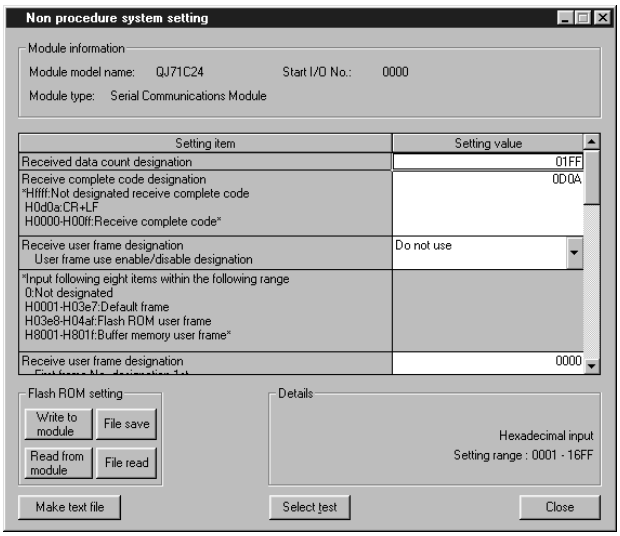
[Purpose]

For data transmission using the non procedure protocol, register system setting values.

[Startup procedure]

- Online operation
  [Monitor] screen → CH□ Non procedure system setting
- Offline operation
  [Flash ROM setting] screen → CH□ Non procedure system setting

[Setting screen]



[Setting items]

Setting item		Setting value storage buffer memory address	Reference section containing detailed explanation
Received data count designation		A4H/144H	Chapter 6 of User's Manual (Basic)
Receive complete code designation		A5H/145H	
Receive user frame designation	User frame use enable/disable designation	ADH/14DH	Chapters 9 and 11 of User's Manual (Application)
	First frame No. designation 1st to 4th	AEH to B1H/14EH to 151H	
	Last frame No. designation 1st to 4th	B2H to B5H/152H to 155H	
User frame receive format designation 1st to 4th		2020H to 2023H/ 2120H to 2123H	
Exclusive format-1 received data count 1st to 4th		2024H to 2027H/ 2124H to 2127H	
Transmission user frame designation	CR/LF output designation	B7H/157H	
	Output head pointer designation	B8H/158H	
	Output count designation	B9H/159H	

8.4.8 Bidirectional system setting

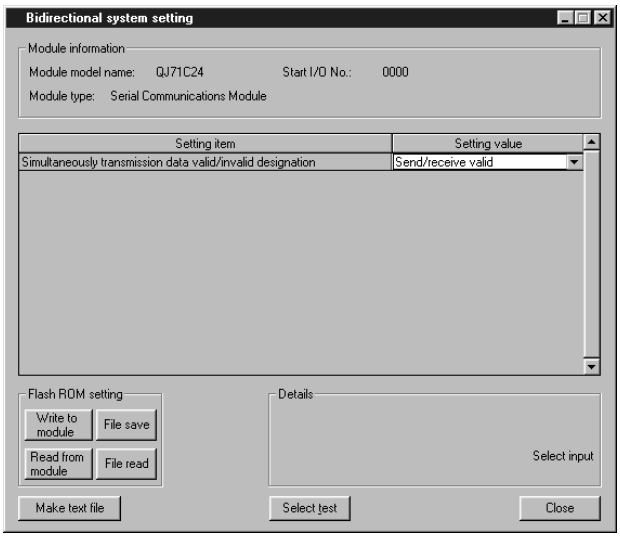
[Purpose]

For data transmission using the bidirectional protocol, register system setting values.

[Startup procedure]

- Online operation
  [Monitor] screen → CH☐ Bidirectional system setting
- Offline operation
  [Flash ROM setting] screen → CH☐ Bidirectional system setting

[Setting screen]



[Setting item]

Setting item	Setting value storage buffer memory address	Reference section containing detailed explanation
Simultaneously transmission data valid/invalid designation	9BH/13BH	Section 7.3 of User's Manual (Basic)

8.4.9 PLC CPU monitoring system setting

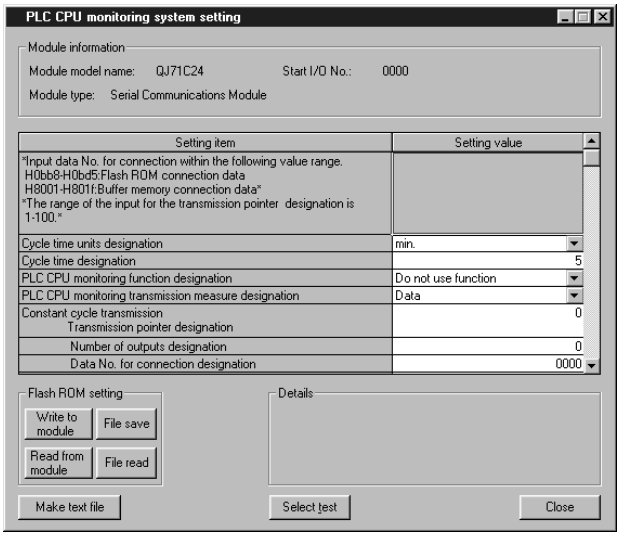
[Purpose]

Register system setting values to use the PLC CPU monitoring function.

[Startup procedure]

- Online operation
  [Monitor] screen → CH□ Monitoring system setting
- Offline operation
  [Flash ROM setting] screen → CH□ Monitoring system setting

[Setting screen]



[Setting items]

Setting item		Setting value storage buffer memory address	Reference section containing detailed explanation
Cycle time units designation		2040H/2140H	Chapter 2 of User's Manual (Application)
Cycle time designation		2041H/2141H	
PLC CPU monitoring function designation		2042H/2142H	
PLC CPU monitoring transmission measure designation		2043H/2143H	
Constant cycle transmission	Transmission pointer	2044H/2144H	
	Output count designation	2045H/2145H	
	Data No. for connection designation	2046H/2146H	
Number of registered word blocks designation		204DH/214DH	
Number of registered bit blocks designation		204EH/214EH	
PLC CPU abnormal monitoring designation		204FH/214FH	
No. n block monitoring device Monitoring device designation		2050H/2150H to 20A1H/21A1H	
Head device No. designation		2051H-2052H/2151H-2152H to 20A1H-20A2H/21A1H-21A2H	
Read point designation		2053H/2153H to 20A3H/21A3H	
Condition agreement transmission Monitoring condition designation		2054H/2154H to 20A4H/21A4H	
Monitoring condition value designation		2055H/2155H to 20A5H/21A5H	
Transmission pointer designation		2056H/2156H to 20A6H/21A6H	
Number of output designation		2057H/2157H to 20A7H/21A7H	
Data No. for connection designation		2058H/2158H to 20A8H/21A8H	
PLC PCU abnormal monitoring designation Condition agreement transmission Transmission pointer		20E5H/21E5H	
Output count designation		20E6H/21E6H	
Data No. for connection designation		20E7H/21E7H	

8.4.10 Transmission user frame No. designation system setting

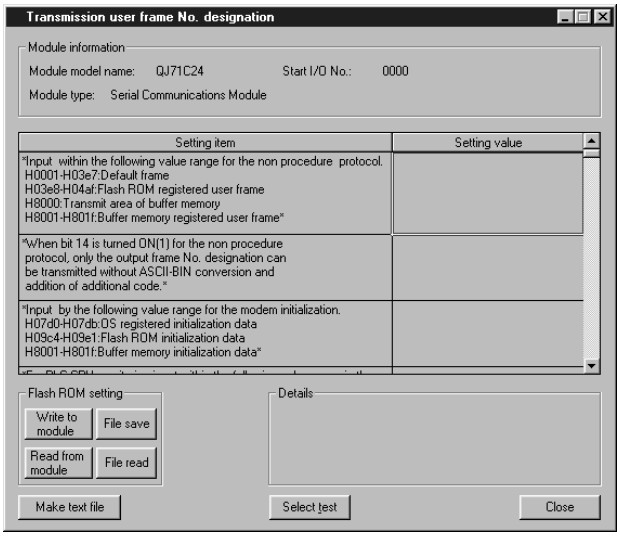
[Purpose]

Register the output frame number to transmit data with the non procedure protocol using the user frame.

[Startup procedure]

- Online operation
  [Monitor] screen → CH□ Output frame system setting
- Offline operation
  [Flash ROM setting] screen → CH□ Output frame system setting

[Setting screen]



[Setting item]

Setting item	Setting value storage buffer memory address	Reference section containing detailed explanation
Output frame No. designation 1st to 100th	BA$_H$ to 11D$_H$/ 15A$_H$ to 1BD$_H$	Chapter 11 of User's Manual (Application)

8.4.11 Resetting the buffer memory/flash ROM setting values to the default values

This section explains how to reset the values set in the buffer memory/flash ROM to their default values.

[Startup procedure]

[Online] → [Monitor/test] →"Select monitor/Test module" → Monitor/test → [Monitor] screen

[Operating procedure]

(Procedure 1) In the [Monitor] screen, select [Default request] for [System setting default].

(Procedure 2) Click on Execute test.

The setting values in the buffer memory will return to their default values.

(Procedure 3) Change the setting of [Flash ROM write allow/prohibit] to "Allowed."

(Procedure 4) In the [Monitor] screen, select [Write request] for [System setting write].

(Procedure 5) Click on Execute test.

The setting values in the flash ROM will return to their default values.

* When confirming the processing results in QSCU, perform Read from module.

(Items subject to this operation in the [Monitor] screen)

Setting item	Current value	Setting value
System setting can be made default with the following procedure. Select test "System setting default" Make "Flash ROM write allow/prohibit designation" "Allow" Select test "System setting write"		
System setting default	Default request	Default request
Flash ROM write allow/prohibit designation	Allow	Allow
System setting write	Write request	Write request

8.4.12 Flash ROM write allow/prohibit setting

This section explains the settings to allow or prohibit writing to the flash ROM.

[Startup procedure]

[Online] → [Monitor/test] → "Select monitor/Test module" → Monitor/test → [Monitor] screen

[Operating procedure]

(Procedure 1) In the [Monitor] screen, select [Flash ROM write allow/prohibit] and set "Allowed" or "Prohibited."

(Procedure 2) Click on Execute test.

[Flash ROM write allow/prohibit] will be set to "Allowed" or "Prohibited," accordingly.

8.5 Auto Refresh Settings

The Auto Refresh Settings are used to automatically store the error information and status information currently stored in the Q series C24's buffer memory in the device specified by the PLC CPU.
For details, see Section 4.6.

8.6 Monitor/Test

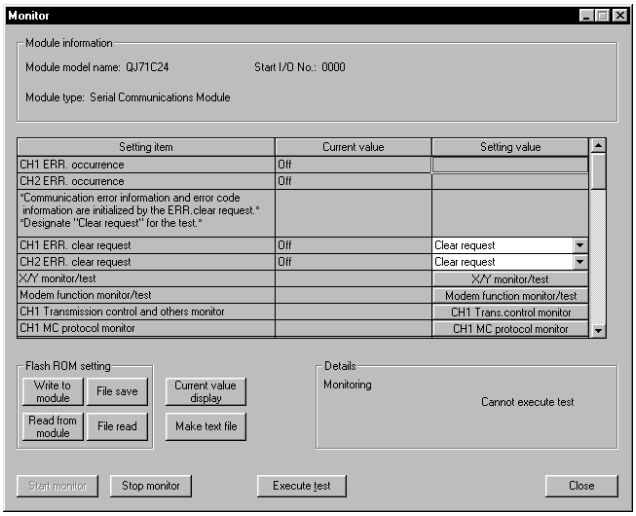
[Purpose]

The displayed menu screen is used to perform various operations, including the monitoring of the Q series C24's operating status and setting values and the testing of its output signals. The monitor/test operations can be performed only via online operation.

[Startup procedure]

* Startup from Intelligent function module utility
  (GX Developer (SW4D5C-GPPW-E or later))
  [Online] → [Monitor/test] → "Select monitor/Test module" → Monitor/test
  → [Monitor] screen
* Startup from the system monitor (GX Developer (SW6D5C-GPPW-E)).
  [GX Developer] → [Diagnostics] → [System Monitor] → "Select the Q series C24 by installation status" → Diagnostics... → [Monitor] screen

[Monitor screen]



[Monitor items]

The following selection menus for monitor/test operation will be displayed.

Function	Reference section containing explanation
ERR. occurrence	Section 8.6.10
ERR. clear request (Communication error information, error code information)	
X · Y monitor/test	Section 8.6.1
Modem function monitor/test	Section 8.6.2
Transmission control and others monitor	Section 8.6.3

8.6.7 PLC CPU monitoring monitor

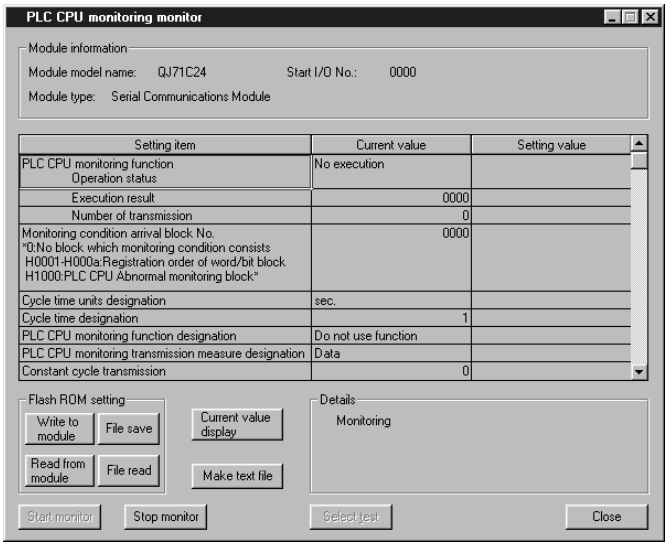
[Purpose]

Monitor the operating status and setting values of the PLC CPU monitoring function.

[Startup procedure]

[Monitor] screen → CH□ Monitoring monitor

[Monitor screen]



[Monitor items]

Monitor items		Setting value storage buffer memory address	Reference section containing detailed explanation
PLC CPU monitoring function	Operation status	2204H/2304H	Chapter 2 of User's Manual (Application)
	Execution result	2205H/2305H	
	Number of transmission	2206H/2306H	
Monitoring condition arrival block No.		2207H/2307H	
Cycle time units designation		2040H/2140H	
Cycle time designation		2041H/2141H	
PLC CPU monitoring function designation		2042H/2142H	
PLC CPU monitoring transmission measure designation		2043H/2143H	
Constant cycle transmission	Transmission pointer	2044H/2144H	
	Output count designation	2045H/2145H	
	Data No. for connection designation	2046H/2146H	
Number of registered word blocks designation		204DH/214DH	
Number of registered bit blocks designation		204EH/214EH	
PLC CPU abnormal monitoring designation		204FH/214FH	
No. n block monitoring device Monitoring device designation		2050H/2150H to 20A1H/21A1H	
Head device No. designation		2051H-2052H/2151H-2152H to 20A1H-20A2H/21A1H-21A2H	
Read point designation		2053H/2153H to 20A3H/21A3H	
Condition agreement transmission Monitoring condition designation		2054H/2154H to 20A4H/21A4H	
Monitoring condition value designation		2055H/2155H to 20A5H/21A5H	
Transmission pointer designation		2056H/2156H to 20A6H/21A6H	
Output count designation		2057H/2157H to 20A7H/21A7H	
Data No. for connection designation		2058H/2158H to 20A8H/21A8H	
PLC PCU abnormal monitoring designation Condition agreement transmission Transmission pointer		20E5H/21E5H	
Number of output designation		20E6H/21E6H	
Data No. for connection designation		20E7H/21E7H	

8.6.8 Transmission user frame No. designation monitor

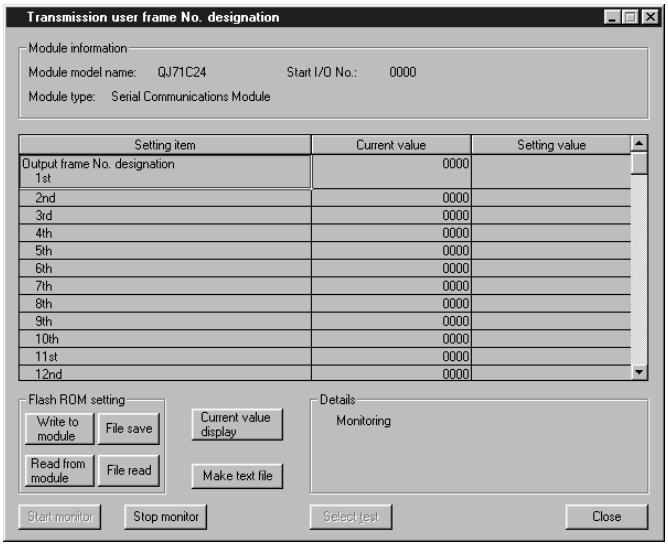
[Purpose]

Monitor the setting value of output frame number used when transmitting data with the non procedure protocol using the user frame.

[Startup procedure]

[Monitor] screen → CH□ Output frame monitor

[Monitor screen]



[Monitor item]

Monitor item	Setting value storage buffer memory address	Reference section containing detailed explanation
Output frame No. designation 1st to 100th	BAH to 11DH/ 15AH to 1BDH	Chapters 9 through 11 of User's Manual (Application)

8.6.9 Monitor others

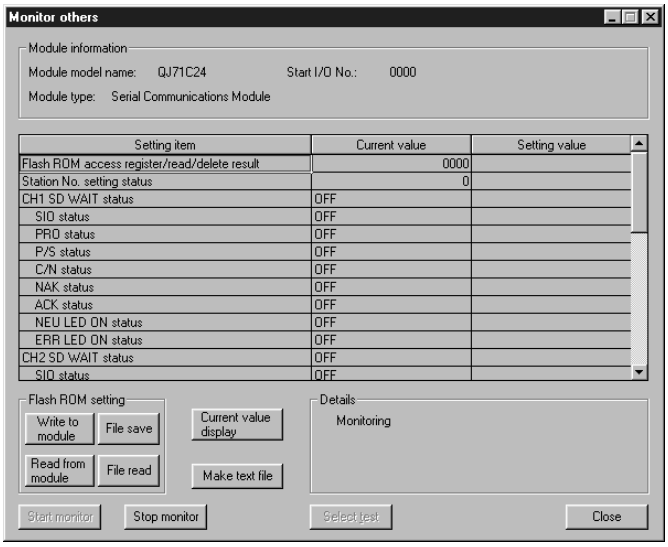
[Purpose]

Monitor the result of access to the flash ROM, the data communication status of each interface, and the result of the intelligent function module switch settings using GX Developer.

[Startup procedure]

[Monitor] screen → Monitor others

[Monitor screen]



[Monitor items]

Monitor items		Setting value storage buffer memory address	Reference section containing detailed explanation
Flash ROM access register/read/delete result		4H	Chapter 10 of User's Manual (Basic)

CH2 Communication protocol setting No. error		203H ··· b4	
CH2 Communication rate setting error		203H ··· b5	
CH2 Mode switching error of setting change prohibit time		203H ··· b7	
Station No. out of range error		203H ··· b14	
Linked operation setting error		203H ··· b15	
Number of registered user frame		204H	
Number of registered default registration frames		21EH	
Flash ROM system parameters write result		220H	

8.6.10 Display LED off and communication error information/error code initialization

This section explains how to turn off the display LEDs of the Q series C24 and initialize its communication error information and error codes.

By using this function, the display LEDs can be turned off and the communication error information and error codes can be initialized, without resetting or powering off the PLC CPU.

[Operation procedure]

(Procedure 1) Display the [Monitor] screen. (See Section 8.4.)
(Procedure 2) Select "Off" in the setting of "All CH error LED off request" or "CHn error LED off request".
(Procedure 3) Click on Execute test.

The communication error information and error codes will be initialized.

8.7 Non Procedure Protocol Receive Data Clear

This section explains how to clear the received data using the non procedure protocol.

By using this function, the receive data can be cleared from QSCU while the communication with the non procedure protocol is still in progress, without resetting the PLC CPU or turning off the power.

[Operation procedure]

(Procedure 1) Display the [Non procedure monitor/test] screen. (See Section 8.6.5.)
(Procedure 2) Set [Clear request issued] for "Receive data clear request".
(Procedure 3) Click on Execute test.

The received data will be cleared.

POINT
Clear the received data when transmission/reception are not in progress with the external device. Executing a receive data clear while the data transmission is in progress causes the Q series C24 to stop the data transmission abruptly, resulting in an abnormal completion of the dedicated transmission instruction. (The transmission completion signal will not be lit.) When the receive data clear is executed while the data reception is in progress, the data received up to that point will be cleared.

9 DEDICATED INSTRUCTIONS

Dedicated instructions are used to simplify programming when using intelligent function module functions.
This chapter describes the dedicated instructions for the Q series C24, which is part of the functions of the QCPU (in Q mode) explained in this manual.

9.1 Dedicated Instruction List

The following table lists the dedicated instructions explained in this chapter.

Application	Dedicated instruction	Description of function	Explanation page
On-demand function transmission	ONDEMAND	Sends data using the on-demand function of the MC protocol.	Section 9.2
Non procedure protocol communication	OUTPUT	Sends data for the specified data count.	Section 9.3
	INPUT	Reads received data.	Section 9.4
Bidirectional protocol communication	BIDOUT	Sends data for the designated data count.	Section 9.5
	BIDIN	Reads received data.	Section 9.6
Communication status confirmation	SPBUSY	Reads the status of data transmission/reception via a dedicated instruction.	Section 9.7
Receive data clear	CSET	Perform the receive data clear without stopping the transmission processing during the non procedure protocol.	Section 9.8

POINT

(1) The user should not change data values (control data, request data, etc.) designated by a dedicated instruction until the execution of the dedicated instruction is completed.

(2) Dedicated instructions for the Q series C24 are executed based on the current setting values stored in the buffer memory.
When it is necessary to change a setting value, change the value by QSCU before starting up the module.
Alternatively, a setting value can be changed via the sequence program using a CSET instruction before starting up the PLC CPU (See the User's Manual (Application)).

1) Area of buffer memory assigned as applicable functions for dedicated instructions.
2) Setting values for data communication
   - Word/byte units designation
   - Receive complete code
   - Received data count

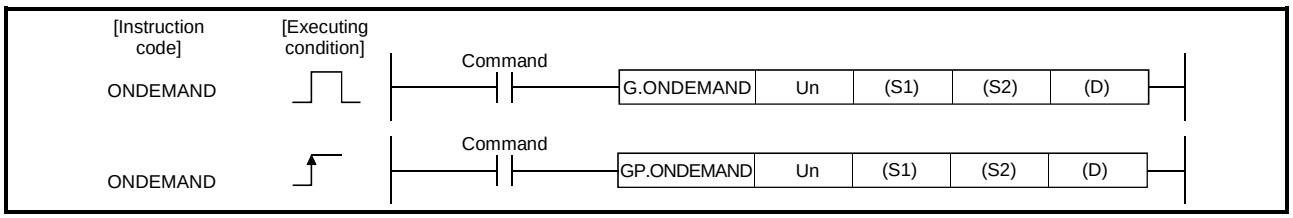
   etc.

9 - 1

9.2 ONDEMAND Instruction

The ONDEAMAND instruction transmission data using the on-demand function of the MC protocol.

Set data	Applicable device								
	Internal device (System, user)		File register	MELSECNET/H, MELSECNET/10 Direct J□\□		Special module U□\G□	Index register Zn	Constant	Others
	Bit	Word		Bit	Word				
(S1)	—	○		—					
(S2)	—	○		—					
(D)	○	○		—					



Set data

Set data	Description	Set by	Data type
Un	Start I/O signal of the module (00 to FE: Top two-digit when I/O signals are expressed in 3-digit.)	User	BIN16 bit
(S1)	Head number of the devices in which control data is stored.	User, system	Device name
(S2)	Head number of the devices in which transmission data is stored.	User	
(D)	Bit device number to be turned on at completion of execution.	System	Bit

The file register per local device and program cannot be used as the set data.

Control data

Device	Item	Set data	Setting range	Set by
(S1) + 0	Transmission channel	• Set transmission channel 1: Channel 1 (CH1 side) 2: Channel 2 (CH2 side)	1, 2	User
(S1) + 1	Transmission result	• Result read by an ONDEMAND instruction is stored. 0: Normal Other than 0: Error code ＊1	—	System
(S1) + 2	Transmission data count	• Set the transmission data count.＊2	1 or more	User

＊1 For error codes relating to abnormal completion, see Chapter 10 of the User's Manual (Basic).

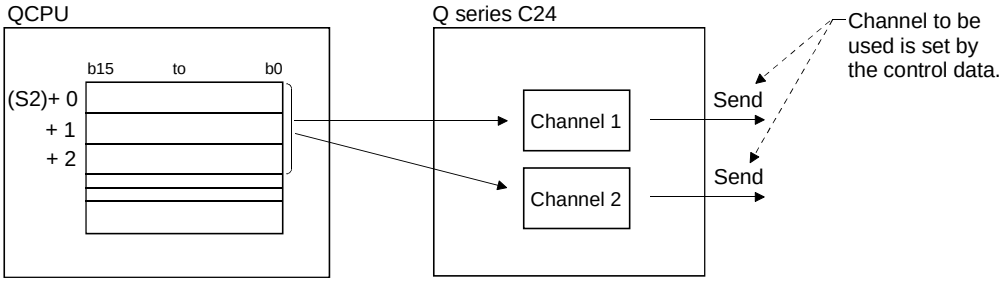
＊2 When setting "Word/byte units designation" by QSCU, set the number of bytes when bytes are designated and set the number of words when words are designated.

＊3 The settings are done by either of the following:

- User: Data set by the user before executing the ONDEMAND instructions.
- System: The PLC CPU stores the execution result of the ONDEMAND instructions.

Function

(1) Data stored in the device designated in (S2) and succeeding devices are sent according to the control data of the device designated in (S1) and succeeding devices, via the on-demand function of the MC protocol of the module designated in Un.



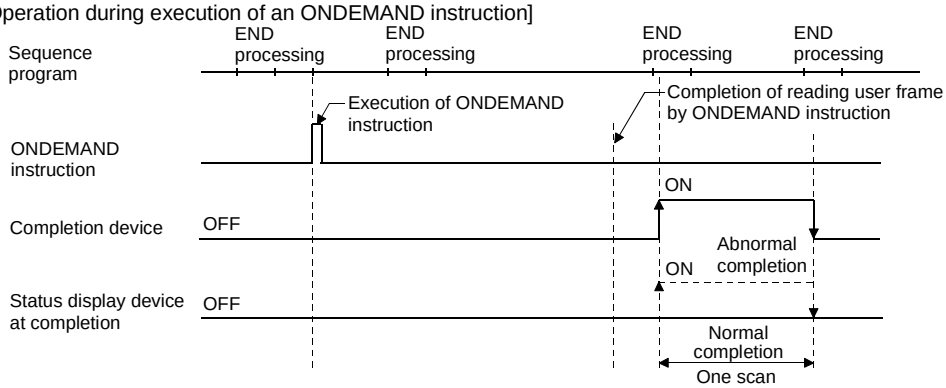
(2) When an ONDEMAND instruction is executed on a channel, other ONDEMAND instructions cannot be executed on that channel at the same time.
If an attempt is made during execution of an ONDEMAND instruction to execute another ONDEMAND instruction, the second instruction will not be executed until the execution of the first instruction is completed.

(3) Whether an ONDEMAND instruction was completed normally or abnormally can be checked by the completion device ((D)) or status display device at completion ((D)+1).

(a) Completion device : Turns on at the END processing of the scan where the ONDEMAND instruction is completed, and turns off at the next END processing.

(b) Status display device at completion : Turns on and off depending on the completion status of the ONDEMAND instruction.
- Normal completion : Off with no change.
- Abnormal completion: Turns on at the END processing of the scan where the ONDEMAND instruction is completed, and turns off at the next END processing.

[Operation during execution of an ONDEMAND instruction]

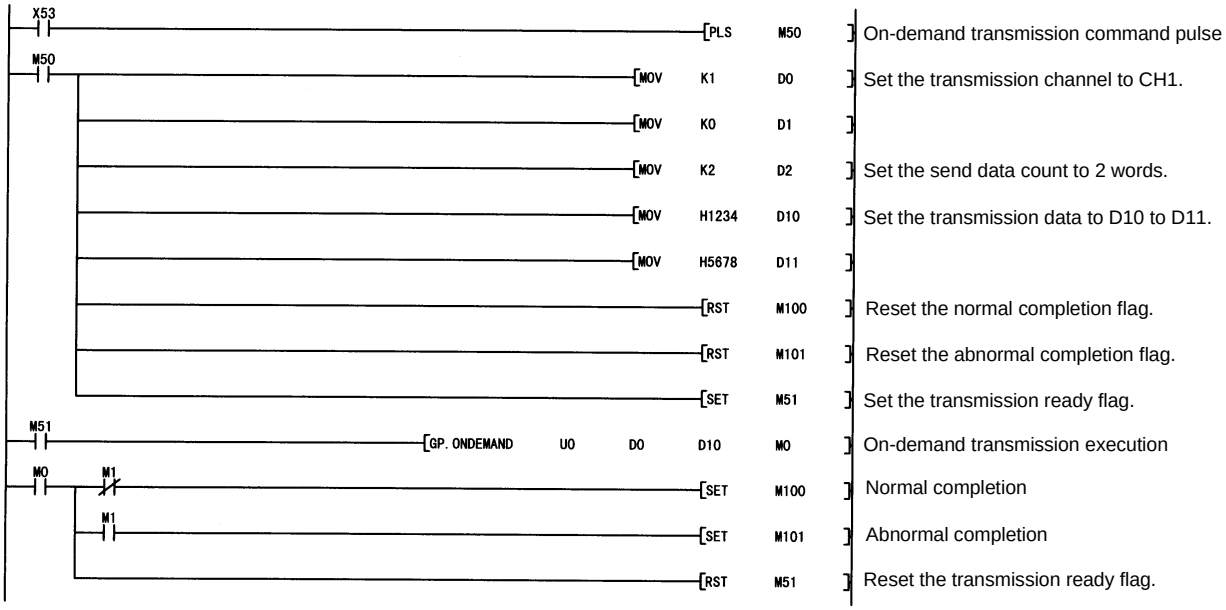


Error

(1) When a dedicated instruction is completed abnormally, the abnormal completion signal, (D)+1, turns on and the error code is stored in the transmission result (S1)+1.
In case of operation errors, the error flag (SM0) turns on and the error code is stored in the SD0.
See one of the following manuals according to the error code, and check and correct the error.
<Error code>
4FFF$_H$ or less : QCPU(Q Mode) User's Manual
(Hardware Design, Maintenance and Inspection)
7000$_H$ or more: Section 10.2 of the User's Manual (Basic)

Program example

A program that sends data stored in D10 to D11 using an on-demand transmission
When input/output signals of the Q series C24 are from X/Y00 to X/Y1F



POINT

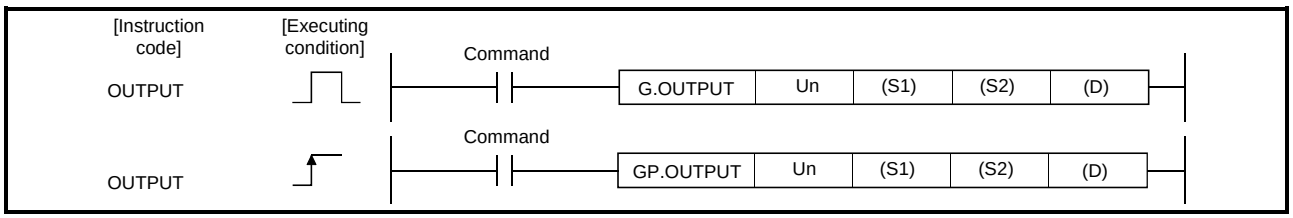
(1) The status of communication via dedicated instructions can be read by an SPBUSY instruction.

(2) Designate the storage capacity of transmission data (stored in D10 to D11 in the program example above) and data length (stored in D2 in the program example above) within the range of the buffer memory the user has assigned for an on-demand function.

9.3 OUTPUT Instruction

This instruction transmission data in any message format specified by the user using the non procedure protocol.

Set data	Applicable device								
	Internal device (System, user)		File register	MELSECNET/H, MELSECNET/10 Direct J□\□		Special module U□\G□	Index register Zn	Constant	Others
	Bit	Word		Bit	Word				
(S1)	—	○		—					
(S2)	—	○		—					
(D)	○	○		—					



Set data

Set data	Description	Set by	Data type
Un	Start I/O signal of the module (00 to FE: Top two-digit when I/O signals are expressed in 3-digit.)	User	BIN16 bit
(S1)	Head number of the devices in which control data is stored.	User, system	Device name
(S2)	Head number of the devices in which transmission data is stored.	User	
(D)	Bit device number to be turned on at completion of execution.	System	Bit

The file register per local device and program cannot be used as the set data.

Control data

Device	Item	Set data	Setting range	Set by
(S1) + 0	Transmission channel	• Set transmission channel 1: Channel 1 (CH1 side) 2: Channel 2 (CH2 side)	1, 2	User
(S1) + 1	Transmission result	• Transmission result by an OUTPUT instruction are stored. 0: Normal Other than 0: Error code ＊1	—	System
(S1) + 2	Transmission data count	• Set the transmission data count.＊2	1 or more	User

＊1 For error codes relating to abnormal completion, see Chapter 10 of the User's Manual (Basic).

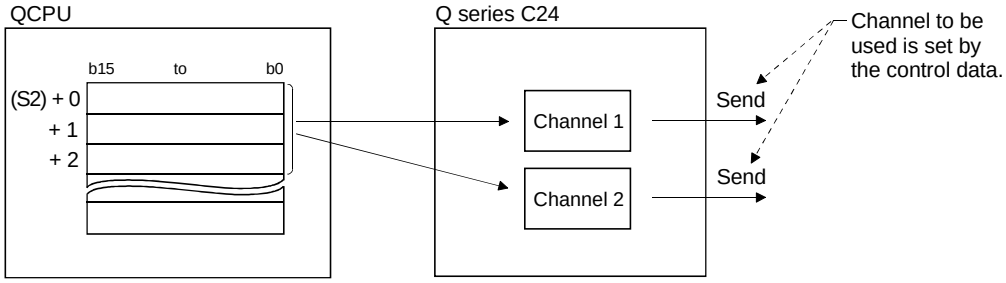
＊2 When setting "Word/byte units designation" by QSCU, set the number of bytes when bytes are designated and set the number of words when words are designated and set the number of words when words are selected as the unit types.

＊3 The settings are done by either of the following:

- User: Data set by the user before executing the OUTPUT instructions.
- System: The PLC CPU stores the execution result of the OUTPUT instructions.

Function

(1) Data stored in the device designated in (S2) and succeeding devices are sent according to the control data of the device designated in (S1) and succeeding devices, via the non procedure protocol of the module specified in Un.



(2) The following instructions cannot be executed on a channel on which an OUTPUT instruction is being executed.

- Other OUTPUT instructions
- PRR instructions

If an attempt is made during execution of an OUTPUT instruction to execute one of the instructions above, the second instruction will not be executed until the execution of the OUTPUT instruction is completed.

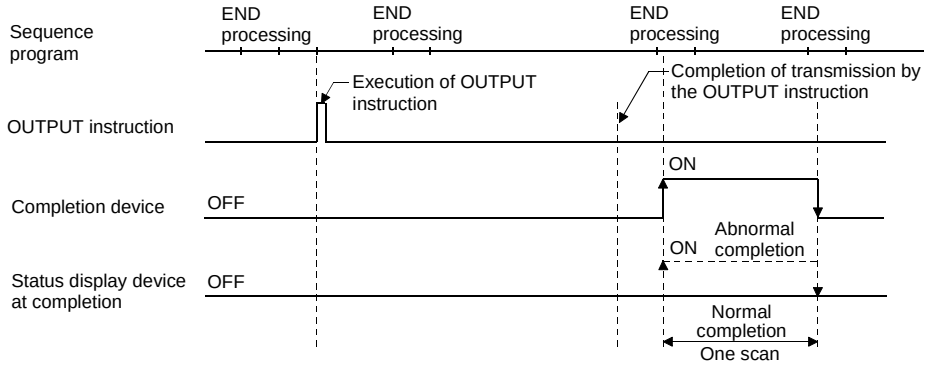
(3) Whether an OUTPUT instruction was completed normally or abnormally can be checked by the completion device ((D)) or status display device at completion ((D)+1).

(a) Completion device: Turns on at the END processing of the scan where the OUTPUT instruction is completed, and turns off at the next END processing.

(b) Status display device at completion : Turns on and off depending on the completion status of the OUTPUT instruction.

- Normal completion : Off with no change.
- Abnormal completion: Turns on at the END processing of the scan where the OUTPUT instruction is completed, and turns off at the next END processing.

[Operation during execution of an OUTPUT instruction]

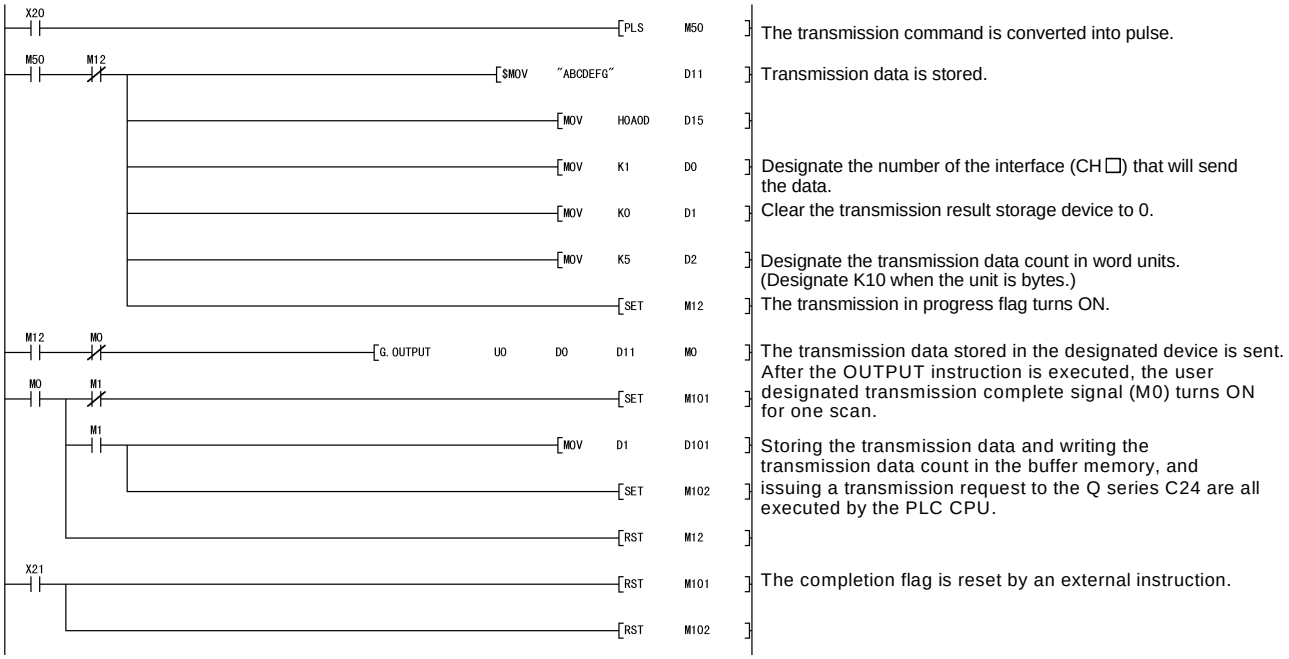


Error

(1) When a dedicated instruction is completed abnormally, the abnormal completion signal, (D)+1, turns on and the error code is stored in the transmission result (S1)+1.
In case of operation errors, the error flag (SM0) turns on and the error code is stored in the SD0.
See one of the following manuals according to the error code, and check and correct the error.
<Error code>
4FFF$_H$ or less : QCPU(Q Mode) User's Manual
(Hardware Design, Maintenance and Inspection)
7000$_H$ or more: Section 10.2 of the User's Manual (Basic)

Program example

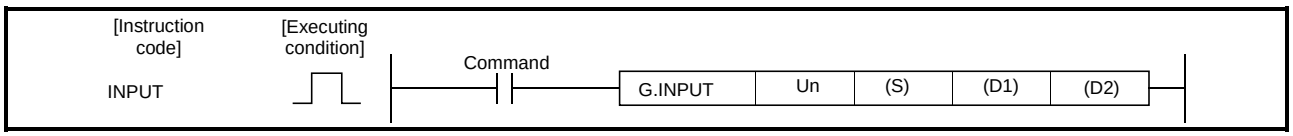
The following example shows a program that sends any data stored in D11 to D15 using the non procedure protocol.
When input/output signals of the Q series C24 are from X/Y00 to X/Y1F:



9.4 INPUT Instruction

This instruction receives data in any message format specified by the user using the non procedure protocol.

Set data	Applicable device								
	Internal device (System, user)		File register	MELSECNET/H, MELSECNET/10 Direct J□\□		Special module U□\G□	Index register Zn	Constant	Others
	Bit	Word		Bit	Word				
(S)	—	○		—					
(D1)	—	○		—					
(D2)	○	○		—					



Set data

Set data	Description	Set by	Data type
Un	Start I/O signal of the module (00 to FE: Top two-digit when I/O signals are expressed in 3-digit.)	User	BIN16 bit
(S)	Head number of the devices in which control data is stored.	User, system	Device name
(D1)	Head number of the devices in which receive data is stored.	System	
(D2)	Bit device number to be turned on at completion of execution.	System	Bit

The file register per local device and program cannot be used as the set data.

Control data

Device	Item	Set data	Setting range	Set by
(S) + 0	Receive channel	• Set receive channel 1: Channel 1 (CH1 side) 2: Channel 2 (CH2 side)	1, 2	User
(S) + 1	Reception result	• Reception result by an INPUT instruction are stored. 0: Normal Other than 0: Error code ＊1	—	System
(S) + 2	Receive data count	• Receive data count is stored. ＊2	0 or more	System
(S) + 3	Allowable number of receive data	• Set the allowable number of words for received data that can be stored in (D1).	1 or more	User

POINT

(1) The command of G.INPUT cannot be converted into pulse.

(2) G.INPUT should be executed while the read request of the input/output signal is turned on.

*1 For error codes relating to abnormal completion, see Chapter 10 of the User's Manual (Basic).

*2 When setting "Word/byte units designation" by QSCU, set the number of bytes when bytes are designated and set the number of words when words are designated.

*3 The settings are done by either of the following:
- User: Data set by the user before executing the INPUT instructions.
- System: The PLC CPU stores the execution result of the INPUT instructions.

Function

(1) The function stores in the device designated in (D1) and succeeding devices the data received with the non procedure protocol of the module designated in Un, according to the control data of the device designated in (S) and succeeding devices.

(2) When an INPUT instruction is executed on a channel, other INPUT instructions cannot be executed on the channel at the same time.
If an attempt is made during execution of an INPUT instruction to execute another INPUT instruction, the second instruction will not be executed until the execution of the first INPUT instruction is completed.

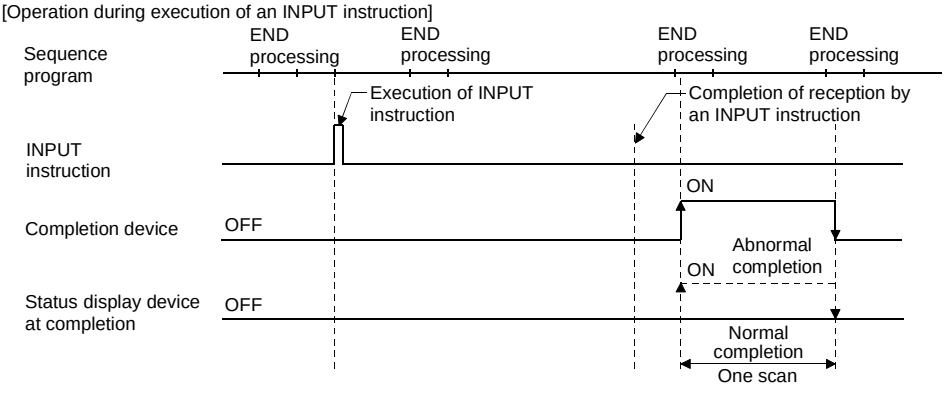
(3) In case of reading the receive data to the same interface, it cannot be used along with BUFRCVS instruction (for interrupt programs).

(4) Whether an INPUT instruction was completed normally or abnormally can be checked by the completion device ((D2)) or status display device at completion ((D2)+1).

(a) Completion device: Turns on at the END processing of the scan where the INPUT instruction is completed, and turns off at the next END processing.

(b) Status display device at completion : Turns on and off depending on the completion status of the INPUT instruction.
- Normal completion : Off with no change.
- Abnormal completion: Turns on at the END processing of the scan where the INPUT instruction is completed, and turns off at the next END processing.

[Operation during execution of an INPUT instruction]

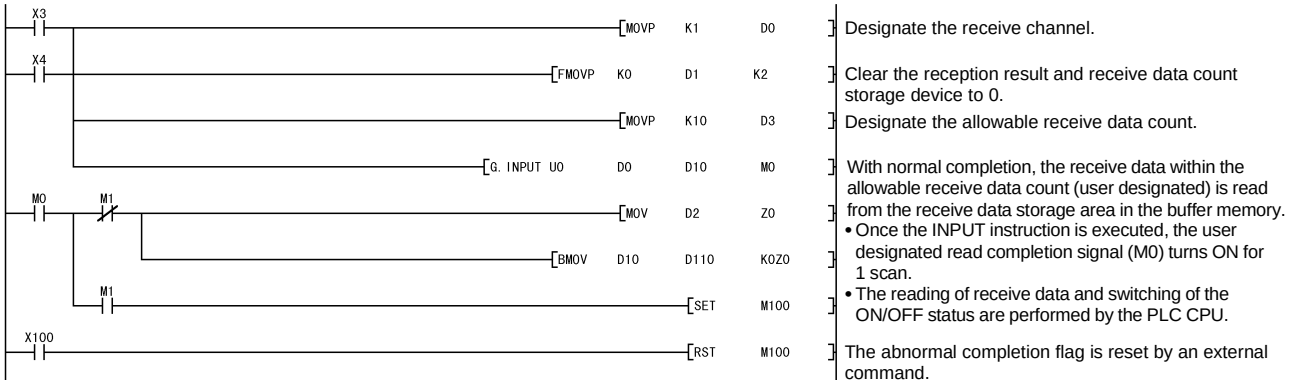


Error

(1) When a dedicated instruction is completed abnormally, the abnormal completion signal (D2)+1, turns on and the error code is stored in the transmission result (S1)+1.
In case of operation errors, the error flag (SM0) turns on and the error code is stored in SD0.
See one of the following manuals according to the error code, and check and correct the error.
<Error code>
4FFF$_H$ or less : QCPU(Q Mode) User's Manual
(Hardware Design, Maintenance and Inspection)
7000$_H$ or more: Section 10.2 of the User's Manual (Basic)

Program example

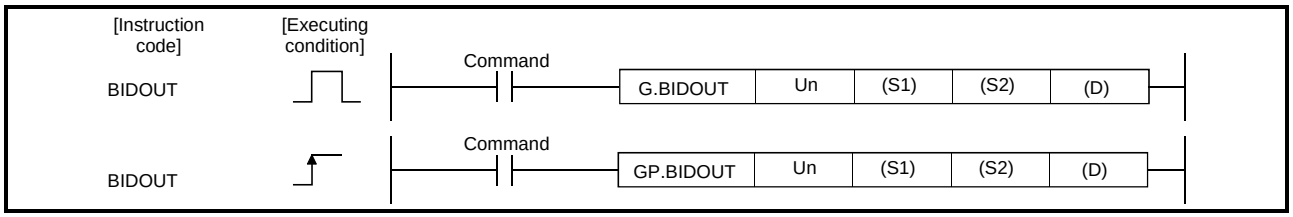
The following example shows a program that stores data received via the non-procedure protocol in D10 and later.
When the input/output signals of the Q series C24 are from X/Y00 to X/Y1F:



9.5 BIDOUT Instruction

This instruction transmission data using the bidirectional protocol.

Set data	Applicable device								
	Internal device (System, user)		File register	MELSECNET/H, MELSECNET/10 Direct J□\□		Special module U□\G□	Index register Zn	Constant	Others
	Bit	Word		Bit	Word				
(S1)	—	○		—					
(S2)	—	○		—					
(D)	○	○		—					



Set data

Set data	Description	Set by	Data type
Un	Start I/O signal of the module (00 to FE: Top two-digit when I/O signals are expressed in 3-digit.)	User	BIN16 bit
(S1)	Head number of the devices in which control data is stored.	User, system	Device name
(S2)	Head number of the devices in which transmission data is stored.	User	
(D)	Bit device number to be turned on at completion of execution.	System	Bit

The file register per local device and program cannot be used as the set data.

Control data

Device	Item	Set data	Setting range	Set by
(S1) + 0	Transmission channel	• Set transmission channel 1: Channel 1 (CH1 side) 2: Channel 2 (CH2 side)	1, 2	User
(S1) + 1	Transmission result	• Transmission result by a BIDOUT instruction are stored. 0: Normal Other than 0: Error code ＊1	—	System
(S1) + 2	Transmission data count	• Set the transmission data count.＊2	1 or more	User

＊1 For error codes relating to abnormal completion, see Chapter 10 of the User's Manual (Basic).

＊2 When setting "Word/byte units designation" by QSCU, set the number of bytes when bytes are designated and set the number of words when words are designated.

＊3 The settings are done by either of the following:

- User: Data set by the user before executing the BIDOUT instructions.
- System: The PLC CPU stores the execution result of the BIDOUT instructions.

Function

(1) The function sends data stored in the device designated in (S2) and succeeding devices according to the control data of the device designated in (S1) and succeeding devices, via the bidirectional protocol of the module designated in Un.

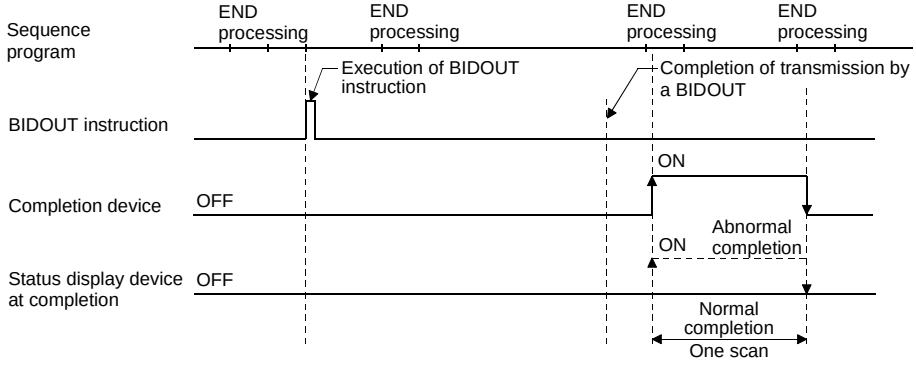
(2) When a BIDOUT instruction is executed on a channel, other BIDOUT instructions cannot be executed on that channel at the same time.
If an attempt is made during execution of a BIDOUT instruction to execute another BIDOUT instruction, the second instruction will not be executed until the execution of the first instruction is completed.

(3) Whether a BIDOUT instruction was completed normally or abnormally can be checked by the completion device ((D)) or status display device at completion ((D)+1).

(a) Completion device: Turns on at the END processing of the scan where the BIDOUT instruction is completed, and turns off at the next END processing.

(b) Status display device at completion : Turns on and off depending on the completion status of the BIDOUT instruction.
- Normal completion : Off with no change.
- Abnormal completion: Turns on at the END processing of the scan where the BIDOUT instruction is completed, and turns off at the next END processing.

[Operation during execution of a BIDOUT instruction]



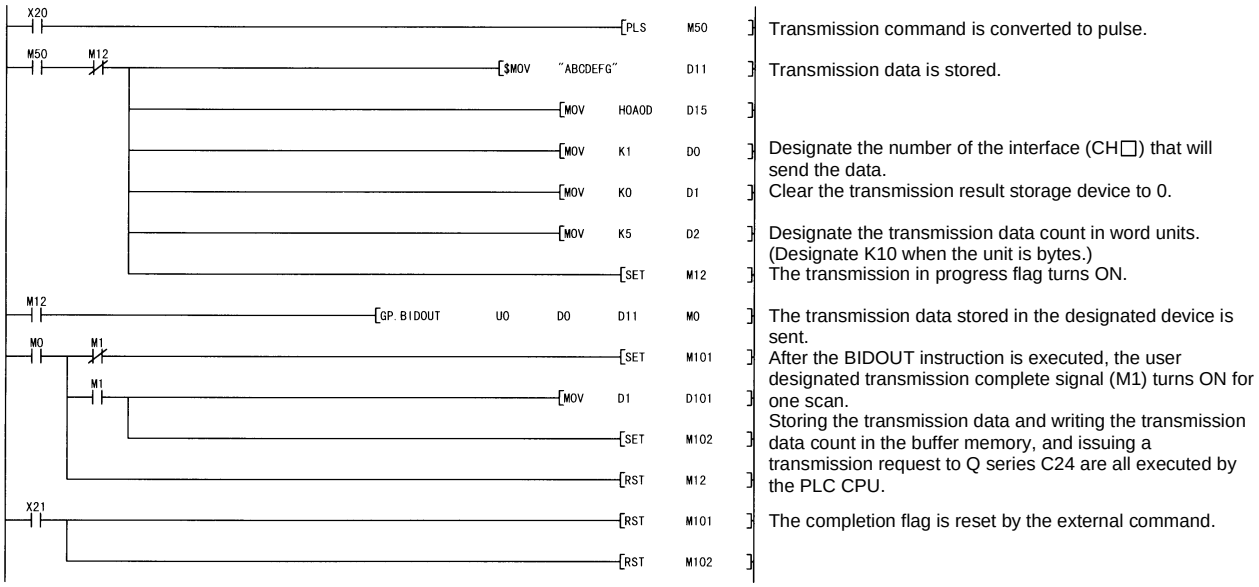
Error

(1) When a dedicated instruction is completed abnormally, the abnormal completion signal (D)+1, turns on and the error code is stored in the transmission result (S1)+1.
In case of operation errors, the error flag (SM0) turns on and the error code is stored in SD0.
See one of the following manuals according to the error code, and check and correct the error.
<Error code>
4FFF$_H$ or less : QCPU(Q Mode) User's Manual
(Hardware Design, Maintenance and Inspection)
7000$_H$ or more: Section 10.2 of the User's Manual (Basic)

Program example

The following example shows a program that sends any data stored in D11 to D15 using the bidirectional protocol.

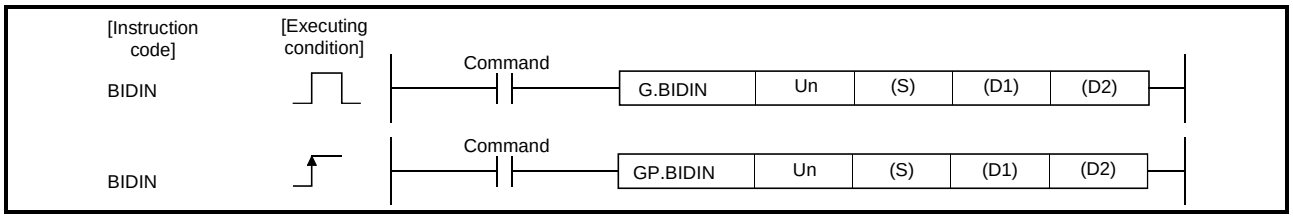
When the input/output signals of the Q series C24 are from X/Y00 to X/Y1F:



9.6 BIDIN Instruction

This instruction receives data using the bidirectional protocol.

Set data	Applicable device								
	Internal device (System, user)		File register	MELSECNET/H, MELSECNET/10 Direct J□\□		Special module U□\G□	Index register Zn	Constant	Others
	Bit	Word		Bit	Word				
(S)	—	○		—					
(D1)	—	○		—					
(D2)	○	○		—					



Set data

Set data	Description	Set by	Data type
Un	Start I/O signal of the module (00 to FE: Top two-digit when I/O signals are expressed in 3-digit.)	User	BIN16 bit
(S)	Head number of the devices in which control data is stored.	User, system	Device name
(D1)	Head number of the devices in which receive data is stored.	System	
(D2)	Bit device number to be turned on at completion of execution.	System	Bit

The file register per local device and program cannot be used as the set data.

Control data

Device	Item	Set data	Setting range	Set by
(S) + 0	Receive channel	• Set receive channel 1: Channel 1 (CH1 side) 2: Channel 2 (CH2 side)	1, 2	User
(S) + 1	Reception result	• Reception result by a BIDIN instruction are stored. 0: Normal Other than 0: Error code ＊1	—	System
(S) + 2	Receive data count	• The number of data received is stored.＊2	1 or more	System
(S) + 3	Allowable number of receive data	• Set the allowable number of words for received data that can be stored in (D1).	1 or more	User

POINT

(1) The command of G (P).BIDIN cannot be converted into pulse.

(2) G (P).BIDIN should be executed while the read request of the input/output signal is turned on.

*1 For error codes relating to abnormal completion, see Chapter 10 of the User's Manual (Basic).

*2 When setting "Word/byte units designation" by QSCU, set the number of bytes when bytes are designated and set the number of words when words are designated as the unit types.

*3 The settings are done by either of the following:
- User: Data set by the user before executing the BIDIN instructions.
- System: The PLC CPU stores the execution result of the BIDIN instructions.

Function

(1) The function stores in the device designated in (D1) and succeeding devices the data received via the bidirectional protocol of the module designated in Un, according to the control data of the device designated in (S) and succeeding devices.

(2) When a BIDIN instruction is executed on a channel, other BIDIN instructions cannot be executed on the channel at the same time.
If an attempt is made during execution of a BIDIN instruction to execute another BIDIN instruction, the second instruction will not be executed until the execution of the first instruction is completed.

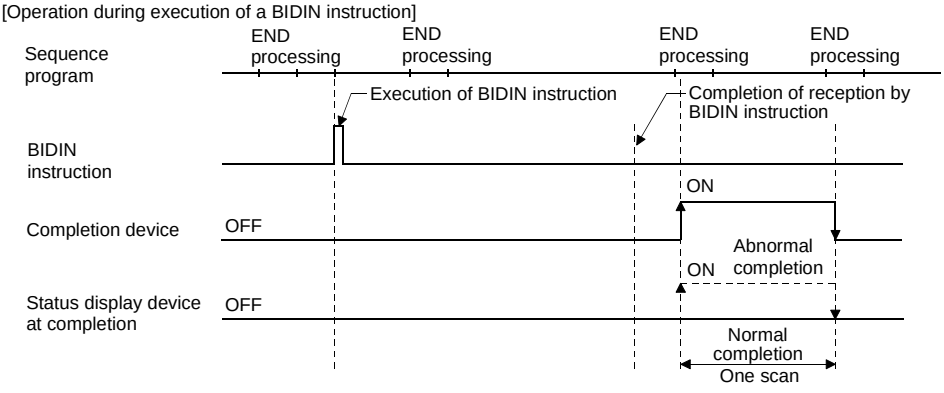
(3) It cannot be used along with BUFRCVS instruction (for interrupt programs).

(4) Whether a BIDIN instruction was completed normally or abnormally can be checked by the completion device ((D2)) or status display device at completion ((D2)+1).

(a) Completion device: Turns on at the END processing of the scan where the BIDIN instruction is completed, and turns off at the next END processing.

(b) Status display device at completion : Turns on and off depending on the completion status of the BIDIN instruction.
- Normal completion : Off with no change.
- Abnormal completion: Turns on at the END processing of the scan where the BIDIN instruction is completed, and turns off at the next END processing.

[Operation during execution of a BIDIN instruction]



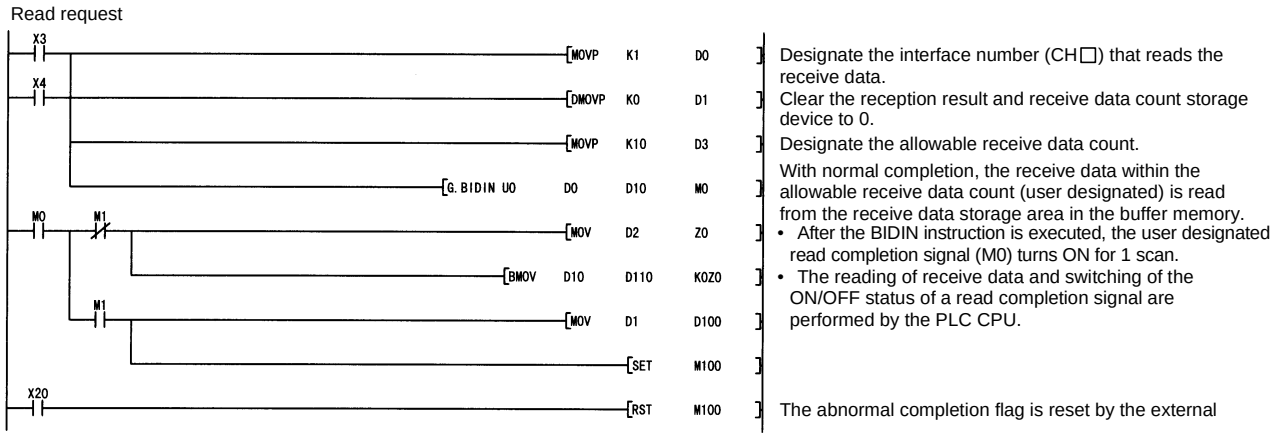
Error

(1) When a dedicated instruction is completed abnormally, the abnormal completion signal (D2)+1, turns on and the error code is stored in the transmission result (S1)+1.
In case of operation errors, the error flag (SM0) turns on and the error code is stored in SD0.
See one of the following manuals according to the error code, and check and correct the error.
<Error code>
4FFF$_H$ or less : QCPU(Q Mode) User's Manual
(Hardware Design, Maintenance and Inspection)
7000$_H$ or more: Section 10.2 of the User's Manual (Basic)

Program example

The following example shows a program that receives any data using the bidirectional protocol and stores that data in D10 or later.

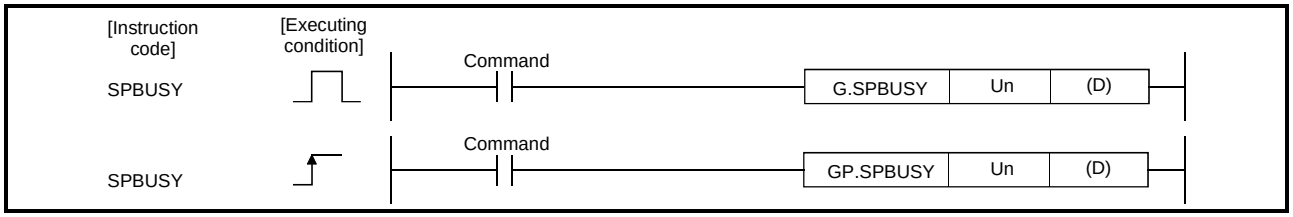
The input/output signals of the Q series C24 are from X/Y00 to X/Y1F:



9.7 SPBUSY Instruction

This instruction reads the status of data transmission and reception executed with dedicated instructions.

Set data	Applicable device								
	Internal device (System, user)		File register	MELSECNET/H, MELSECNET/10 Direct J□\□		Special module U□\G□	Index register Zn	Constant	Others
	Bit	Word		Bit	Word				
(D)	○			—					



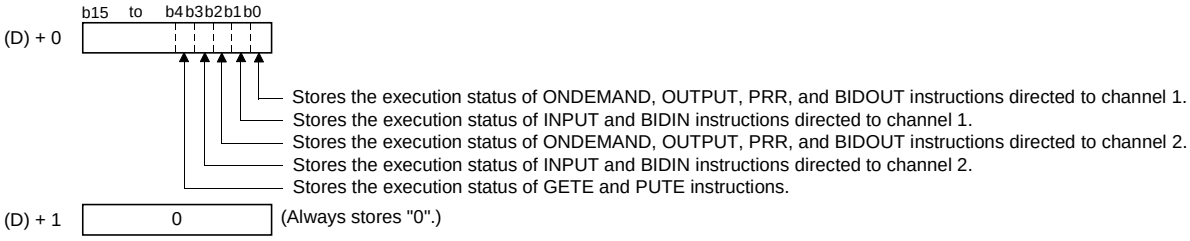
Set data

Set data	Description	Set by	Data type
Un	Start I/O signal of the module (00 to FE: Top two-digit when I/O signals are expressed in 3-digit.)	User	BIN16 bit
(D)	Head number of devices in which the read communication status is stored.	System	Device name

Function

(1) The function reads the execution status of a dedicated instruction directed to a module designated by the start I/O signal, and stores it in the device designated by (D) or later.

(2) The execution status is stored in (D) in the form of "1" at the corresponding bit when the processing of each instruction is started, and "0" when the processing is completed.
The processing of each instruction is completed when the completion flag of each instruction is turned from on to off.



(3) The SPBUSY instruction is executed for every scan while the read command is ON, if the system is executing during ON. And, the instruction will be executed for a single scan when the read command rises from OFF to ON, if the system is starting up.

Error

(1) In case of operation errors, the error flag (SM0) turns on and the error code is stored in SD0.
See one of the following manuals according to the error code, and check and correct the error.
<Error code>
4FFF$_H$ or less : QCPU(Q Mode) User's Manual
(Hardware Design, Maintenance and Inspection)
7000$_H$ or more: Section 10.2 of the User's Manual (Basic)

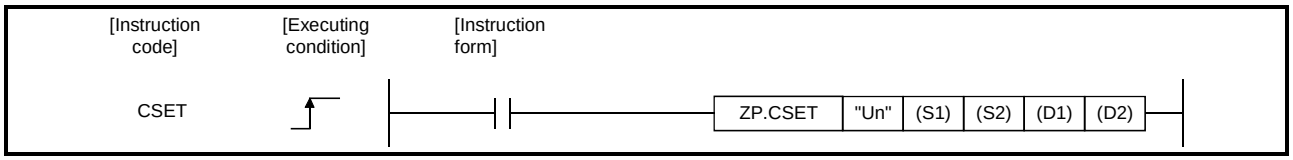
Program example

A program that reads the communication status of a target module.

When input/output signals of the Q series C24 are from X/Y00 to X/Y1F

9.8 CSET (Receive data clear)

Set data	Applicable device								
	Internal device (System, user)		File register	MELSECNET/H, MELSECNET/10 Direct J□\□		Special module U□\G□	Index register Zn	Constant	Others
	Bit	Word		Bit	Word				
(S1)	—	○		—				K, H	—
(S2)	—	○		—					
(D1)	—	○		—					
(D2)	○	○		—					



Set data

Set data	Description	Set by	Data type
"Un"	Start I/O signal of the module (00 to FE: Top two-digit when I/O signals are expressed in 3-digit.)	User	BIN16 bit
(S1)	Number of the channel that transmits the monitoring result. 1: Channel 1 (CH1 side) 2: Channel 2 (CH2 side)		
(S2)	Head number of the device that stores the control data.	User, System	Device name
(D1)	Dummy	—	Device name
(D2)	Head number of the bit device at the self-station that turns on for one scan at the completion of the instruction. (D2) + 1 also turns on at an abnormal completion.	System	Bit

Each of file registers for local device and program cannot be used as the setting data.

Control data

Device	Item	Set data	Setting range	Set by
(S2) + 0	Execution type	Select 0.	0	User
(S2) + 1	Complete status	The execution result at the completion of the instruction is stored. 0: Normal Other than 0: Abnormal (error code)	—	System
(S2) + 2	Request type	Specify the request. 4: Receive data clear request	4	User

REMARK

(1) See the "Error" explanation on the following page for details on errors caused by wrong data specifications by the user.

(2) The setting sides are partitioned as follows:
- User: Data set by the user before executing the dedicated instruction.
- System: The PLC CPU stores the execution result of the dedicated instruction.

Function

(1) This function clears reception data in the OS area. It does not clear the user data reception area in the buffer memory.

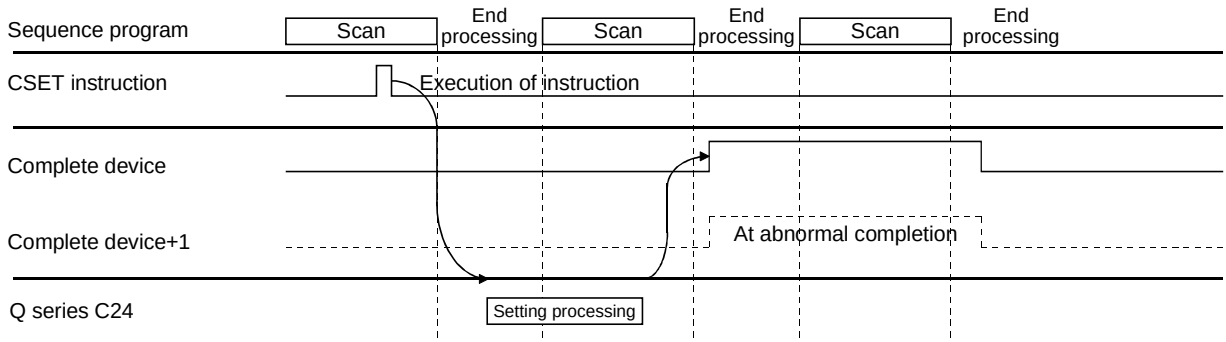
(2) If the CSET instruction is executed while the read request (X03/X0A) or reception abnormal detection signal (X04/X0B) is turned on, the CSET instruction is kept waiting until the signal is turned off.

(3) The status of the CSET instruction, whether it is being executed or completed normally/abnormally, can be checked by the complete device (D2) specified by the setting data.

(a) Complete device ((D2) + 0)
This device turns on at the End processing of the scan at which the CSET instruction is completed and turns off at the next End processing.

(b) Complete device ((D2) + 1)
It turns on/off by the status at which the CSET instruction is completed.
- At normal completion: It is kept turned off and does not change.
- At abnormal completion: It turns on at the END processing of the scan at which the CSET instruction is completed and turns off at the next END processing.

[Operation at execution of CSET instruction]



Error

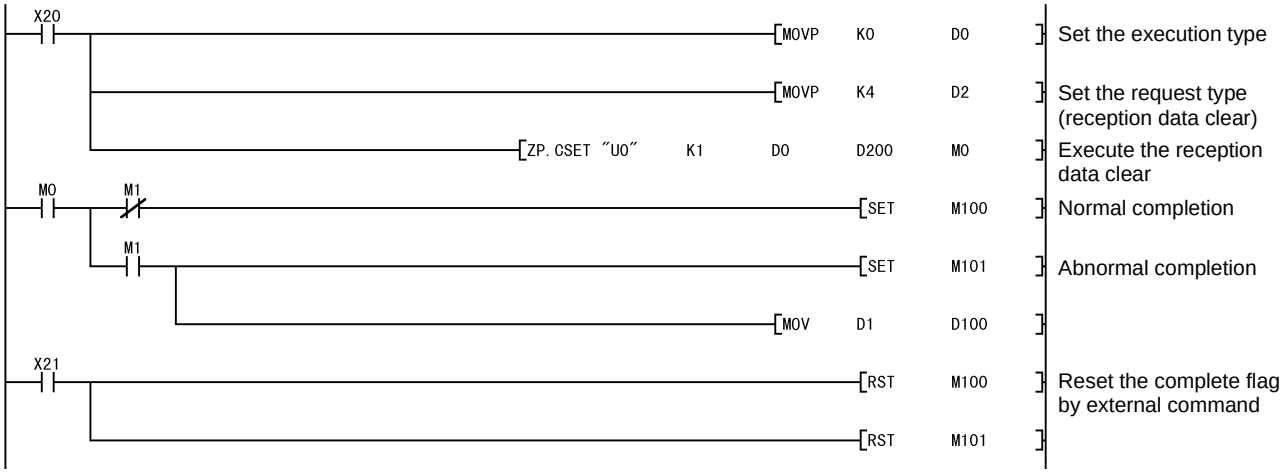
(1) If the dedicated instruction is abnormally completed, the error flag (SM0) turns on and the error code is stored in SD0.
See the following manuals according to the error code, and check/take action according to the error.

<Error code>
4FFFH or less: QCPU User's Manual
(Hardware Design, Maintenance and Inspection)
7000H or more: Section 10.2 of the User's Manual (Basic)

Program example

This is an example of a program that clears reception data on the Q series C24 side.

It is assumed that the input/output signals of the Q series C24 are X/Y00 to X/Y1F.



10 TROUBLESHOOTING

This chapter explains the definitions of errors that may occur during data communication between the Q series C24 and external devices, and the corrective actions.

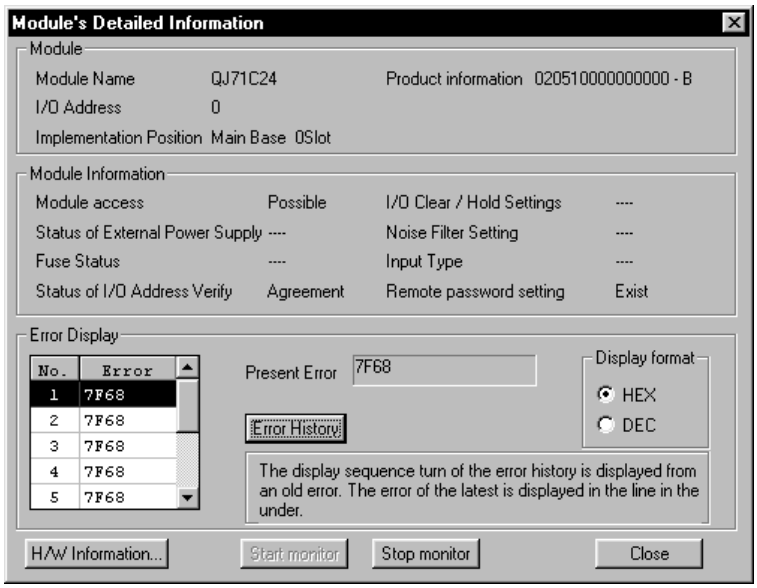
10.1 Checking the Status of the Serial Communication Module

10.1.1 Checking the LED ON status, communications error status, and switch setting status of the serial communication module

This section explains how to check the status of communication between the Q series C24 and external devices, the transmission status of the Q series C24, and the switch setting status of the Q series C24.
When a communication problem occurs, check the error status using one of the following procedures:

(1) Checking the module status and error codes in the detailed module information screen of the GX Developer diagnostic functions

[Startup procedure]
GX Developer → [Diagnostics] → [System monitor] →
Module's Detailed Information



(For SW6D5C-GPPW-E)

10

[Displays]

- Module

  The following information is displayed:

  Module name : The name of the module installed
  I/O Address : The start input/output signal (number) of the target module
  Implementation Position: The slot position where the module is mounted
  Product information : Product information
  ∗ The last character of the product information indicates the function version of the module.
  (Example) If the last character is "B," it means that the module is of function version B.

- Unit access (Module access)

  Displays access permissions when the Ready signal (X1E) is turned on and the WDT error signal (X1F) is turned off.

- Status of I/O Address Verify

  Displays whether or not the module for which the user set the parameters matches the module installed.

- Remote password setting status

  Displays the setting status of the remote password.

- Present Error

  Displays the error code of the latest error occurrence.

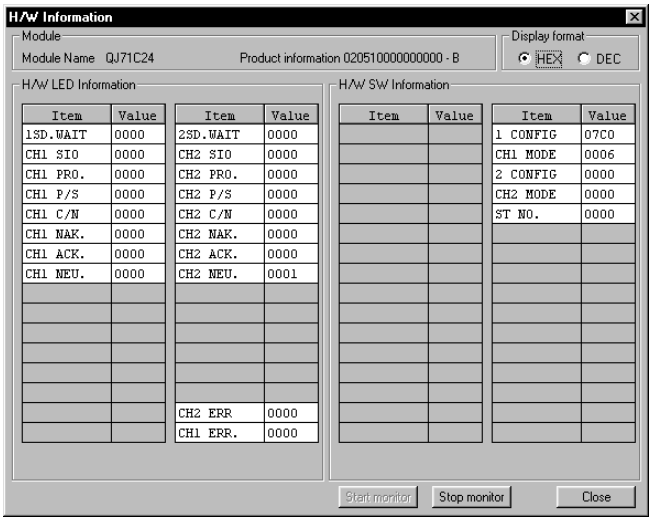
- Error Display

  Displays the error codes for any errors that have occurred in any of the functions being used.

(2) Checking using the hardware information screen of the GX Developer diagnostic functions

[Startup procedure]

GX Developer → [Diagnostics] → [System monitor] →
Module's Detailed Information → H/W Information



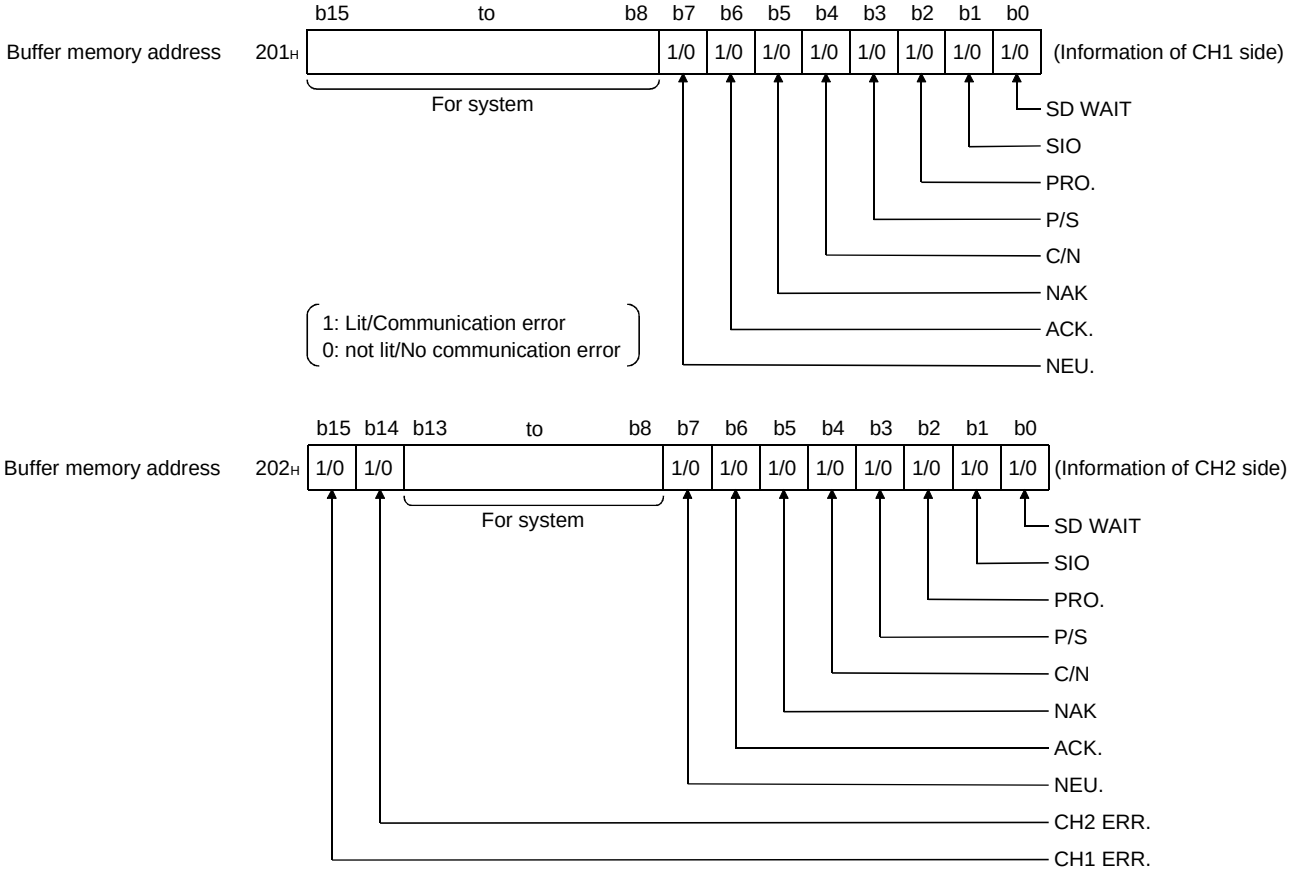
(For SW6D5C-GPPW-E)

[Displays]

1) H/W LED Information Right side (Left side: CH1 information/
Right side: CH2 information)

Displays the transmission status and the communications error status of the Q series C24.

(Displays 201H/202H of the buffer memory.)



2) H/W SW Information Parameter

The switch information of the Q series C24 is displayed.

Numbers 1 through 5 correspond to switches 1 through 5 shown in Section 4.5.2.

(See Section 4.5.2 of the User's Manual (Basic).)

(3) Checking by QSCU

Display the "Monitor others" screen.
For details on display screens, see Section 8.6.9 of the User's Manual (Basic).

(4) Description of LED ON status and communications error status

No.	Status signal name	Description	Description when ON (when LED is turned on (1))	Description when OFF (when LED is turned off (0))	Initial state	Related protocol		
						MC	Non procedure protocol	Bidirectional protocol
1	SD WAIT	Transmission wait status	Waiting for data transmission	Data transmission start	OFF	○		
2	SIO	SIO error status	Overrun or framing error occurred.	Normal	OFF	○		
			OS area is full. ＊ Received data was deleted.		OFF	—	○	
3	PRO.	Communication protocol error status	Error occurred.	Normal	OFF	○	—	
4	P/S	Status of parity error or sum check error	Error occurred.	Normal	OFF	○		
5	C/N	Access status with the PLC CPU	(＊1)	Normal	OFF	○	—	
6	NAK	Abnormal completion status	Abnormal completion transmission	Normal completion transmission	OFF			
7	ACK.	Normal completion status	Normal completion transmission	Abnormal completion transmission	OFF			
8	NEU.	Neutral status ＊ Waiting to receive command	Neutral	Command reception	(＊2)			
9	CH2. ERR	Error occurrence status on CH2 side	Switch setting error Mode switching error Transmission error Reception error On-demand error	Normal	OFF	○		
10	CH1. ERR	Error occurrence status on CH1 side			OFF			

＊1 C/N turns on in the following cases:

- An external device issued a data read request to the PLC CPU when write during RUN is set to prohibit in the switch settings by GX Developer (see Section 4.5.2).

  ＊ For functions that cannot be used when write during RUN is set to prohibit, see the explanation section in each command list of the Reference Manual.
- When an error has occurred during access between the Q series C24 and the PLC CPU.

＊2 NEU. is valid when a target interface is set to use the MC protocol.
When the target interface is set to other than the MC protocol, the status of NEU. is off.

(a) When a communication error occurs, take corrective action according to Section 10.3.

(b) The initial status of the LED ON and communications error indicates the status when the Q series C24 starts up by turning on the power or resetting the PLC CPU.

(c) Each of the communications error status, C/N to SIO, CH1 ERR. and CH2 ERR., turns on when an error occurs, and keeps its on-status even after the communication returns to normal.
The PLC CPU can check the aforementioned LED ON status and communications error status, and initialize any error information using read/write to the buffer memory of the Q series C24 and input/output signals. Initialize the error information according to Section 10.1.2.

(d) NAK to NEU. (No. 6 to 8) turn on/off depending on the status.

(e) SD WAIT turns on when data cannot be sent to the external device by the transmission control of the Q series C24 (waiting for data transmission).
- When transmission cannot be started.
- When a transmission pause request is received during data transmission. (DSR signal is off, reception by DC3)
SD WAIT turns off when transmission becomes possible and data transmission is started/resumed.

10.1.2 Initializing error information of the serial communication module

This section explains the ERR. LED ON factors and the error information initialization (clear) for the Q series C24.

(1) ERR. LED ON factors

When any of the following errors occurs, its error code is stored in the buffer memory corresponding to the interface (CH) where the error occurred, and the ERR. LED turns on.

Cause of error	Error code storage buffer memory			Applicable protocol		
	Address		Name	MC	Non-procedure protocol	Bidirectional protocol
	CH1	CH2				
Switch setting error Mode switching error	203H		Switch setting error, mode switching error storage area	○	○	○
On-demand execution error	256H	266H	On-demand execution result storage area	○	×	×
Data transmission error	257H	267H	Data transmission result storage area	○	○	○
Data reception error	258H	268H	Data reception result storage area	○	○	○
MC protocol transmission error	025AH	026AH	MC protocol transmission error code	○	×	×
Monitoring device error	2205H	2305H	PLC CPU monitoring function execution result	○	○	○

(2) Turning off the ERR. LED and initializing the error information by QSCU

Display the "Monitor" screen.
Performing the initialization operation for the error information on the "Monitor" screen will turn off the ERR. LED of the Q series C24, and the error information stored is initialized.
For details on how to display this screen, see Section 8.6.10 of the User's Manual (Basic).

(3) Turning off the ERR. LED and initializing the error information by the PLC CPU

(a) Input signals used to notify of error occurrences and output signals used to initialize the error information

I/O signal		Name of status information	Description/function
Input signal	XE	Error occurrence on CH1 side	Turns on upon error occurrence in CH1 interface.
	XF	Error occurrence on CH2 side	Turns on upon error occurrence in CH2 interface.
Output signal	YE	CH1 Error information initialization request	Turns on when initializing error information of interface on CH1 side.
	YF	CH2 Error information initialization request	Turns on when initializing error information of interface on CH2 side.

* Initialization of error information is continuously performed when output signal (YE/YF) is on.

POINT

Error information on the CHn side can be initialized by an off request to the LED off request area (address 1H) of the buffer memory. By using output signals YE to YF, the error codes stored in the above buffer memory can also be initialized (cleared).

(b) Initializing communication error information by writing

Communication error information can be initialized by writing "1" to the corresponding bit in the buffer memory addresses 0H to 1H.

* The displayed LEDs and communication error information may be turned on/off in the following cases:
  - NEU. to NAK turn on/off depending on the status.
  - C/N to SIO turn on when errors occur and keep the ON-status even after the operation returns to normal.

1) LED and communications error information initialization request area (address: 0H to 1H)

The contents of the error information corresponding to each bit in this request area are the same as those for the LED ON/communication error status storage area (address: 201H to 202H).

For more details, see Section 10.1.1 (1).

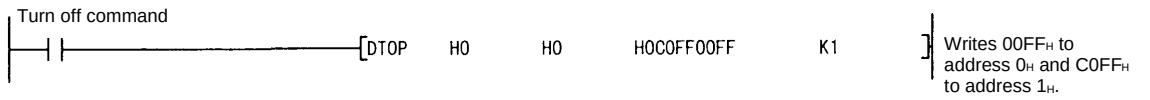
The following describes the correspondence between the LED OFF request areas and the LED ON status storage areas:

- LED and communication error information initialization request area (address: 0H) LED ON and communications error status storage area (address: 201H)
- LED and communications error information initialization request area (address: 1H) LED ON and communications error status storage area (address: 202H)

2) Example of a program for turning off displayed LEDs

The following shows an example of a program that issues an initialization request for all the communication error information. (Input/output signals X/Y00 to X/Y1F of QC24)

● Example of TO instruction



POINT

(1) Initialization requests are valid only when write operation is performed.
The initialization requests clear all data in the LED ON and communication error information storage area (201H to 202H) at the same time.
Furthermore, when initialization of error information on the CH1 and CH2 sides is requested, XE and XF also turn off.

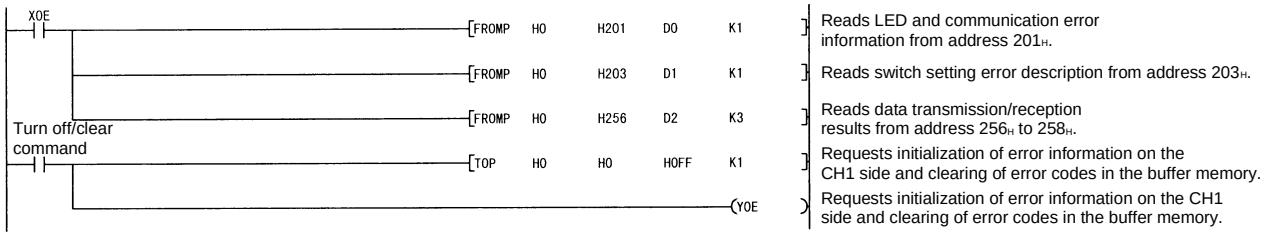
(2) Data written to the buffer memory address 0H to 1H is cleared after initialization processing.

(3) If errors persist even after completion of the initialization processing, the corresponding communication error information is stored again and the corresponding bit in the LED ON and communications error status storage area (201H to 202H) turns on (1).

(c) Examples of programs that initialize displayed LED and communication error information

The following shows examples of a program that reads error codes when errors described in (1) above occur in an interface on the CH1 side and initializes the displayed LED and communication error information.
Incorporate the necessary part of the program.
(Input/output signals X/Y00 to X/Y1F of the Q series C24)

1) When data is communicated using the MC protocol



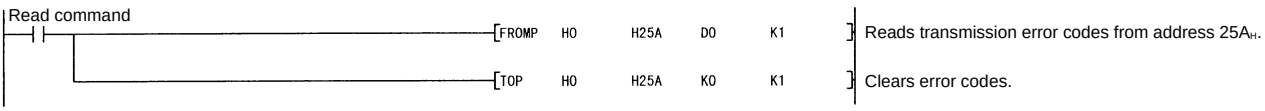
Check the error codes and take corrective action according to Section 10.2.

2) When data is communicated using the non procedure or bidirectional protocol

Check the error codes and take corrective action according to Section 10.2.

REMARK

When data is communicated using the MC protocol, the displayed ERR. LED may not be turned on if the Q series C24 sends an NAK message to the external device in response to the command message.
Error codes (see Section 10.2) corresponding to the error content when the NAK message is sent back to the external device are stored in the following areas. (when communicating with an A compatible 1C frame, the error codes differ from the transmission error code.)
When checking error codes transmitted by the PLC CPU, incorporate the following program (in case of the interface on the CH1 side).



Check the error codes and take corrective action according to Section 10.2.

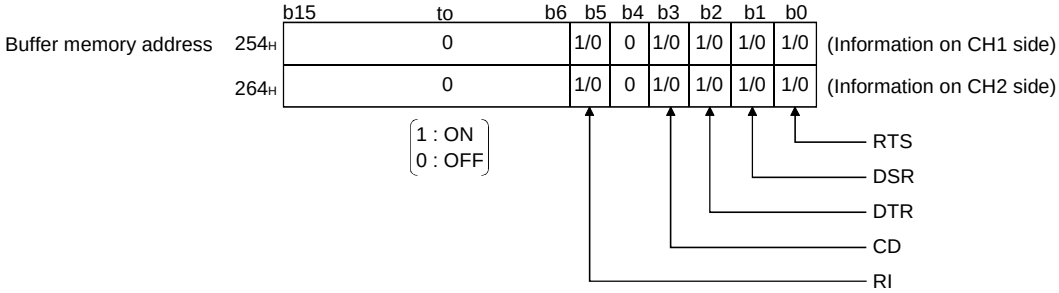
10.1.3 Reading the RS-232 control signal status

This section explains how to read the control signal status stored in the buffer memory during communication using RS-232 interface.
When QSCU is used, check the status using the "Transmission control and others monitor" screen (see Section 8.6.3).

When a transmission problem occurs, read operation is executed to check the signal on/off status of the RS-232 interface.

(1) RS-232 control signal status storage area (address: 254H, 264H)

The status of the RS-232 signals is stored in buffer memory addresses 254H and 264H as follows:



REMARK

(1) For more details on signals for RS-232, see Section 3.2.1.

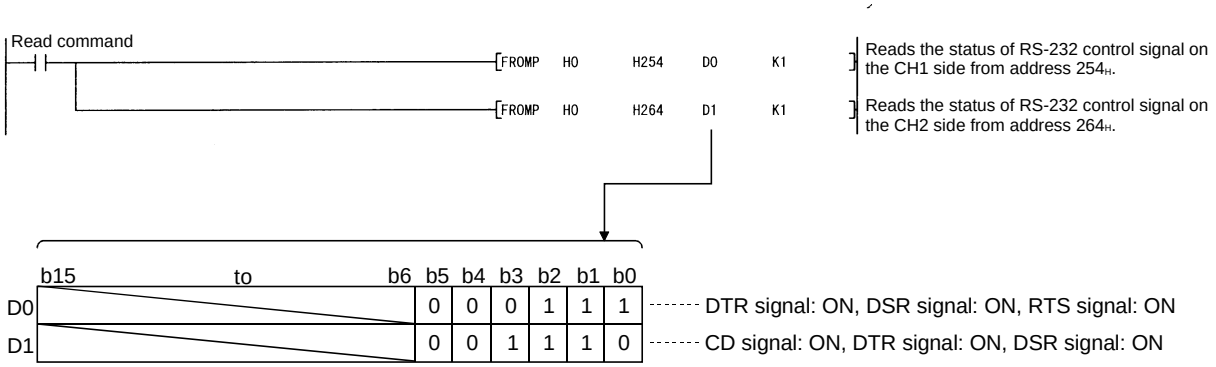
(2) Signals output from the Q series C24 side (RTS and DTR) are controlled by the operating system (OS) of the Q series C24.
They cannot be directly controlled by the sequence program.

(3) There is a maximum delay of 100 ms in signal status stored in the buffer memory above.

(2) Example of a program that reads from RS-232 control signal status storage area

The following shows an example of a program that reads the RS-232 control signal status.
(input/output signals X/Y00 to X/Y1F of the Q series C24)

● Example of FROM instruction



10.1.4 Reading the data communication status (Transmission sequence status)

This section explains how to read the current status of the data communication using the MC protocol stored in the buffer memory.
When QSCU is used, check the status using the "MC protocol monitor" screen (see Section 8.6.4).

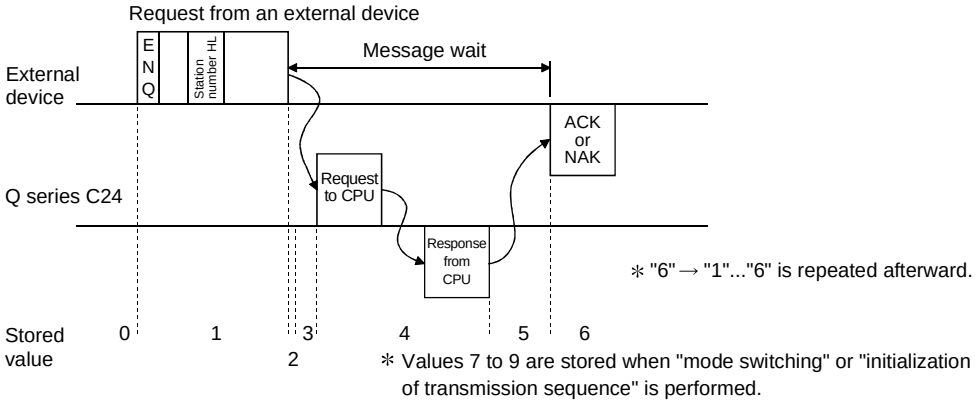
When a transmission problem occurs, read operation is executed to check the status of the data communication using the MC protocol.

(1) Transmission sequence status storage area (address: 255H and 265H)

The status of data communication using the MC protocol is stored as a numerical value in buffer memory addresses 255H and 265H.

Buffer memory address		b15 to b0	
	255H	0 to 9	(Information on the CH1 side)
	265H	0 to 9	(Information on the CH2 side)

The following shows the correspondence between the numerical values in the transmission sequence status storage area and the data communication status.



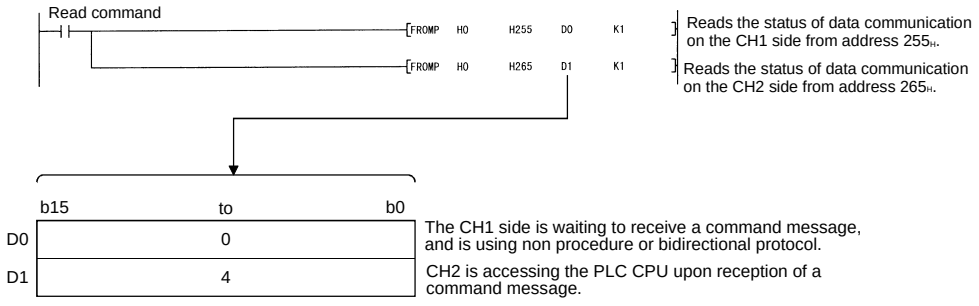
REMARK

When the target interface is not set to use the MC protocol, "0" is stored in the transmission sequence status storage area.

(2) Example of a program that reads from transmission sequence status storage area

The following shows an example of a program that reads from the transmission sequence status storage area.
(input/output signals X/Y00 to X/Y1F of the Q series C24)

● Example of FROM instruction



10.1.5 Reading the switch setting status

This section explains how to read the setting status of various switches of the Q series C24 stored in the buffer memory.
When QSCU is used, check the status in the "Monitor others" screen (see Section 8.6.9).

When a switch setting error occurs, read operation is executed to check the status of various switches of the Q series C24.
The Q series C24 reads the switch settings designated in GX Developer at startup from the PLC CPU and operates according to the settings.

REMARK

(1) The communication protocol and transmission settings can be changed at mode switching (see Chapter 15 of the User's Manual (Application)).

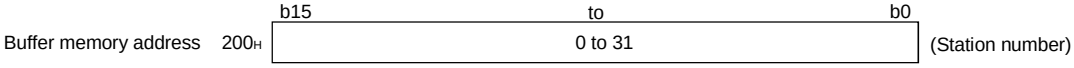
(2) If switch setting errors occur after mode switching, check the setting changed by the user by performing read operations as described in Section 10.1.6.

(3) For the description of the communication protocol, station number, and transmission settings, see Section 4.5.

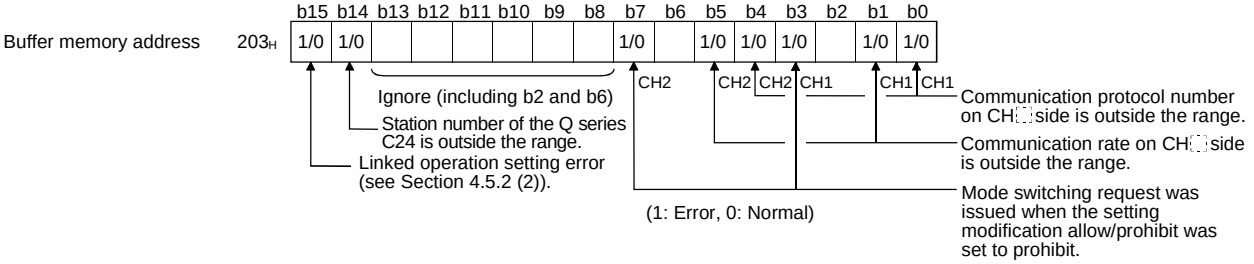
(1) Setting status storage area

The switch settings by GX Developer and setting error information are stored in different areas of the buffer memory shown below.

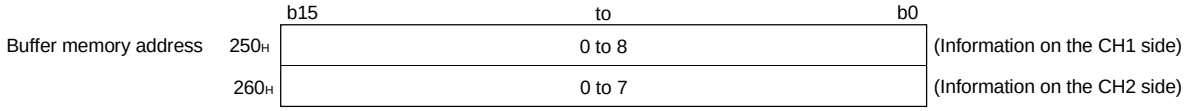
1) Station number setting status storage area (address: 200H)



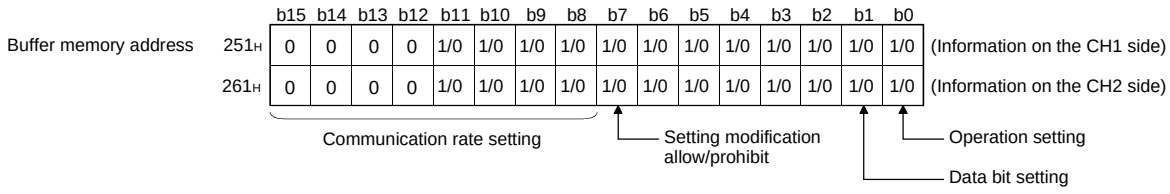
2) Switch setting error/mode switching error storage area (address: 203H)



3) Communication protocol setting storage area (address: 250H and 260H)



4) Transmission setting status storage area (address: 251H and 261H)



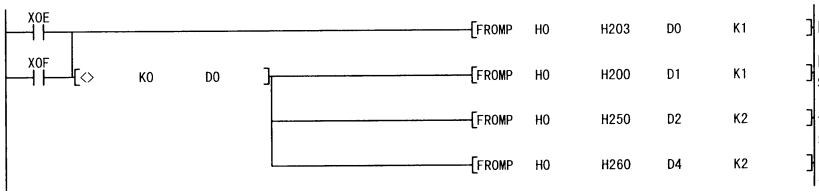
(2) Example of a program that reads from the setting status storage area

The following shows an example of a program that reads the setting of various switches of the Q series C24 from the setting status storage area.

For details on XE and XF of the input/output signals used in the program, see Section 10.1.2 (3).

(input/output signals X/Y00 to X/Y1F of the Q series C24)

● Example of FROM instruction



Reads error description from address 203H.

Reads station number setting and switch setting description from address 200H.

Reads communication protocol setting and transmission setting description on the CH1 side from addresses 250H to 251H.

Reads communication protocol setting and transmission setting description on CH2 from addresses 260H to 261H.

Restarts the Q series C24 after checking the error code and resetting switches.

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0	
D0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	Error description (1: Communication protocol number setting error)
D1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	Setting station number of the Q series C24 (0).
D2	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	CH1 side: Communication protocol setting number (9).
D3	0	0	0	0	0	1	0	1	0	0	0	0	1	0	1	0	CH1 side: (transmission setting description)
D4	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	CH2 side: Communication protocol setting number (1).
D5	0	0	0	0	0	1	0	1	0	1	1	0	1	0	1	0	CH2 side: (transmission setting description)

Displays communication protocol number setting error status on the CH1 side

10 - 12

10.1.6 Reading the switch setting status for the current operation

This section explains how to read the switch setting status stored in the buffer memory that are relevant to the current operation of the Q series C24.
When QSCU is used, check the status in the "Transmission control and others monitor" screen (see Section 8.6.3).

When a switch setting error occurs after mode switching (see Chapter 15 of the User's Manual (Application)), read operation is executed to check settings changed by the user.
The switch settings by GX Developer can be changed at mode switching and if the setting at mode switching is incorrect, a switch setting error occurs.

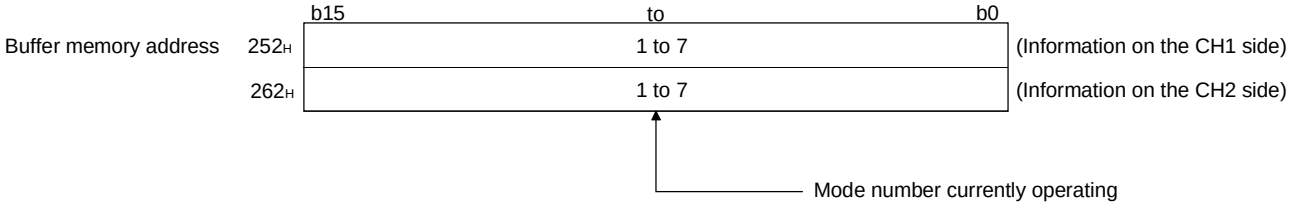
REMARK

- The status of the switch settings by GX Developer can be checked by performing read operations as described in Section 10.1.5.
- For the description of the communication protocol and transmission settings, see Section 4.5.

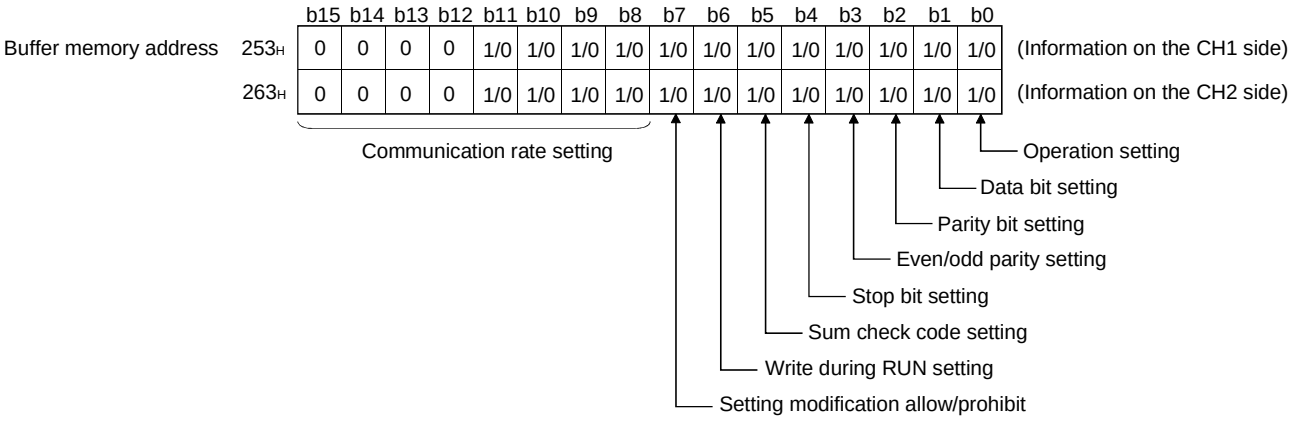
(1) Operation mode status storage area

The status of the switch settings for the current operation of the Q series C24 is stored in the areas of the buffer memory shown below.

1) Communication protocol setting status storage area (addresses: 252H and 262H)



2) Transmission setting status storage area (address : 253H, 263H)



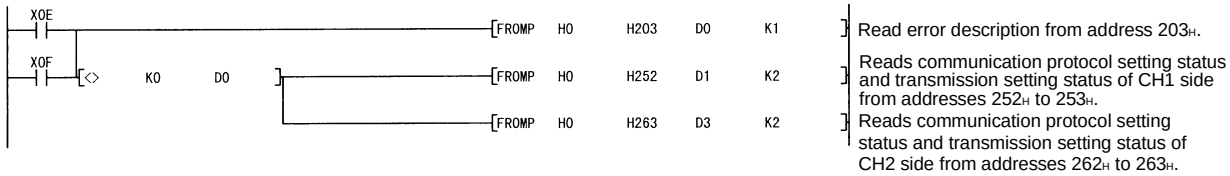
(2) Example of a program that reads from the current setting status storage area

The following shows an example of a program that reads from the switch setting status storage area for current operation of the Q series C24.

For details regarding XE and XF of the input/output signals used in the program, see Section 10.1.2 (3).

(input/output signals X/Y00 to X/Y1F of the Q series C24)

● Example of FROM instruction



After checking error codes and changed setting values, designate the correct setting values and switch mode.

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0	
D0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	Communication protocol Error description (2: Communication rate error)
D1	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	CH1 side: Setting communication protocol number 6 (transmission setting description)
D2	0	0	0	0	1	1	1	1	0	0	0	0	1	0	1	0	
D3	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	CH2 side: Setting communication protocol number 1 (transmission setting description)
D4	0	0	0	0	0	1	0	1	0	1	1	0	1	0	1	0	

While the CH1 side is set to the non procedure protocol and the CH2 side is set to the MC protocol (format 1), this indicates the communication rate setting error on the CH1 side.

10 - 14

10.2 Error Code Tables

The following shows the error codes, error contents, and corrective action for errors that are generated during communications between the Q series C24 and an external device.
For errors without a corresponding LED entered to errors generated with the MC protocol communication, only the "NAK" LED is turned ON.

10.2.1 QnA compatible 2C/3C/4C frame communications/Flash ROM access error code table

The following shows the error codes, error contents, and corrective action for errors generated during communications using the QnA compatible 2C/3C/4C frame, and during Flash ROM access.
("*" in the table is the error code when the target CPU is not a Q/QnACPU.)

Error code (Hexa-decimal)	Error	Error Contents	Corres-pondence signal name	Corrective action	Protocol		
					MC	Non Proce-dure	Bidire-ctional
3E8H to 3FFFH	—	(Error detected by the CPU)	—	• See Troubleshooting of the QCPU (Q mode) maintenance and inspection user's manual and take corrective action.	○		
4000H to 4FFFH	—	(Error detected by the CPU)	—	• See Appendix of the QCPU (Q mode) maintenance and inspection user's manual (details) and take corrective action.	○		
7103H	PLC access error	• Cannot communicate with the Q series C24 CPU.	C/N	• Make the watchdog timer (timer 1) time longer. • Check if the CPU can communicate in communication protocol No. "F".	○		
7140H *	Request data error	• Number of request points exceeds the range for the command. • A word device was designated in a bit units command. • The last device No. exceeds the range. (Given device last No. ≧ Designated head device No. + Designated number of points)	PRO	• Check and correct the external device transmit message and restart data communications.	○		
7142H *	Device name error	• A device that cannot be designated by the given command was designated.	PRO	• Check and correct the external device transmit message and restart data communications.	○		
7143H *	Device No. error	• The head device No. is out of range.	PRO	• Check and correct the external device transmit message and restart data communications.	○		
7144H *	Monitor data write error	• Monitoring was requested before the device to be monitored was written.	PRO	• Write the device to be monitored before issuing a monitor request.	○		
7145H *	Monitor PLC No. error	• The written PLC No. and PLC No. in the monitor request are different.	C/N	• Rewrite the monitor data.	○		
7146H *	Monitor CPU model name error	• The written CPU model name and the CPU monitor name in the monitor request are different.	C/N	• Rewrite the monitor data.	○		
7147H *	Written number of monitoring points overrun error	• The written number of monitoring points exceeds the designated range.	PRO	• Check and correct the external device transmit message and restart data communications.	○		
7148H *	Extension R block No. error	• A nonexistent extension file register block No. was designated. • A block No. being used as an extension comment area, sampling trace area, or status latch area was designated.	PRO	• Correct the designated block No. and restart data communications.	○		

Error code (Hexa-decimal)	Error	Error Contents	Corres-pondence signal name	Corrective action	Protocol		
					MC	Non Proce-dure	Bidire-ctional
714A$_H$ *	Cannot execute a command during RUN	• A write command was designated when "Disable write during RUN" was set. • Parameter or sequence program was written during RUN.	C/N	• Change the setting to "Enable write during RUN" and restart data communications. • Stop the CPU and restart data communications.	○		
714E$_H$ *	Monitor network No. error	• The written monitor network No. and the monitor request network No. are different.	C/N	• Check and correct the other station access valid module No. in the network parameters. • Rewrite the monitor data.	○		
7151$_H$	PLC No. designation error	• A PLC No. other than "FF" or "0 to 64(00$_H$ to 40$_H$)" was designated.	C/N	• Check and correct the external device transmit message and restart data communications.	○		
7153$_H$	Frame length error	• The received message length has exceeded the allowable range.	CHn ERR.	• Review the transmission message. • Correct the message format so the number of access points is within the allowable range.	○		
7155$_H$	Unwritten monitor data error	• Monitoring was requested before monitor data was written.	PRO	• Write the device to be monitored before issuing a monitor request.	○		
7160$_H$	PLC access error	• CPU model name cannot be confirmed.	C/N	• If there is an error in the CPU, remove the CPU error and restart data communications.	○		
7164$_H$	Request error	• Either the request or the device designation method is wrong.	—	• Check the transmission message/request from the external device, make the necessary corrections, and send again.	○		
7167$_H$	Cannot execute a command during RUN	• A write command was designated when "Disable write during RUN" was set.	C/N	• Change the setting to "Enable write during RUN" and restart data communications.	○		
7168$_H$		• A command that cannot be executed during RUN was designated.	C/N	• Stop the CPU and restart data communications.	○		
7169$_H$	CPU error	• Cannot communicate normally with the CPU.	C/N	• If there is an error in the CPU, remove the CPU error and restart data communications.	○		
716D$_H$	Monitor data write error	• Monitor data was not written using QnA compatible 2C/3C/4C frame.	PRO	• Rewrite monitor data.	○		
716E$_H$		• Monitor data was not written using A compatible 1C frame.	PRO				
7170$_H$	A compatible 1C frame error	• Number of access points exceeded the range.	PRO	• Check and correct the external device transmit message and restart data communications.	○		
7171$_H$		• A device that cannot be designated was designated.	PRO		○		
7172$_H$		• Written number of monitoring points is incorrect. For example, [0] was designated.	PRO		○	○	○
7173$_H$	Monitor data write error	• Monitor data was written for a CPU other than a Q/QnACPU using QnA compatible 2C/3C/4C frame.	PRO	• Write the monitor data and use the A compatible 1C frame to a CPU other than a Q/QnACPU.	○		
7E06$_H$	Buffer memory address setting error	• Transmit/receive buffer memory addresses are in the special applications area.	—	• Change the buffer memory addresses so that they are outside the special applications area.			
7E40$_H$	Command error	• A nonexistent command or subcommand was designated.	PRO	• Check and correct the external device transmit message and restart data communications.	○		
7E41$_H$	Data length error	• A data length exceeding the number of points that can communicate during random read/write was designated.	PRO	• Check and correct the external device transmit message and restart data communications.	○		

10 - 16

Error code (Hexa-decimal)	Error	Error Contents	Corres-pondence signal name	Corrective action	Protocol		
					MC	Non Proce-dure	Bidire-ctional
7E42H	Error count error	• Number of requested points exceeds the range for the command.	PRO	• Check and correct the external device transmit message and restart data communications.	○		
7E43H	Device error	• A nonexistent device was designated. • Device that cannot be specified by the corresponding command was designated.	PRO	• Check and correct the external device transmit message and restart data communications.	○		
7E44H	Timer 1 time-out error	• A response message was not returned within the response monitoring time (timer 1) monitoring time.	C/N	• Make the timer 1 monitoring time longer. • When accessing another station's CPU, check if the routing parameters match.	○		
7E47H	Continuous request error	• The next request was received before a response message was returned for the preceding request.	PRO	• Do not issue continuous requests from the external device. • Set the timer 1 monitoring time to the external device time-out time.	○		
7E4FH	Device point count error	• Access point count is incorrect.	PRO	• Check and correct the external device transmit message and restart data communications.	○		
7E50H	User frame No. designation error	• A user frame No. outside the range was designated.	PRO	• Check and correct the external device transmit message and restart data communications. • Recheck the frame No..	○		
7E51H	Unwritten user frame error	• An unwritten user frame No. was designated.	PRO	• Write the frame beforehand. • Change the frame No. and restart data communications. • Recheck the frame No..	○		
7E52H	User frame overwrite error	• A written frame No. overwrite request was issued.	PRO	• Change the write destination to an unwritten frame No. • When overwriting, delete the given No. beforehand.	○		
7E53H	User frame access data error	• A nonexistent command was designated in a subcommand. • Byte count exceeding the number of bytes that can be requested was designated.	PRO	• Check and correct the external device transmit message and restart data communications.	○		
7E54H	Modification allowed error	• Flash ROM write allow/prohibit designation from QSCU is set to OFF. • At the switch setting on GX Developer, modification allowed switch was set to OFF.	PRO	• Set to ON at QSCU. • Set to ON at GX Developer.	○	○	○
7E55H	User frame data error	• There is an error in the user frame variable data.	PRO	• Check and correct the external device transmit message and restart data communications.	○	○	
7E57H	Flash ROM write error	• Cannot write to Flash ROM normally.	PRO	• Re-execute the write operation. If the error is generated again, replace the module.	○		
7E58H	Mode modification error	• There was an error in the mode No. or transmission specification designated contents when changing the mode.	PRO	• Check and correct the contents of the external device transmit message and restart data communications. • Recheck the switch setting on the Q series C24.	○	○	○

Error code (Hexa-decimal)	Error	Error Contents	Corres-pondence signal name	Corrective action	Protocol		
					MC	Non Proce-dure	Bidire-ctional
7E5FH	I/O number error on requested module	• I/O number of requested module is incorrect.	—	• Correct the I/O number of the module to which data is sent.	○	○	
7E60H	Device monitoring duplicate registration error	• PLC CPU monitoring registration was performed twice.	—	• Cancel the PLC CPU monitoring and perform the PLC CPU monitoring registration again.	○	○	
7E61H	Cycle time units range error	• Setting value of cycle time units is out of range.	—	• Correct the setting value of the cycle time units.	○	○	
7E62H	PLC CPU monitoring function error	• Setting value of PLC CPU monitoring function is out of range.	—	• Correct the setting value of the PLC CPU monitoring function.	○	○	
7E63H	Transmission measure setting error	• Setting of transmission measure of the PLC CPU monitoring is incorrect.	—	• Correct the setting value of the transmission measure.	○	○	
7E64H	Registration point range error	• Registration point (word/bit) is out of range.	—	• Correct the setting value of the registration point (word/byte)	○	○	
7E65H	PLC CPU abnormal monitoring number error	• Setting value of the PLC CPU abnormal monitoring is out of range.	—	• Correct the setting value of the PLC CPU abnormal monitoring.	○	○	
7E66H	Monitoring condition error of monitoring device	• Setting value of transmission condition is out of range.	—	• Correct the setting value of the transmission condition.	○	○	
7E67H	CPU abnormal monitoring setting value error	• Setting value (fixed value) of CPU abnormal monitoring is out of range.	—	• Correct the setting value (fixed value) of the CPU abnormal monitoring.	○	○	
7E68H	Transmission condition range error of monitoring device	• Setting value of transmission condition (condition agreement transmission) is out of range.	—	• Correct the setting value of the transmission condition (condition agreement transmission).	○	○	
7E69H	CPU abnormal monitoring setting value error	• Setting value (fixed value) of CPU abnormal monitoring is out of range.	—	• Correct the setting value (fixed value) of the CPU abnormal monitoring.	○	○	
7E6AH	Monitoring device read point range error	• Read point of monitoring device is out of range.	—	• Correct the setting value of the read point of the monitoring device.	○	○	
7E6BH	CPU abnormal monitoring setting value error	• Setting value (fixed value) of CPU abnormal monitoring is out of range.	—	• Correct the setting value (fixed value) of the CPU abnormal monitoring.	○	○	
7E6CH			—		○	○	
7E6DH			—		○	○	
7E6FH	Modem connection error	• Modem is connected to an incorrect channel.	—	• Correct the CH to which notification is sent.	○	○	
7E70H	CPU error	• The communication with the CPU could not be performed normally.	C/N	• If there is an error in the CPU, eliminate the error on the CPU side and communicate again.	○	○	
7EC3H	Double send request error	• A send request was performed while another send request was being processed.	—	• Interlock (handshake) the send requests.		○	○
7EC4H	Transmission data count error	• Data larger than the transmit buffer size was transmitted.	—	• Make the transmission data count smaller than the transmit buffer size. • Make the non procedure protocol transmit buffer size larger.		○	○
7EC5H	Flash ROM access error	• Write to Flash ROM was requested when the setting modification enable/disable switch in the GX Developer was set to OFF.	—	• When writing to Flash ROM, set switch shown left of the given interface to ON and restart the Q series C24.	○	○	○
7EC6H		• There is an error in the Flash ROM read/write request contents.	—	• Check the read/write request data and designate the correct data.	○	○	○

10 - 18

Error code (Hexa-decimal)	Error	Error Contents	Corres-pondence signal name	Corrective action	Protocol		
					MC	Non Proce-dure	Bidire-ctional
7F01H	Buffer full error	• The next data was received before processing of the previous data was completed.	—	• Increase the transmission time by performing handshake with the external device, etc.	○		○
		• Multiple requests was simultaneously issued for one channel.		• Perform handshake with the request source external device.	○	○	○
7F20H	ASCII → BIN conversion error	• An ASCII code that cannot be converted to binary code was received.	PRO	• Check and correct the external device transmit message and restart data communications.		○	○
		• An odd number of bytes of data was received during data communications using ASCII - BIN conversion.		• When communicating using ASCII - BIN conversion, always transmit the data in even number bytes units.			
7F21H	Receive header area error	• There is an error in the command (frame) part.	PRO	• Check and correct the external device transmit message and restart data communications.	○		
		• An ASCII code that cannot be converted to binary code was received.					
7F22H	Command error	• A nonexistent command or device was designated. • The remote password length is wrong.	PRO	• Check and correct the external device transmit message and restart data communications.	○		
7F23H	MC protocol message error	• There is no data (ETX, CR-LF, etc.) following the character area, or designation was incorrect.	PRO	• Check and correct the external device transmit message and restart data communications.	○		
7F24H	Sum check error	• The sum check calculated by the Q series C24 and the received sum check are not the same.	P/S	• Recheck the external device sum check.	○	○	
7F25H	Data length error	• The length of the received data exceeds the receive area size.	CHn ERR.	• Correct the "data length" that is transmitted from the external device. • Change the "word/byte units" set by the Q series C24 to byte units. • Increase the receiving area of the Q series C24.			○
7F26H	Command error	• Another command was received before an unlock processing while the remote password is registered.	CHn ERR.	• Perform the communication after the unlock processing is normally completed.	○		
7F30H	BIN → ASCII conversion error	• The send data contains data that cannot be converted to ASCII code.	—	• Check and correct the send data.		○	○
7F31H	Simultaneous transmission error	• The Q series C24 and an external device started transmitting simultaneously.	—	• Process by agreement with the external device. • When necessary, change the simultaneous transmission data valid/invalid designation setting by QSCU. (buffer memory addresses 9BH/13BH)			○
7F40H	Time-out error	• No reception watchdog timer (timer 0) time-out occurred.	PRO	• Check if data was dropped from the receive data. • Check if DTR control, etc. interrupted reception.	○	○	○
7F41H		• Response watchdog timer (timer 1) time-out occurred.	—	• Check the status of the message transmission destination and restart data communications, as required.	○		○
7F42H		• Transmit watchdog timer (timer 2) time-out occurred.	—	• Check if DTR control, etc. interrupted transmission.	○	○	○
7F67H	Overrun error	• The Q series C24 received the next data before it completed receive processing of the previous data.	SIO	• Decrease the data transmission rate and restart data communications. • Check whether a temporary stop has occurred in the station in which the Q series C24 is installed. (For the QCPU this can be checked using special register SD1005.) If a temporary stop has occurred, remove its cause.	○	○	○

10 - 19

Error code (Hexa-decimal)	Error	Error Contents	Corres-pondence signal name	Corrective action	Protocol		
					MC	Non Proce-dure	Bidire-ctional
7F68H	Framing error	• Data does not match the stop bit setting.	SIO	• Match the Q series C24 and external device settings.	○	○	○
7F69H	Parity error	• Data does not match the parity bit setting.	P/S	• Match the Q series C24 and external device settings.	○	○	○
7F6AH	Buffer full error	• OS receive buffer overflowed and receive data was skipped.	SIO	• Use DTR and DC control and perform data communications so that the buffer does not become full. (Perform RS · CS control when the modem function is used.) • If the Read Request signal was turned ON, execute read immediately.	○	○	○
7F6BH	CD signal control error	• Data was received when CD signal is OFF when "CD terminal check enabled" was designated.	CHn ERR.	• Recheck the CD signal control of the external device. (Send while the CD signal is ON.) • Set "no CD terminal checking" and perform communication.	○	○	○
7F6CH	Transmission error	• Data cannot be sent because the line is not connected.	CHn ERR.	• Transmit data after line connection processing on the interface side that uses the modem function.	○	○	○
7FE6H	Processing disabled	• Remote passwords do not match.	—	• Check the remote password and communicate again.	○		
7FE7H		• The remote password is not registered. • The remote password processing command was received on the interface side where the modem function is not used. • The GX Developer connection is selected in the communication protocol setting on the corresponding CH.	CHn ERR.	• A remote password processing command is not necessary when a remote password is not registered. • Perform a remote password unlock processing through GX Developer. Alternatively, change the communication protocol setting of the corresponding CH to the MC protocol.	○		
7FE8H		• The number of remote password disagreements exceeded the value designated at the address 200DH.	CHn ERR.	• Clear the storage area of the cumulative number of abnormal completions of unlock processing (address: 22FCH) to 0.	○		
7FF0H	Dedicated instructions simultaneous execution error	• Executed dedicated instructions simultaneously.	—	• Do not use dedicated instructions simultaneously.	○	○	
7FF1H	Control data error	• Setting value is incorrect. • Setting value is out of range.	—	• Correct the setting value in the control data.	○	○	
7FF2H	Communication protocol setting error	• Instruction cannot be executed with the current communication protocol.	—	• Correct the setting value of the communication protocol.	○	○	
7FF5H	Transmission cancel at mode switching/ transmission sequence initialization	• Data transmission was cancelled by performing mode switching/reception data clearing during data transmission.	—	• Do not perform mode switching/reception data clearing during data transmission.	○	○	
7FF7H	Simultaneous access error	• Multiple external devices accessed a remote station on the same network at the same time.	—	• Multiple external devices must not access a remote station on the same network at the same time.	○		
F000H to FFFFH	—	Errors detected by the MELSECNET/H, MELSECNET/10 network system	—	• Take corrective action by referring to MELSECNET/H, MELSECNET/10 network system reference manual.	○		

10 - 20

10.2.2 A compatible 1C frame communications error code table

The following table lists the error code, error contents, and corrective action for errors generated during A compatible 1C frame communications.

Error code (Hexa-decimal)	Error	Error Contents	Corres-pondence signal name	Corrective action	Protocol		
					MC	Non Proce-dure	Bidire-ctional
00H	Disable during RUN	• A write command was designated when "Disable write during RUN" was set. • Parameter or sequence program was written during RUN.	C/N	• Change the setting to "Enable write during RUN" and restart data communications. • Stop the CPU and restart data communications.	○		
01H	Parity error	• The data does not match the parity bit setting.	P/S	• Match the Q series C24 and external device settings.	○		
02H	Sum check error	• The sum check calculated by the Q series C24 and the transmitted sum check are not the same.	P/S	• Check the external device sum check.	○		
03H	Protocol error	• Received message that is different from the control procedure with the communication protocol setting.	PRO	• Check and correct the external device transmit message and restart data communications.	○		
04H	Framing error	• The data does not match the stop bit setting.	SIO	• Match the Q series C24 and external device settings.	○		
05H	Overrun error	• The next data was received before the Q series C24 received all the preceding data.	SIO	• Decrease the transmission rate and restart data communications.	○		
06H	Character area error	• Designation method error in part of a message. • A command that does not exist was designated. • The number of processing points is outside the range for the command. • A device that does not exist was designated.	PRO	• Check and correct the external device transmit message and restart data transmission.	○		
07H	Character error	• Received data that cannot be used.	PRO		○		
08H	PLC access error	• The CPU cannot communicate with the Q series C24.	C/N	• Replace the CPU with a CPU that can communicate with the Q series C24.	○		
10H	PLC No. error	• The PLC No. is not "FF", or a station No. set in the network parameters.	C/N	• Check and correct the external device transmit message and restart data communications.	○		
11H	Mode error	• An error was detected upon access to the PLC CPU.	—	• Send again. • Conduct individual station recovery test and check the Q series C24.	○		
12H	Special function module designation error	• A special function module does not exist at the specified position.	C/N	• Check and correct the external device transmit message and restart data communications.	○		
21H	Special function module bus error	• An error was detected upon access to a special function module at the specified position.	C/N	• Check the error and take corrective action according to the manual of the corresponding module.	○		
42H	Other errors	✻ See POINT .			○		

POINT

- If an error occurs during A compatible 1C frame communications, the Q series C24 adds a 2-character error code (00H to 10H, 42H) to the "NAK" code and returns the "NAK" code to the external device and stores the error code (equivalent to QnA compatible 2C/3C/4C frame error code) to buffer memory address 25AH (CH1) or 26AH (CH2).
  The exact error contents can be checked by reading the value stored to the buffer memory.
  See Section 10.2.1 for a detailed description of the error codes.

10 - 21

10.2.3 Error code list while modem function is used

The following describes the error codes, contents and corrective actions for errors (including errors at the abnormal completion) that may occur while the Q series C24 modem function is used.
The error codes for the modem function are stored in the modem function error code storage area (address : 221H(545)) of the buffer memory.

* The reference pages listed in the table below are found in the User's Manual (Application).

Error code (Hexa-decimal)	Error	Error Contents	Corres-pondence signal name	Corrective action	Reference section
7FD0H	Modern function error	There is an error in the designation of the notification execution.	CHn ERR.	Set 0 to 1 to the notification execution designation.	Section 3.3.4
7FD1H		There is an error in the designation of the number of connection retries.		Set the number of connection retries in the range of 1 to 5.	
7FD2H		There is an error in the designation of the connection retry interval.		Set the connection retry interval in the range of 90 to 300 (s).	
7FD3H		There is an error in the initialization/connection time-out designation.		Set the initialization/connection time- out in the range of 1 to 60 (s).	
7FD4H		There is an error in the designation of the number of initialization retries.		Set the number of initialization retries in the range of 1 to 5.	
7FD5H		There is an error in the designation of the data number for initialization.		Designate the registered data number for initialization, or 0.	Section 3.3.4 Section 3.4.7
7FD6H		There is an error in the data for connection designated by the data number for connection.		Recheck the pager receiver designation.	Section 3.4.6
7FD7H				Recheck the dialing number of the external line.	
7FD8H				Recheck the telephone number designation.	
7FD9H		The line to the destination is being connected.		Connect the line or notify when the line to the destination is not connected.	Section 3.4.8 Section 3.4.9
7FDAH		There is an error in the designation of the data number for connection.		Designate a registered number for the data for connection.	Section 3.3.4 Section 3.4.8
7FDBH		There is an error in the designation of the GX Developer connection.		Set 0 to 1 to the GX Developer connection designation.	Section 3.3.4
7FDCH		There is an error in the data for connection designated by the data number for connection.		Recheck the waiting time for the notification-message part of the message transmission.	Section 3.4.6
7FDDH		A connection time-out error occurred.		• Recheck the telephone number in the data for connection. • Check if the destination is ready for a connection. • Recheck the set value of the connection time-out. • Recheck the initialization command.	Section 3.3.4 Section 3.4.5 Section 3.4.6
7FDEH		Connection to the modem/TA was unsuccessful, or the modem/TA is not connected.		• Check if there is any problem with the modem/TA by seeing the operation manual of the modem/TA. • Connect the modem/TA to the Q series C24. • Check the connection cable by seeing the operation manual of the modem/TA.	Section 3.2
7FDFH		Modem connection channel number is not designated.	—	Set 1 to 2 to the modem connection channel designation.	Section 3.3.4
7FE0H		Designated value of modem connection channel is incorrect.			

10 - 22

Error code (Hexa-decimal)	Error	Error Contents	Corres-pondence signal name	Corrective action	Reference section
7FE1H	Modern function error	There is an error in the designation of the user frame number.	CHn ERR.	• Recheck the user frame number. • Designate the registered user frame number. • Register the designated data for initialization.	Section 3.4.5 Section 3.4.6 Section 3.4.7
		There is an error in the designation of the output head pointer.		• Designate the output head pointer in the range of 1 to 100. • Designate the position (n-th position) where the data for initialization number is designated. • Designate the data for initialization number at the designated position (n-th position).	Section 3.4.7
7FE2H		There is an error in the designation of the output frame number.		Designate a registered data for initialization number within the range of the designated number of outputs from the location of the output head pointer.	Section 3.4.7
7FE3H		There is an error in the designation of the number of registered data bytes.		• Designate the data for initialization in the range of 1 to 78. • Designate 80 for the data for connection.	Section 3.4.5 Section 3.4.6
7FE4H		There is an error in the data for connection.		• Recheck the message length of the message for notification.	Section 3.4.6
7FE5H		There is an error in the designation of the no-communication interval time.		• Designate the no-communication interval time in the range of 0 to 120.	Section 3.3.4
7FE8H		The number of remote password mismatch exceeded the value designated at the address 200DH.		• Clear the storage area of the Accumulated count of unlock process abnormal completion (address: 22FCH) to 0.	

10 - 23

10.3 Troubleshooting by Symptom

This following shows troubleshooting of trouble generated during communications between the Q series C24 and external device according to the trouble symptom. When trouble occurs, first confirm the status of the Q series C24 and check the relevant item in the table below.

Symptom	Symptom description	Protocol			Reference section
		Dedicated	Non procedure	Bidirec-tional	
LED turns on/off (check according to Section 4.3)	• "RUN" LED turned off.	○	○	○	Section 10.3.1
	• "RD" does not blink even through an external device is transmitting a message.	○	○	○	Section 10.3.2
	• An external device transmitted a message and "RD" blinked, but the Q series C24 did not return a response message.	○			Section 10.3.3
	• An external device transmitted a message and "RD" blinked, but the Q series C24 did not turn ON the read request.		○	○	Section 10.3.4
	• ERR. LED turns on.	○	○	○	Section 10.3.20
Communication errors occurred (check according to Section 10.1.1)	• The "NAK" was turned ON.	○	○	○	Section 10.3.5
	• The "C/N" was turned ON.	○	○	○	Section 10.3.6
	• The "P/S" was turned ON.	○	○	○	Section 10.3.7
	• The "PRO" was turned ON.	○			Section 10.3.8
	• The "SIO" was turned ON.	○	○	○	Section 10.3.9
	• The "CH1. ERR. " or "CH2. ERR. " was turned ON.	○	○	○	Section 10.3.10
	• Communications are intermittently established and lost.	○	○	○	Section 10.3.11
	• Data that cannot be decoded was transmitted and received.	○	○	○	Section 10.3.12
	• Whether the cause of the communications error is in the Q series C24 or the external device is unknown.	○	○	○	Section 10.3.13
Cannot connect via modem	• Cannot communicate with GX Developer that supports the Q series C24.	○			Section 10.3.14
	• Cannot communicate with ISDN sub-address.	○			Section 10.3.15
The PLC CPU monitoring function does not operate in the designated cycle time.	• Does not operate in the cycle time designated in the constant cycle transmission setting.	○	○	○	Section 10.3.16
	• Does not operate in the cycle time designated in condition agreement transmission setting.	○	○	○	Section 10.3.17
Cannot receive by an interrupt program	• Cannot receive data.		○	○	Section 10.3.17
Cannot perform initial setting	• Cannot write setting value in flash ROM of the Q series C24.	○	○	○	Section 10.3.19

* If an error occurs while performing data exchange using the modem function described in User's Manual (Application) Chapter 3, first check the following items and confirm whether or not the error is caused by the modem/TA connection.
  If an error relating to the modem function is occurring, perform necessary corrective actions for each cause according to the reference sections given below:
  - Check the ON/OFF status of current I/O signals of the Q series C24.
  - Check the storage status for error codes related to the modem function. (See Sections 10.2.3.)
  - Check the ON/OFF status of the DR terminal of the modem/TA. (See the manual for the modem/TA.)

REMARK

The following are precautionary notes when exchanging data with an external device via one of the Q series C24 interfaces.

(1) When the power supply to the Q series C24 or external device is started, the remote device that is connected may generate a reception error.

(2) If the remote device that is connected starts up while data is being transmitted, the remote device side will generate a reception error.

(3) When the Q series C24 error LED lights up because a reception error has occurred, turn off the light if necessary in accordance with Section 10.1.
Also, if a reception error has occurred on the external device side, handle the error by seeing to the operating manual for the external device.

* Handle the occurrence of a reception error on the Q series C24 side using the following corrective actions.
  - When communicating with the MC protocol
    The Q series C24 will disregard the received data or returns a response message indicating an abnormal termination if it detects a reception error after receiving the head data of the command message in the set format.
    If the reception error is detected before the head data of the command message in the set format is received, the received data will be disregarded.
  - When communicating using non procedure protocol
    If the Q series C24 detects a reception error, the reception abnormal detection signal (X4, XB) turns ON.
    Perform procedures such as detection of reception error or clearing received data as required by following the explanations found in Sections 6.1.4 and 6.1.5.
  - When communicating using bidirectional protocol
    When the Q series C24 detects a reception error after the head data of a communication message for bidirectional protocol is received, it returns a response message indicating an abnormal termination.
    If the reception error is detected before the head data of the communication message for bidirectional protocol is received, the received data will be disregarded.

10.3.1 Troubleshooting when "RUN" LED is turned OFF

Symptom	Cause	Corrective action	MC	Bidirectional	Non procedure
• The Q series C24 "RUN" LED turned off.	• A transmission setting switch is set to an unusable position.	• Set the switch by GX Developer correctly and after writing to the CPU reset the CPU.	○	○	○
	• PLC CPU error.	• Remove the cause of the CPU error and reset the CPU. Note • During the Q series C24 and external device loopback test, the minimum parameters file must be written to the CPU beforehand.	○	○	○
	• Power module 5 V current capacity is insufficient.	• Calculate the 5 V current drain of each installed module. If the current capacity is insufficient, check power module selection. Note • Whether or not the current capacity is insufficient can be checked by disconnecting the expansion base and installing only the Q series C24 to the basic base.	○	○	○
	• Extraneous noise caused the Q series C24 to abnormal operation.	• Check if the shield wire is 2-point ground. • When ground is used with other devices, ground the Q series C24 independently.	○	○	○

10 - 26

10.3.2 Troubleshooting when "RD" LED does not blink even though an external device is transmitting a message

Symptom	Cause	Corrective action	MC	Bidirectional	Non procedure
• "RD" does not blink even through an external device is transmitting a message.	• Signal lines are not connected correctly.	• Check if the Q series C24 and external RD and SD signal lines are cross connected. • Use the external device OPEN statement to check if the opened port and the cable connection port are matched.	○	○	○
	• External device transmission control signals are not turned ON.	• Connect the wiring so that the "DSR", "CS", and other transmission control signals are ready. Note • Since the control signal specifications depend on the device, connect the wiring by seeing the instruction manual of the device used.	○	○	○
	• If the message passes through an RS-232 ↔ RS-422 converter, modem, etc., the signal is interrupted at one of the intervening devices.	• Check the specifications of the converter and modem and recheck the settings and wiring	○	○	○

10 - 27

10.3.3 Troubleshooting when the Q series C24 does not return a response message even though an external device transmitted a message and the "RD" LED blinked

Symptom	Cause	Corrective action	MC	Bidirectional	Non procedure
• An external device transmitted a message and "RD" blinked, but the Q series C24 did not return a response message. ("NEU" remains on and "SD" does not blink)	• Communication protocol is set incorrectly.	• Check if the communication protocol is set correctly. • Check if the mode was switched without using the buffer memory mode switching area. Note • The communication protocol setting contents and the communication protocol in the current operation can be checked at buffer memory addresses 250H to (CH1) and 260H (CH2).	○		
	• When "Check CD terminal" was set, the CD terminal was turned OFF.	• Since the message is initialized (skipped reading) when the CD terminal is turned OFF when "Check CD terminal" is set, change the wiring so that the CD terminal remains on all the time.	○		○
	• The header byte of the message is not data needed by the set protocol and format.	• Check if the external device sent a message matched to the protocol and format. Note • The Q series C24 skips all the messages transmitted until the header byte set for each protocol and format (for example, "ENQ (05H)" for format 1) is received.	○		○
	• The Q series C24 station No. switch setting and message station No. designation do not match.	• Check the Q series C24 station No. setting and message station No. designation. Note • When the station No. designation is local station after the header byte set for each protocol and format is received, the Q series C24 performs receive processing.	○		
	• The Q series C24 data communications monitoring time is set to "infinite", or the monitoring time is too long.	• Set, or shorten, the monitoring time and retransmit the message from the external device and determine the trouble from the contents of the time-out error. Note • Error detection by watchdog timers (timer 0 to timer 2) is possible in the following cases. • When part of a message is skipped. • When transmission from an external device is interrupted. • When a link error was generated while accessing another station over a MELSECNET/H, MELSECNET/10. See Chapter 6 of User's Manual (Application) for a detailed description of the monitoring time.	○		○
	• The path setting of the PLC CPU to be accessed is incorrect.	Check the path of the PLC CPU to be accessed and set the path again.	○		

10.3.4 Troubleshooting when an external device transmitted a message and "RD" LED blinked, but the Read Request signal was not turned ON

Symptom	Cause	Corrective action	MC	Bidirectiona	Non procedure
• An external device transmitted a message and "RD" blinked, but the read request signal (X0) was not turned ON.	• Communication protocol is set incorrect.	• Check if the communication protocol is set correctly. • Check if the mode was switched without using the buffer memory mode switching area. Note • The communication protocol setting contents and the communication protocol in the current operation can be checked at buffer memory addresses 250H to (CH1) and 260H (CH2).		○	○
	• When "Check CD terminal" was set, the CD terminal was turned off.	• Since messages are skipped when the CD terminal is turned OFF when "Check CD terminal" is set, change the wiring so that the CD terminal remains on all the time.		○	○
	• When DC control is selected, the necessary DC codes are not transmitted.	• Check if a message is transmitted without transmitting "DC1 (11H)" after the external device transmits "DC3 (13H)" during DC1/DC3 external control. • Check if the next message is transmitted without adding "DC2 (12H)" after the external device transmits "DC4 (14H)" during DC2/DC4 external control.		○	○
	• The end code was not received, or fixed length data was not received.	• Check if the end code set at the Q series C24 and the end code transmitted from the external device are the same. • Check if the external device transmitted the fixed length designated at the Q series C24. • Check if the trailer frame was transmitted during communications by user frame. Note • When the send data from the external device is correct, take the corrective action described in Sections 10.3.10 and 10.3.11.		○	○
	• The Q series C24 setting and message format do not match.	• The data count basics, message format, etc. depend on the following settings. · ASCII-BIN conversion enable/disable · Transparent code setting · User frame setting See the relevant section for a description of operation according to the set contents and setting of each item.		○	○
	• The Q series C24 data communications monitoring time is set to "infinite", or the monitoring time is too long.	• Set, or shorten, the monitoring time and retransmit the message from the external device and determine the trouble from the contents of the time-out error. Note • Error detection by the watchdog timer (timer 0 to timer 2) is possible in the following cases. · When part of a message is skipped. · When transmission from an external device is interrupted. See Chapter 6 of User's Manual (Application) for a detailed description of the monitoring time.		○	○

10 - 29

10.3.5 Troubleshooting when communication error "NAK" generates

<table>
<tr><th>Symptom</th><th>Cause</th><th>Corrective action</th><th>MC</th><th>Bidirectional</th><th>Non procedure</th></tr>
<tr><td rowspan="2">• Communication error signal "NAK" turned on.</td><td>• See section that describes the communication error signal ("C/N", "P/S", "PRO", "SIO") that are turned on simultaneously when the "NAK" signal is turned on.</td><td>• Take corrective action corresponding to the contents of the error.</td><td>○</td><td></td><td></td></tr>
<tr><td colspan="5">Note
Since the error code is added to "NAK" and is transmitted from the Q series C24 to the external device when the "NAK" signal is turned on, take the corrective action described in the error code table (see Section 10.2).
Since the error code added when "NAK" is transmitted is stored to the Q series C24 buffer memory shown below, it can also be checked at the Q series C24.
<table>
<tr><th colspan="2">Error code storage buffer memory address</th></tr>
<tr><td>CH1 side</td><td>25AH</td></tr>
<tr><td>CH2 side</td><td>26AH</td></tr>
</table></td></tr>
</table>

10.3.6 Troubleshooting when communication error "C/N" generates

<table>
<tr><th>Symptom</th><th>Cause</th><th>Corrective action</th><th>MC</th><th>Bidirectional</th><th>Non procedure</th></tr>
<tr><td rowspan="3">• Communication error signal "C/N" turned on.</td><td>• The Q series C24 cannot be installed in the CPU.</td><td>• Change to a CPU to which the Q series C24 can be installed.</td><td>○</td><td>○</td><td>○</td></tr>
<tr><td>• PLC No. designated local station (FF), or a station other than a station No. set with the network parameters.</td><td>• Change the PLC No. to local station (FF), or a station No. set with the network parameter and restart data communications.</td><td>○</td><td></td><td></td></tr>
<tr><td>• Routing parameters between CPU with the Q series C24 loaded and communications destination CPU are not set.</td><td>• Check the routing parameters and set them up to the communications destination CPU.</td><td>○</td><td></td><td></td></tr>
</table>

Symptom	Cause	Corrective action	MC	Bidirectional	Non procedure
• Communication error signal "C/N" turned on.	• An error was generated on the MELSECNET/ H, MELSECNET/10.	• Check the error contents from the state of SB and SW related to the MELSECNET/H, MELSECNET/10 with the GX Developer monitor, etc. and perform the checks and take the corrective action described in the MELSECNET/H, MELSECNET/10 reference manual.	○		
	• The local station CPU on the MELSECNET/H, MELSECNET/10 generated an error.				
	• Module installation address designation during communications with intelligent function module is incorrect.	• Change the transmit message designation data.	○	○	○
	• A command that cannot be transmitted during RUN (sequence program, parameters, etc.) was transmitted, or "Disable write during RUN" is set.	• Stop the CPU and restart data communications.	○		
		• Set the "Enable/disable write during RUN" switch to "Enable" by command.	○		

10.3.7 Troubleshooting when communication error "P/S" generates

Symptom	Cause	Corrective action	MC	Bidirectional	Non procedure
• Communication error signal "P/S" turned on.	• Data does not match the parity bit setting.	• Check the Q series C24 and external device data format and match the settings.	○	○	○
	• Sum check codes do not match.	• Check if the sum check code transmitted from the external device is correct. (Recalculate)	○		
	• When CH1 and CH2 are used in the linked mode, the cable is not connected to one of the interface.	• When using CH1 and CH2 independently, check that the Q series C24 is not in the linked mode. • When using CH1 and CH2 in the linked mode, also connect the cable to both of the interfaces. Note • If the cable is not connected to one of the interfaces when CH1 and CH2 are used in the linked mode, noise may enter and the data may be destroyed and "Data cannot be decoded" or "Communications error cause" may occur.	○	○	○

10.3.8 Troubleshooting when communication error "PRO." generates

Symptom	Cause	Corrective action	MC	Bidirectional	Non procedure
• Communication error signal "PRO" turned on.	• Communications were performed with a control procedure different from the Q series C24 communication protocol setting. • Some of the data are different from the control procedure. • Designated command does not exist. • The device No. designation is not the character count corresponding to the command.	• Check the Q series C24 communication protocol setting and the message from the external device and match the settings, or correct the message and restart data communications.	○		
	• The characters in the message include a data other than the "A to Z", "0 to 9", "␣", and control data.	• Check and correct the external device message and restart data communications. Note • Only the data "0 to 9" and "A to F" can be handled as character area data during communications using an MC protocol (ASCII mode). Therefore, when transmitting a character string as data, convert the ASCII code of each character string to 2-byte binary code. Examples) • Transmitting the character "G" The ASCII code for the character "G" is 47H and is transmitted as the two bytes 34H, 37H. • Transmitting the character "A" The ASCII code for "A" is 41H and is transmitted as the two bytes 34H, 31H. If the ASCII code 41H for the character "A" is transmitted unchanged, the Q series C24 ASCII-BIN conversion will convert it to AH (10) and pass it to the PLC CPU.	○		
	• A device No. outside the designated range was designated.	• When designating a device, check "Device setting" of the parameters written to the CPU and correct it to a device No. within the designated range and restart data communications.	○		
	• A remote RUN/STOP request was issued while remote STOP was applied from another module.	• Check if remote STOP is applied from another module and restart data communications.	○		

10 - 32

10.3.9 Troubleshooting when communication error "SIO" generates

Symptom	Cause	Corrective action	MC	Bidirectional	Non procedure
• Communication error signal "SIO" turned on.	• Data does not match the stop bit setting.	• Check if the Q series C24 and external device settings are the same.	○	○	○
	• Transmission rate is too fast and the next data is transmitted before the Q series C24 completes processing of the receive data.	• Decrease the transmission rate and restart data communications.	○	○	○
	• Data larger than the receive buffer size was received.	• Use DTR and DC control and interrupt transmission before the buffer becomes full. Perform RS and CS control when the modem function is used. • Increase the transmission interval and provide an ample PLC CPU read processing time. Note • The non procedure protocol stores the data received up to first the end code received, or fixed length data, to the non procedure receive buffer memory and turns on the Read Request signal to the PLC CPU. If the next data is sent while the Read Request signal is ON, the data is temporarily stored to the OS receive buffer. When the OS receive buffer becomes full, the Q series C24 skips the rest of the data and turns on the "SIO" LED.		○	○
	• With a multidrop link, two or more devices transmitted data at the same time.	• Connect the external devices and the Q series C24 in a 1:1 configuration and perform a communications test. Since data is transmitted simultaneously from two or more devices with a multidrop link when normal communications among all the devices is possible, interlock the devices so that cannot transmit simultaneously.	○	○	○

10 - 33

10.3.10 Troubleshooting when communication error "CH1 ERR.", "CH2 ERR." generate

<table>
<tr><th>Symptom</th><th>Cause</th><th>Corrective action</th><th>Dedicated</th><th>Bidirectional</th><th>Non procedure</th></tr>
<tr><td rowspan="6">• "ERR." LED turned on.</td><td>• There is an error in the communication protocol or transmission setting.</td><td>• Read the error code from the buffer memory and check the error contents and change the switch setting to the correct setting.</td><td>○</td><td>○</td><td>○</td></tr>

10.3.11 Troubleshooting when communications is intermittently established and lost

Symptom	Cause	Corrective action	MC	Bidirectional	Non procedure
• Communications are intermittently established and lost. (*1)	• With a multidrop link, two or more devices transmitted data at the same time.	• Connect the external devices and the Q series C24 in a 1:1 configuration and perform a communications test. Since data is transmitted simultaneously from two or more devices with a multidrop link when normal communications among all the devices is possible, interlock the external devices so that they do not transmit simultaneously.	○	○	○
	• The signal cable wiring connection is faulty.	• Replace the cable, or make the connections firm.	○	○	○
	• When "Check CD terminal" is set, the CD signal is turned on/off repeatedly.	• Change the wiring so that the CD signal remains ON all the time, or change the setting to "Do not check CD terminal".	○	○	○
	• When half-duplex communications is selected, the ON/OFF timing of each signal is not matched.	• Control the external device so that the ON/OFF timing of each signal is matched. See Chapter 8 of User's Manual (Application).		○	○
	• Requested processing of the next transmission before the processing of the current transmission is completed. • Requested processing of the next reception before the processing of the current reception is completed.	• Make sure to obtain handshake in the sequence program.	○	○	○

*1 The following explains how to take corrective actions when a normal exit response message cannot be received upon sending of a command message.

1) When a response message of abnormal end is received
When an external device sent a command message and received an abnormal end response message, take corrective action with the error according to the error code in the response message (see Section 10.2).

2) When response messages cannot be received
Change the setting value for the response monitoring time (timer 1, default value is 5 seconds).
(See Section 6.2 of the User's Manual (Application).)
If response messages still cannot be received after changing the setting value, check the communication protocol setting of the corresponding interface, the ON status of the displayed LED, and the connection cable.

3) When the first part of a response message cannot be received
Increase the setting value of the message wait time (the default value is 0 ms).
(See Section 6.4 of the User's Manual (Application).)
If response messages still cannot be received after increasing the setting value, it is necessary to reduce the processing time from the end of transmission processing to the start of reception processing on the external device side.

10 - 35

10.3.12 Troubleshooting when data that cannot be decoded is transmitted and received

Symptom	Cause	Corrective action	MC	Bidirectional	Non procedure
• Data that cannot be decoded was transmitted and received	• With a multidrop link, two or more devices transmitted data at the same time.	• Connect the external devices and the Q series C24 in a 1:1 configuration and perform a communications test. Since data is transmitted simultaneously from two or more devices with a multidrop link when normal data communications among all the devices is possible, interlock the external devices so that they do not transmit simultaneously.	○	○	○
	• Data does not match the parity bit setting.	• Match the Q series C24 and external device parity bit settings. Note • If the setting of one side is data bit length 7 bits and with parity and the setting of the other side is data length 8 bits and without parity, the number of transmission/receive bits will be the same and the data will sent and receive without generating an error.	○	○	○
	• Data does not match the parity bit setting.		○	○	○
	• Transmission rate settings do not match.	• Match the Q series C24 and external device transmission rates.	○	○	○
	• With a multidrop link, the terminal resistor is not connected correctly.	• Check if the terminal resistor (110Ω or 330Ω in case of the Q series C24) is connected to the stations at both ends of the link.	○	○	○
	• When CH1 and CH2 are used to the linked mode, there is an interface without cable connection.	• When using CH1 and CH2 independently, check that the Q series C24 is not in the linked mode. • When using CH1 and CH2 in the linked mode, also connect the cable to both of the interfaces. Note • If the cable is not connected to one of the interfaces when CH1 and CH2 are used in the linked mode, noise may enter and destroy the data and "Data cannot be decoded" or "Communication error cause" may occur.	○	○	○

10 - 36

10.3.13 Troubleshooting when it is unclear whether the communication error cause is in the Q series C24 or an external device

Symptom	Cause	Corrective action	Dedicated	Bidirectional	Non procedure
• Whether the communications error cause is in the Q series C24 or an external device is unclear.	—	• Test the Q series C24 as described below to check where the cause is. 1) Check the hardware. • The Q series C24 must be installed firmly. • The pins of the Q series C24 must not be bent or otherwise abnormal. 2) Test the Q series C24 alone. (See Section 4.7.) • ROM/RAM/switch test must not generate any errors. • Self loopback test must not generate any errors. 3) Check the state of the PLC CPU. • There must not be any errors that stop PLC CPU operation. Note • The following methods are available for testing if normal communications are possible with the Q series C24 alone. 1) With one the Q series C24, set CH1 and CH2 to the non procedure protocol and connect the wiring the same as for the self loopback test and transmit data from one channel and receive the transmitted data at the other channel. If the transmitted data and the received data are the same, transmit and receive processing is performed normally. 2) When two Q series C24 are available, set one Q series C24 to the non procedure protocol and the other Q series C24 to a dedicated protocol and transmit an MC protocol message from the non procedure protocol station. If the MC protocol station returns the transmit message normally, transmit and receive processing is normal.	○	○	○

10.3.14 Troubleshooting when data cannot be communicated with the GX Developer that supports serial communication modules

Circumstance	Cause	Corrective action	MC	Non procedure protocol	Bidirectional protocol
• Data cannot be communicated with GX Developer supporting the Q series C24.	• Communication protocol setting is incorrect.	• Set the communication protocol to MC protocol, format 5.	○	○	○
	• Transmission setting does not match the external device.	• Review the transmission setting.	○	○	○
	• Communication rate does not match the external device.	• Review the communication rate setting.	○	○	○

10.3.15 Troubleshooting when data cannot be communicated with the ISDN sub-address

Circumstance	Cause	Corrective action	MC	Non procedure protocol	Bidirectional protocol
• Data cannot be communicated with ISDN sub-address	• Sub-address is incorrect.	• Review the sub-address.	○	○	
	• Modem does not support ISDN sub-address.	• Use modem that supports ISDN sub-address.	○	○	
	• Sub-address is incorrectly partitioned.	• Review how to partition the sub-address using the TA manual.	○	○	

10.3.16 Troubleshooting when constant cycle transmission does not operate normally

Circumstance	Cause	Corrective action	MC	Non procedure protocol	Bidirectional protocol
• Does not operate in the cycle time designated in the constant cycle transmission setting	• The setting value of the constant cycle transmission is incorrect.	• Review the constant cycle transmission setting.	○	○	
	• The cycle time is affected by some causes.	• Remove the causes or designate the cycle time anticipating the causes.	○	○	

10.3.17 Troubleshooting when condition agreement transmission does not operate normally

Circumstance	Cause	Corrective action	MC	Non procedure protocol	Bidirectional protocol
• Does not operate in the cycle time designated in condition agreement transmission setting	• The setting value of the condition agreement transmission is incorrect.	• Review the condition agreement transmission setting.	○	○	
	• The cycle time is affected by some causes.	• Remove the causes or designate the cycle time anticipating the causes.	○	○	

10.3.18 Troubleshooting when data cannot be received by an interrupt program

Circumstance	Cause	Corrective action	MC	Non procedure protocol	Bidirectional protocol
• Cannot receive data with the interrupt program	• Interrupt issuance was not designated.	• Designate interrupt issuance.		○	○
	• Receiving by instruction other than BUFRCVS.	• Use BUFRCVS instruction to receive interrupt data.		○	○
	• "Parameter setting" - "PC system setting" - or "Interrupt pointer setting" are not set on the PLC CPU side, or the settings are incorrect.	• Review "Parameter setting" - "PS system setting" - "Interrupt pointer setting" on the PLC CPU side		○	○

10.3.19 Troubleshooting when data cannot be written to Flash ROM

Circumstance	Cause	Corrective action	MC	Non procedure protocol	Bidirectional protocol
• Cannot write data to Flash ROM	• Flash ROM overwrite allow/prohibit was not set to allow.	• Set Flash ROM overwrite allow/prohibit to allow.	○	○	○
	• Setting change was not set to allow in the switch settings by GX Developer.	• Set setting change to allow in the switch setting by GX Developer.	○	○	○

10.3.20 Troubleshooting when the "ERR" LED is lit

Circumstance	Cause	Corrective action	MC	Non procedure protocol	Bidirectional protocol
• "ERR" LED is lit	• A communication error has occurred.	• Check the error and remove the cause according to Section 10.1.1.	○	○	○
	• Switch settings of the Q series C24 are incorrect.	• Review the switch settings of the Q series C24.	○	○	○

APPENDIX

Appendix 1 Functional Improvements of the Q Series C24

The Q series C24 of function version B has several functions that have been added or changed from the conventional product (function version A).
This chapter explains a comparison of the functions of Q series C24/QSCU accompanied by the change/addition of functions, and explains how to utilize programs created for function version A as well as how to incorporate function version B modules into the existing system.

Appendix 1.1 Comparison of the Functions of Q Series C24/QSCU

(1) Comparison of the functions of Q series C24

The following table lists the functions added and changed for function version B.

Function				○ : Function added/ Changed
Communication using the MC protocol				
	Communication with ASCII code	Communication with QnA compatible 2C/3C/4C frame	Formats 1 to 4 exist for each.	
		Communication with A compatible 1C frame		
	Communication with binary code	Communication with QnA compatible 4C frame	Format 5	
	Read/write of device memory	Batch read/write in bit/word units		
		Monitoring of device memory		
		Batch read/write of multiple blocks		
		Read/write by extension designation		
		Accessing other stations via network system		
	Reading/writing from/to the buffer memory of the Q series C24			
	Reading/writing from/to the buffer memory of intelligent function modules			
	Reading/writing from/to sequence program files			
	Monitoring the PLC CPUs (PLC CPU monitoring function)			
		Transmission of the monitoring information using the modem function.		○
	Status control of the PLC CPUs (remote RUN/STOP, etc.)			
	Turning on/off input signals of the Q series C24 from an external device (global function)			
	Data transmission from a PLC CPU to an external device (on-demand function)			
Communication using non-procedure protocol				
	Data transmission/reception in any format			
	Data transmission/reception using user frames			
	Data reception using format-0 (* 1)			
	Data reception using format-1			○
	Data reception by interrupt programs			
	Monitoring the PLC CPUs (PLC CPU monitoring function)			
		Transmission of the monitoring information using the modem function.		○
	ASCII data transmission/reception by ASCII-BIN conversion			
	Data transmission/reception by specifying transparent code			
		Specification of Receive transparent code		
		Specification of Transmission transparent 1st (* 2)		
		Multiple specification of Transmission transparent 2nd to 10th		○
	Reception data clear by dedicated instruction (CSET instruction)			○

App. - 1

App.

Function				○ : Function added/ Changed
Communication using bidirectional protocol				
	Data transmission/reception in any format			
	Data reception by interrupt programs			
	ASCII data transmission/reception by ASCII-BIN conversion			
	Data transmission/reception by specifying transparent code			
		Specification of Receive transparent code		
		Specification of Transmission transparent 1st (＊2)		
		Multiple specification of Transmission transparent 2nd to 10th		○
Registration of user frame for data communication				
	Registration of changeable data (horizontal parity code and sum check code of two's-complement number are added)			○
Communication via public network, etc. (modem function)				
	Remote password check			○
Transmission control		DC code control (including Xon/Xoff control)		
		DTR/DSR (ER/DR) control		
Communication protocol switching				
Independent/linked operation of each interface				
Monitoring/testing of initial settings and setting values with utility package				
	Startup from the system monitor (＊3)			
	Addition to the setting items			○ (See (2))
GX Developer and GOT connection				○
	Simultaneous connection of GX Developer and GOT to the Q series C24 (＊4)			○
Support for multiple PLC system				○
	Communication with non-control CPU using the MC protocol			
		Communication with QnA compatible 4C frame (ASCII code)	Formats 1 to 4	○
		Communication with QnA compatible 4C frame (binary code)	Format 5	○
	Multiple PLC setting using GX Developer (I/O assignment, switch setting, interrupt pointer setting, etc.)			○
Data transmission/reception at low speed (transmission speed: 50 bps)				○

＊1 The data reception using format-0 refers to the method of receiving data by user frame, which was supported in the Q series C24 of function version A.

＊2 The Q series C24 of function version A is capable of setting one pair of transparent code and additional code per interface for both transmission and reception.

＊3 This function is available in GX Developer (SW6D5C-GPPW-E).

＊4 GX Developer can only be connected to the CH1 side in case of the Q series C24 of function version A.
It is not possible to connect both GX Developer and the GOT to the two interfaces at the same time.

App. - 2

(2) List of added setting items for QSCU

The following table lists the setting items added to QSCU to conform to the specification of the Q series C24 of function version B.

Screen (System setting/monitor)	Additional setting item	Software version			Reference section
		D, C	B	A	
Modem function system setting	Circuit disconnect wait time (PLC CPU watch use)	○	×	×	Section 8.4.4 Section 8.6.2
	Remote password mismatch notification count designation				
	Remote password mismatch notification accumulated count designation				
Modem function monitor/test	Accumulated count of unlock process normal completion				
	Accumulated count of unlock process abnormal completion				
	Accumulated count of lock process based on circuit disconnect				
Transmission control and others system settings Transmission control and others monitor	Transmission transparent code designation (2nd to 10th)				Section 8.4.5 Section 8.6.3
Non procedure system setting Non procedure monitor/test	User frame receive format designation (1st to 4th)				Section 8.4.7 Section 8.6.5
	Exclusive format-1 received data count (1st to 4th)				
Auto refresh setting	Accumulated count of unlock process normal completion				Section 4.6
	Accumulated count of unlock process normal completion				
	Accumulated count of lock process based on circuit disconnect				

○ : Setting possible × : Setting impossible

POINT

(1) QSCU software of version C or later supports the Q series C24 of function version B.

(2) See Section 2.6 of this manual for how to check the software version of QSCU.

App. - 3

Appendix 1.2 Precautions when Updating the Module from Function Version A to B

This section explains how to utilize programs created for the Q series C24 of function version A for the Q series C24 of function version B and how to incorporate function version B into the existing system.

(1) Program utilization

Programs created for the Q series C24 of function version A can be used as they are for the Q series C24 of function version B.

(2) Incorporation into the existing system

The wiring used for function version A can be used as is for the Q series C24 of function version B.

App. - 4

Appendix 2 QnA/A Series Module

This section explains a comparison of the functions of the Q series C24 and QnA/A series modules, and explains how to utilize programs created for A series modules as well as how to install the Q series C24 into the existing system.
QnA/A modules refer to the following products.

Model name	Product name
QC24N	AJ71QC24N (-R2,R4), A1SJ71QC24N (-R2)
QC24	AJ71QC24 (-R2,R4), A1SJ71QC24 (-R2)
UC24, C24-S8	AJ71UC24, A1SJ71UC24 (-R2,R4,PRF), AJ71C24-S8

Appendix 2.1 Functional Comparison with the Q series C24 and the QnA/A Series Modules

The following shows a functional comparison between the Q series C24 and the QnA/A series modules.
The ○ symbol in the model name columns indicates that the corresponding functions are compatible between the applicable models (for more information, see the manual for each module).
Indicates functions that have been added to or modified from the QnA/A series modules.

Function			Q series C24	QC24N	QC24	UC24	C24-S8
Communication using MC protocol			—				
	Communication in QnA compatible 3C frame	Communication with ASCII code	○	○		×	×
	Communication in QnA compatible 4C frame		○	○			
	Communication in QnA compatible 2C frame		○	○	×	×	×
	Communication in A compatible 1C frame		○	○			
	Communication in QnA compatible 4C frame	Communication with binary code	○	○		×	×
	Read/write of QCPU device memory		—				
	Batch read/write of device memory (＊5) ＊ Excluding multiple block batch read/write.		○	○		○ (＊1)	○ (＊1)
	Multiple block batch read/write (＊5)		○ (＊2)	○ (＊2)	×	×	×
	Accessing other stations (via network/data link)		○ (＊3)	○		○	○
	Transmission from the PLC CPU (on-demand)	Arbitrary data	○	○		○	○
		Using user frame	○	○		×	×
	Communication with m:n connection between the PLC CPU and external devices		○	○			
Communication using non procedure protocol			—				
	Transmission/receive with arbitrary format		○	○			
	Transmission/receive with user frame		○	○		○ (＊4)	×
	Transmission/receive with ASCII-BIN conversion		○	○		×	×
	Transmission/receive with transparent code designation		○	○		×	×
Communication using bidirectional protocol			—				
	Transmission/receive with arbitrary format		○	○			
	Transmission/receive with ASCII-BIN conversion		○	○		×	×
	Transmission/receive with transparent code designation		○	○		×	×

Function		Q series C24	QC24N	QC24	UC24	C24-S8
Accessing other stations with link dedicated instructions		×	○ (via QC24 (N))		×	×
Interrupt processing (at data reception)	Non procedure protocol	○	×	×	×	×
	Bidirectional protocol					
Communication via public lines using modem function		○	○	×	×	×
Communication using the PLC CPU monitoring function		○	×		×	×
Auto refresh directed to the PLC CPU		○	×		×	×
Transmission control	DC code control	○	○			
	DTR/DSR signal control	○	○			
Half-duplex communication control		○	○			
Mode switching		○	○			
Independent operation of two interfaces	Setting the same protocol	○	○		×	
	Setting different protocols	○	○			
Linked operation of two interfaces		○	○		○	
Registering initial setting values of the buffer memory		○ (Flash ROM)	○ (EEPROM)		×	×
Registering user frame					×	×
Connection forms with external devices	1:1, 1:n	○	○			
	m:n	○	○			
I/O signal transmission/receive by multi drop link function		×	×		○	×
Connection of GX Developer		○	○			
Registering and monitoring of setting values by the utility package		○	×		×	×
PLC that can be mounted		QCPU MELSECNET/H remote I/O station	QnACPU MELSECNET/10, Remote I/O station		ACPU AnACPU AnUCPU QnACPU	ACPU AnACPU AnUCPU QnACPU
Data transmission rate (bps)		115200 maximum	115200 maximum	19200 maximum	19200 maximum	19200 maximum

○: Function exists/possible ×: No function/impossible

*1 Access is possible only within the range of an AnACPU device.

*2 A multiple block batch read/write function can be used for the local station QCPU to which the Q series C24 is mounted and the next CPU module, which will be another station, via MELSECNET/H, MELSECNET/10.

Function	PLC CPU			
	QCPU	QnACPU	Q2AS(H)	Q4AR
Multiple block batch read/write	(All allowed)	(9707B or later products) *		(All allowed)

* This function is added to modules showing 9707B or later in the package indication and the DATE column of the rating plate.

*3 Access to other stations cannot be performed via data link system (MELSECNET(II), MELSECNET/B).

*4 Transmission is only possible using the printer function.

*5 When the Q series C24 is used, it is possible to read/write a maximum of 960 words (in case of QC24(N), it is possible to read/write a maximum of 480 words.)

Appendix 2.2 Using Programs Designed for the QC24 (N) and Installing the Q Series C24 into Existing Systems

This section explains how to use programs designed for serial communication modules in the QnA series and the installation of the Q series C24 into an existing system.

POINT

When using the Q series C24, make sure to set the operation mode, station number, and transmission specifications with the following parameter setting screen of GX Developer.

- "Intelligent function module switch setting" screen

The Q series C24 does not have the setting switches to set the operation mode, station number, and transmission specification that are available in the serial communication modules for QnA series.

Appendix 2.2.1 Using programs designed for the QC24 (N)

The data communication between the QnACPU and external devices as well as other QnACPU which has been performed by QC24(N) can also be performed by the Q series C24.
The following explains how to use programs designed for QC24(N) during data communication using the Q series C24.

(1) The communication programs directed to the QC24(N) on the external device side and the communication programs on the QnACPU (self-station) side to which the QC24(N) is mounted can be used for the Q series C24.
However, note the following points.
- There is no function that allows data communication with other station's PLC CPUs by a data link instruction.
Delete the part of data communication program by data link instructions.
- When using a new function, create a new program.

(2) Make sure to check operation when using communication programs for QC24(N) on the external device side and the QnACPU (self-station) side.

(3) The notes during data communication by RS-422/485 interface also apply to the Q series C24.
- Take measures against data error reception on the external device side (see Section 3.3.3).
- Operation of RS-422/485 interface on the PLC side.

Appendix 2.2.2 Installing on existing systems

The following explains the Installation of the Q series C24 on an existing system.

(1) Installing on a multidrop connection system

The Q series C24 can be installed on an existing system to which the PLC CPU and external devices are connected as 1:n or m:n multidrop connection (*1).

*1 This is when a QC24(N) or a computer link module (such as AJ71UC24) is used as the PLC CPU module of the multidrop connection.

However, there are frame restrictions when data communication is performed. (See the Reference Manual.)

(2) Replacing the QnACPU module with a QCPU

The wiring used by the QC24(N) can be used as is.

POINT
The functional use is the same, except for the functions added by the Q series C24 to the conventional module. However, with the introduction of high-speed QCPUs, there may be cases in which communication cannot be performed normally when a PLC module in the QnA series is replaced by a Q series PLC. When a module is changed to a Q series PLC module, make sure to perform an operation check.

Appendix 2.3 Using Programs Designed for the Computer Link Module and Installing the Q Series C24 into Existing Systems

This section describes how to use programs created for A series computer link modules and installing the Q series C24 into an existing system.

POINT
When using the Q series C24, make sure to set the operation mode, station number, and transmission specifications with the following parameter setting screen of GX Developer. • "Intelligent function module switch setting" screen The Q series C24 does not have the setting switches to set the operation mode, station number, and transmission specification that are available in the computer link module for A series.

Appendix 2.3.1 Using programs designed for the computer link module

The data communication between the PLC CPU and external device as well as other PLC CPU that has been performed by A series computer link modules (hereinafter abbreviated as UC24/C24-S8) can also be performed using the Q series C24. However, UC24/C24-S8 and the Q series C24 have major differences in the following points.
For PLC CPU side, create a new program according to the explanation in the section of the function used.
(Differences between UC24/C24-S8 and the Q series C24)

- Initial setting items and the setting method of addresses and special application areas of the buffer memory
- Input/output signals for handshake
- Dedicated instructions of the PLC CPU

(1) Initial settings for special application area in buffer memory

1) In the Q series C24 the addresses for special application areas in the buffer memory are different from those of UC24/C24-S8. The Q series C24 has more initial setting items.
   The setting method is different such that the settings are performed using the utility package (QSCU).
2) Register necessary initial setting values according to Chapter 8.
3) The default value for the CD terminal check setting is changed to "No check".

(2) Data communication using the MC protocol (identical to the communication functions of the dedicated protocol of UC24/C24-S8)

(a) Communication protocol setting
   Data communication is performed using an A compatible 1C frame by setting the communication protocol setting of the Q series C24 specified by GX Developer to the same form as set in the mode setting switch of UC24/C24-S8.

(b) Command message and response message

1) The message format used in the data communication using the A compatible 1C frame is the same as the message format of UC24/C24-S8.
2) Check available commands and devices that can be accessed in Chapter 8 of the Reference Manual, and access the PLC CPU from the external device.
3) For the QCPU, only read/write of device memory is possible.
For the range of devices that can be accessed, see Section 5.2.1 of the Reference Manual.
* The devices added to the QCPU, i.e. the latch relay (L), step relay (S), and file register (R) devices, are accessed using commands for QnA compatible 2C/3C/4C frames. It is necessary to create new programs.

(c) Accessing other stations

1) When accessing other station's PLC CPU via the MELSECNET/10, "Valid module during other station access" must be designated in the parameter setting by GX Developer.
2) Check the stations that can be accessed in Chapter 5 of the Reference Manual, and access the PLC CPU from the external device.
3) When it is necessary to access other stations on other MELSECNET/10, data communication must be performed in a QnA compatible 3C/4C frame.
Create a new program for the external device side according to Chapter 3 of the Reference Manual.
4) It is not possible to access other stations via the MELSECNET(II)/B.

(d) Transmitting data to the external device by the on-demand function

1) The program for data transmission on the PLC CPU side is different from when UC24/C24-S8 is used.
Create a new program on the PLC CPU side according to Section 3.11 in the Reference Manual.
2) Data to be sent to the external device is identical to when the UC24/C24-S8 is used.

(3) Data communication using the non procedure protocol

(a) Data transmission/reception

1) The same data transmission/reception as used by UC24/C24-S8 can be performed.
2) Create a new program for data communication upon checking functions and instructions used on the PLC CPU side in Chapter 6 of this manual and Chapter 11 of the User's Manual (Application).
Data transmission/reception is performed using dedicated instructions.

3) When data is received by a reception end code, the external device side must send the end code data (the default is CR+LF (code: 0D$_H$ and 0A$_H$) at the end of the data sent to the PLC CPU side.
Once any end code is registered, data can be transmitted in the same way as for the UC24/C24-S8.
4) The external device side can receive data from the Q series C24 in the same ways as UC24.

(b) Message transmission by printer function (when using programs designed for UC24)

1) Message transmission using the printer function of the UC24 can be implemented by the data transmission function that uses a user frame.
2) For the PLC CPU, register and send messages according to the User's Manual (Application).
Messages handled by the UC24 will become user frames in the Q series C24.

(4) Data communication using the bidirectional protocol

(a) Setting to add a sum check code to a message
The setting to add a sum check code to a message has been changed. It is set during switch setting operation by GX Developer.

(b) Data transmission/reception

1) The same data transmission/reception as used by UC24/C24-S8 can be performed.
2) Create a new program for data communication upon checking functions and instructions used on the PLC CPU side in Chapter 7.
Data transmission/reception is performed using dedicated instructions.
3) The external device can transmission/receive data in the same way as the UC24/C24-S8.

(5) Others

1) The Q series C24 has other functions that are equivalent to those of UC24/C24-S8, which are not mentioned above.
2) Check functions and specifications in this manual and the manuals listed below, and use the applicable functions.
- User's Manual (Application)
- Reference Manual

Appendix 2.3.2 Installing the Q series C24 into existing systems

This section shows the notes when installing the Q series C24 into an existing system that uses UC24/C24-S8.

(1) Data communication using m:n connection

When the Q series C24 is installed into an existing system that has an m:n system structure between the PLC CPU and external devices, and data communication is performed using the MC protocol, the following notes should be considered:

(a) Accessing the PLC using a frame for form 5

When the UC24/C24-S8 is connected on the line, it is not possible to access the PLC in the QnA compatible 4C frame (form 5) for binary code communication.

(b) Data communication between external devices

1) When data communication is performed in order to link with an external devices to perform a 1:1 communication with the PLC CPU, it is necessary to change the station number (80_H to $A0_H \rightarrow 00_H$ to $1F_H$) designated in the "Station number" and "Local station number" items in the messages on the external device side. (It is not necessary to specify this when an A compatible 1C frame is used.)
Alternatively, it is necessary to change the message frame so that it has a data order different from that of the MC protocol.
   - Station number: Designate the number of device to which data is sent
   - Local station number: Designate the number of the device that sends data

2) Perform the data communication according to Chapter 14 of the User's Manual (Application).

(c) Processing reception data on the external device side

Set the external device so that it ignores the following reception messages that are unrelated to the local station.
- The command message and the corresponding response message that are sent from other stations when accessing the PLC CPU using the MC protocol.
- Messages when accessing between external devices.

(2) Data communication using 1:n connection

When the UC24/C24-S8 is connected on the line, it is not possible to access the PLC in the QnA compatible 4C frame (format 5) for binary code communication.

POINT

Since performances and response speeds are different between the Q series C24 and the UC24/C24-S8, communication may not be performed normally when a PLC module in the A series is replaced by a Q series PLC.
When a module is changed to a Q series PLC module, make sure to check operation.

Appendix 3 Processing Time

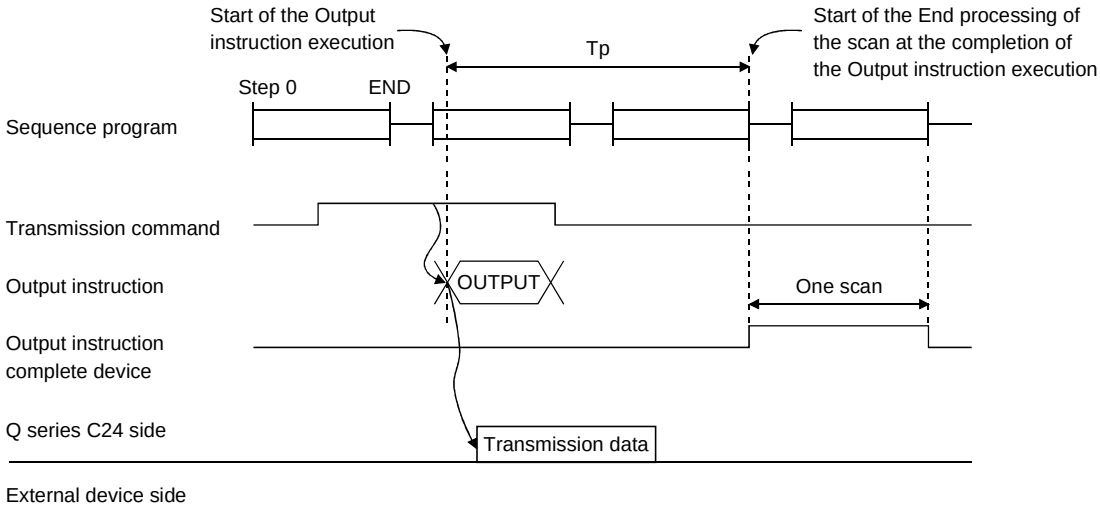
(1) Time required to process communication using the non procedure protocol (guideline)

The processing time for the Output and Input instructions can be estimated by the following formula. Note, however, that the processing time may become longer depending on other communication functions (e.g., communication using the MC protocol) and special functions (e.g., ASCII-binary conversion, transmission control) that are used at the same time.
The value obtained from the following formula should be used as a guideline for the processing time when reception or transmission only is performed using only CH1 (RS-232 connection).

(a) Output instruction

$Tp = St + (D_{le}/Cr \times 1000 + 0.07) \times Ds + 4.86$

Tp (*1) : The time from the start of execution of the Output instruction to the End processing of the sequence scan at the completion of the Output instruction execution (ms)
St : Scan time
D_{le} : Data length of 1 byte at data transmission (number of bits)
Cr : Communication rate (bps)
Ds : Number of bytes of transmission data
*1 This stands for the time range of processing (Tp).



[Calculation example]
Estimate the time required to process the Output instruction when transmitting 100 bytes of data using the non procedure protocol (unit: ms).

- Scan time : 10 ms
- Data length : 10 bits (1 start bit, 8 data bits, 1 stop bit, no parity bit)
- Communication rate : 19200 bps

$10 + (10/19200 \times 1000 + 0.07) \times 100 + 4.86 \fallingdotseq 73.94$ (ms)

(b) Input instruction

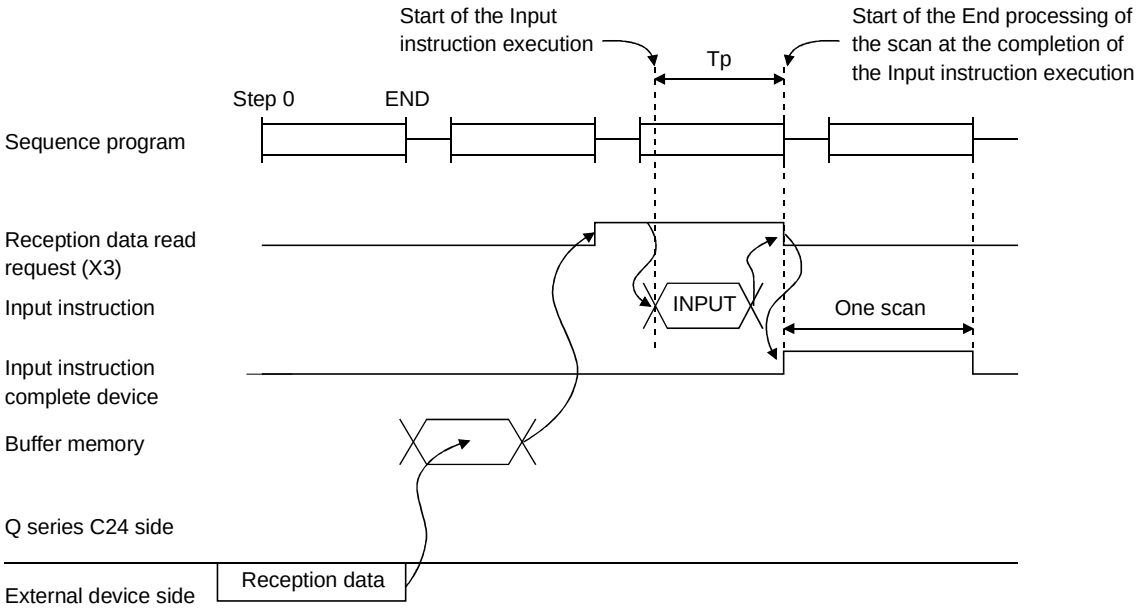
Tp = Sr + 0.09 × Dr + 14.91

Tp (*1) : Time from the start of execution of the Input instruction to the End processing of the sequence scan at the completion of the Input instruction execution (ms)

Sr : Scan time

Dr : Number of bytes of reception data

*1 This stands for the time range of processing (Tp).



[Calculation example]

Estimate the time required to process the Input instruction when receiving 100 bytes of data using the non procedure protocol (unit: ms).

- Scan time : 10 ms

10 + 0.09 × 100 + 14.91 ≒ 33.91 (ms)

App. - 14

2) Processing time of dedicated instructions
The following table shows the operation processing time (rough standard) of each dedicated instruction.
The operation processing time differs slightly depending on the system configuration and communication protocol.

Instruction name	Processing time (unit: ms)		Instruction execution condition		
	Q02CPU	QnHCPU	Transmission rate	Transmission/receive (registered) data count	Others
ONDEMAND	52.9	51.5	19200 bps	40 bytes	Send in form 3
OUTPUT	38.5	35.9		40 bytes	—
PRR	38.5	35.9		40 bytes ∗ 8 bytes × 5 frames	—
INPUT	28.5	28.4		40 bytes	—
BIDOUT	52.3	50.3		40 bytes	—
BIDIN	40.0	40.0		40 bytes	—
PUTE	798.7	791.3	—	40 bytes	—
GETE	2.1	1.0	—	40 bytes	—
SPBUSY	0.6	0.2	—	—	—
CSET	2.3	1.1	—	—	Transmission/ receive buffer setting
BUFRCVS	21.3	21.3	19200 bps	40 bytes	—

App. - 15

Appendix 4 ASCII-Code Table

The ASCII-code table is shown below. (7-bit code)
The codes 00H to 1FH indicated by the ★ are used as Q series C24 control codes. (DC codes 11H to 14H can be changed by the user.)

LSD \ MSD		0	1	2	3	4	5	6	7
		000	001	010	011	100	101	110	111

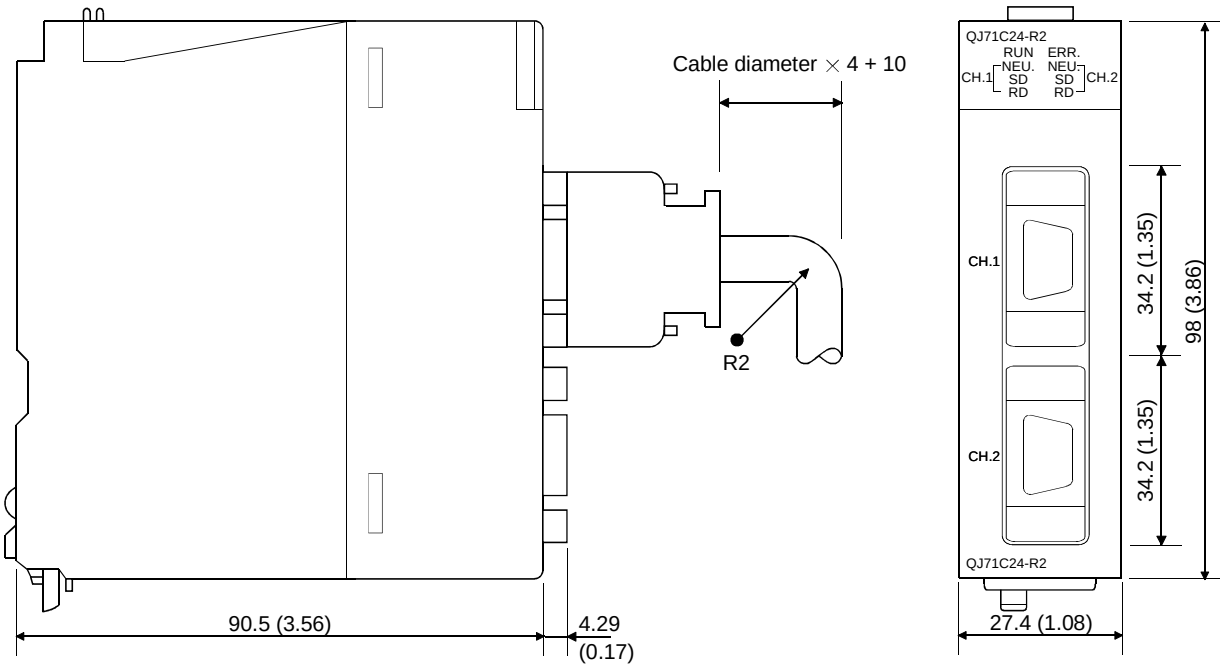
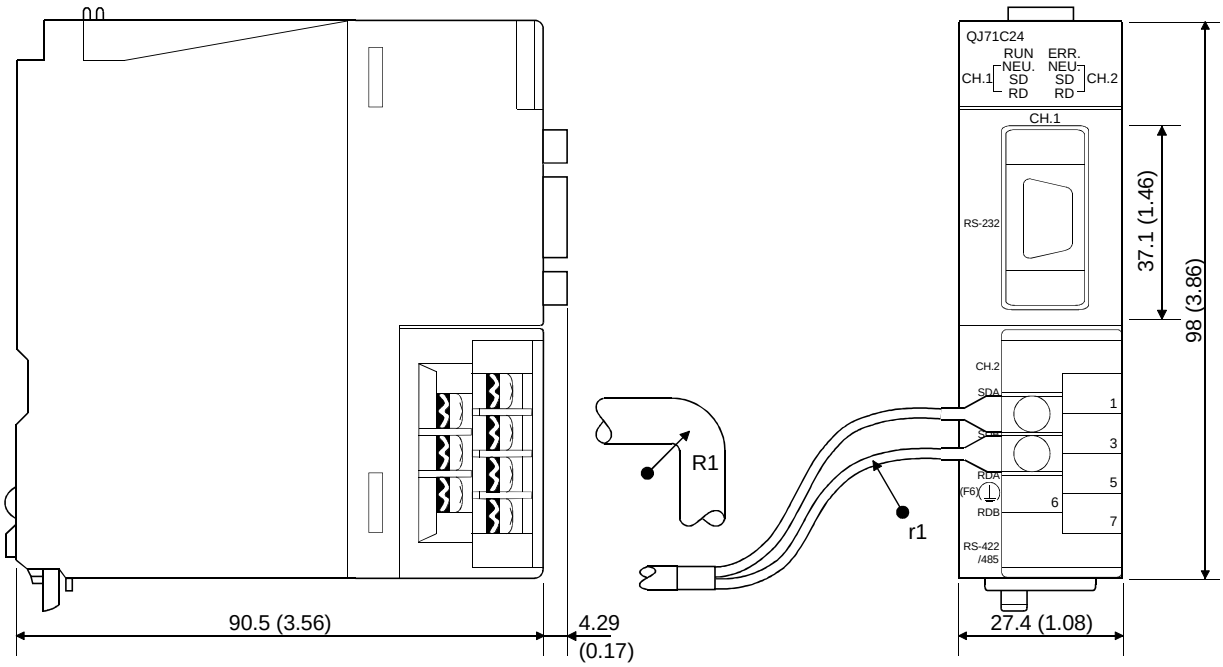
App. - 16

Appendix 5 External Dimensions





(Unit : mm (inch))

* R1 (bend radius near terminal board): Cable diameter × 4
* R2 (bend radius near connector) : Cable diameter × 4
* r1 (bend radius near crimp terminal) : Can be connected within the range over which bending is not excessive

Appendix 6 Example of Connection when a Converter is Used

The following shows an example of a connection where the RS-232 to RS-422/485 converters are used in order to communicate data using data communication functions with the MC, non-procedure, or bidirectional protocol.

The converters covered in the Appendix are as follows:

Manufacturer	Model name (Products that can be connected)	Contact	Tel No. Fax No.
EL Engineering Ltd.	EL-LINE-II	Funato-cho 7-16, Nakagawa-ku, Nagoya, 454-0805	Tel: (052) 361-2290 Fax: (052) 363-1050
System Sacom Co., Ltd.	KS-1 KS-10P KS-485	Shibuya Property West Bldg 12F, Higashi 1-32-12 , Shibuya-ku, Tokyo, 150-0011	Tel: (03) 3797-0211 Fax: (03) 3797-0231

* "Products that can be connected" indicates products whose specifications (standards) allow connection with modules of our company.
Before using them, make sure they confirm to the stated specifications (standards).

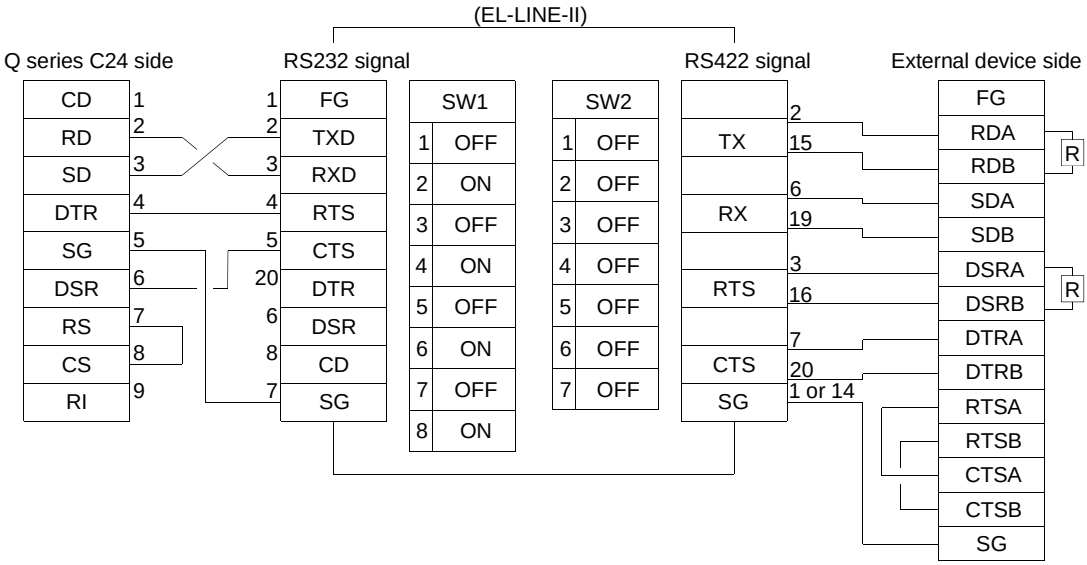
(1) Combination between available converters and connections

Q series C24 side connection interface	System configuration with external devices	External device interface	Available converter	Description No. of connection example
RS-232	1:1	RS-422	EL-LINE-II	Connection example 1
			KS-1 KS-10P	Connection example 2
		RS-485	KS-485	Connection example 3
RS-422/485	1:1, 1:n, m:n	RS-232	KS-485	Connection example 4

App. - 18

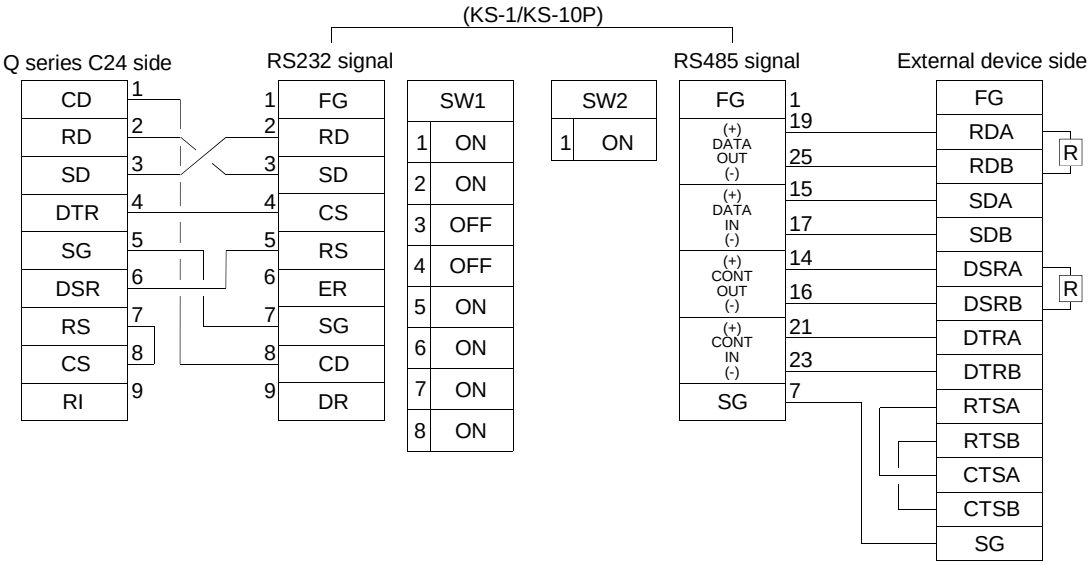
(2) Connection example

(Connection example 1)



* • The CD terminal check setting should be set to "No check" according to the explanation in Section 3.2.1 (1).
  • DC code control or DTR/DSR control becomes possible for transmission control.

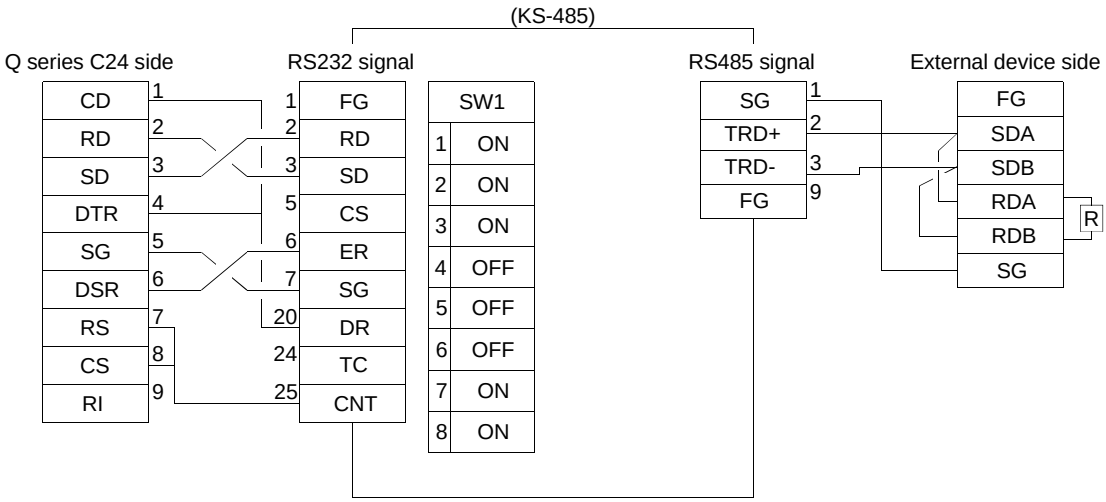
(Connection example 2)



* • The CD terminal check setting should be set to "No check" according to the explanation in Section 3.2.1 (1).
  • DC code control or DTR/DSR control becomes possible for transmission control.

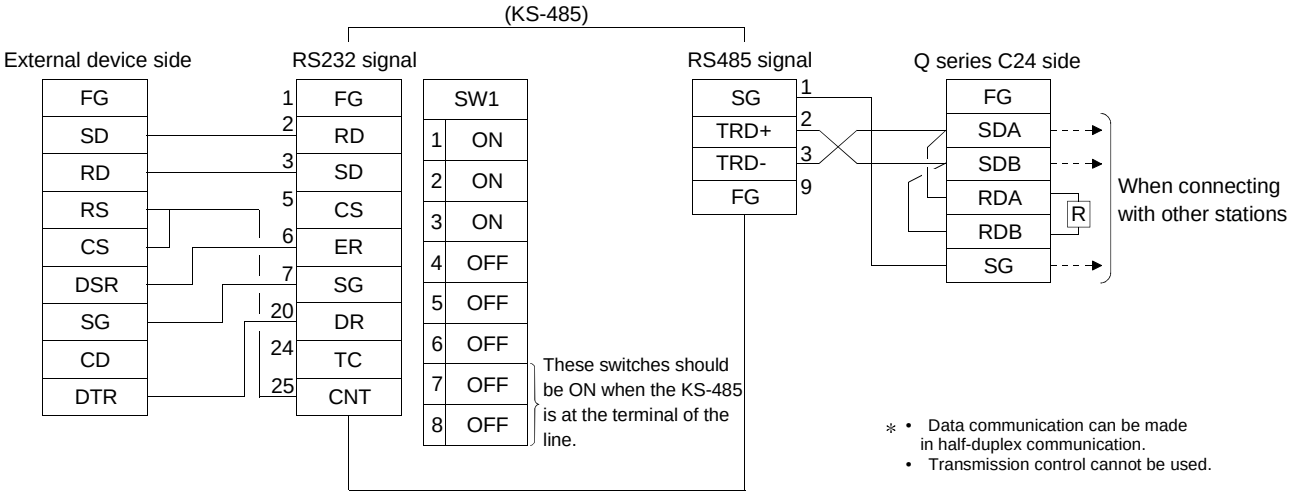
App. - 19

(Connection example 3)



∗ • Data communication can be made in half-duplex communication.
• The CD terminal check setting should be set to "No check" according to the explanation in Section 3.2.1 (1).
• Transmission control cannot be used.

(Connection example 4)



∗ • Data communication can be made in half-duplex communication.
• Transmission control cannot be used.

App. - 20

Appendix 7 MELSEC Communication Support Tool

By using the Mitsubishi communication support tool for supporting communication between the MELSEC-Q Series and personal computer, the communication program on the personal computer side connected with a computer link etc., can be simplified. The following sections explain the function overview and data link functions of the MX Links (SWnD5F-CSKP-E, hereinafter CSKP). The programming methods on personal computer side for reading/writing data to the MELSEC PLC CPU using CSKP are also explained.

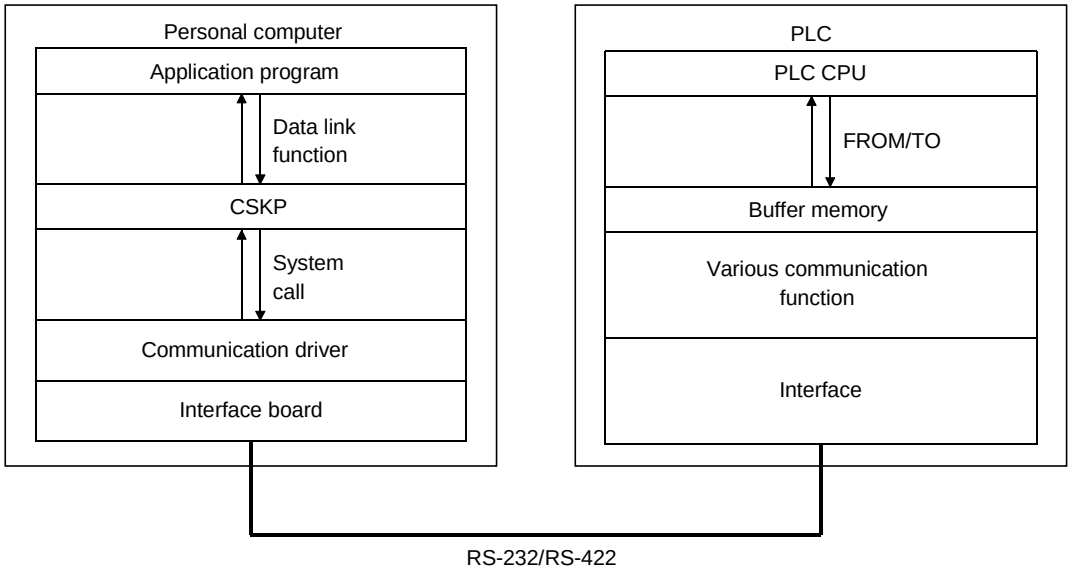
* For details on the CSKP, see the CSKP manual.

Appendix 7.1 Overview of MX Links

This section shows the overview of CSKP.

(1) The CSKP is installed into the personal computer and used.

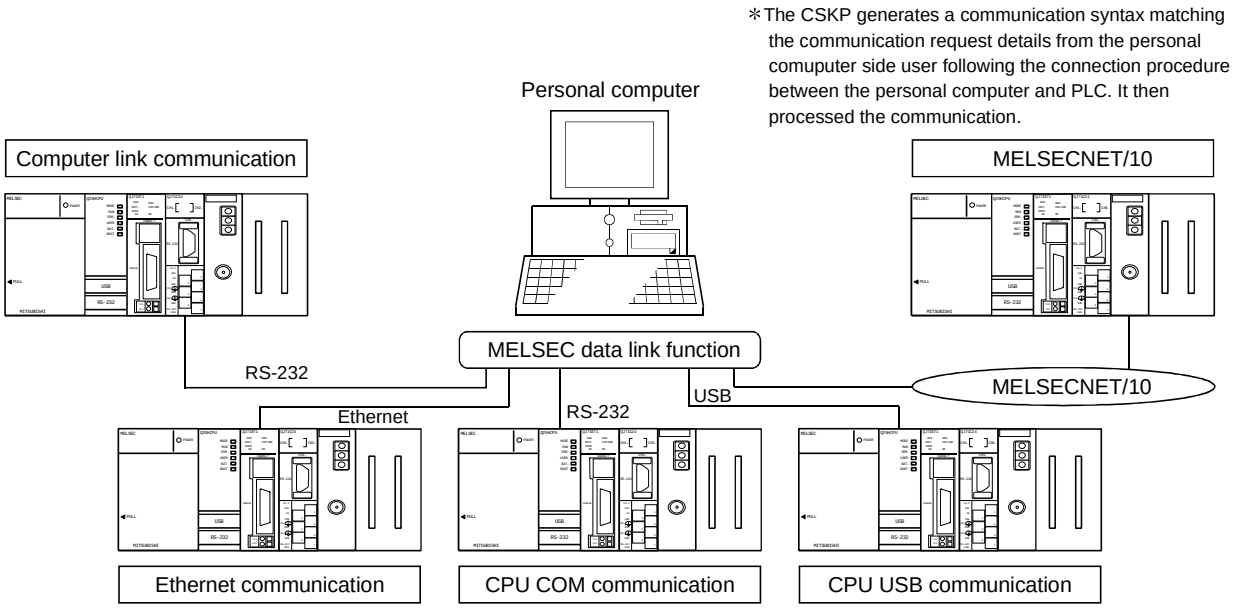
(Example) Software structure diagram for computer link connection



(2) Ample support of communication protocols

The personal computer side user can easily access the PLC's CPU by designating the connection type and communication request details using the following CSKP data link function arguments.

* The user does not need to understand the communication syntax unique to the intelligent function module on the PLC side. The connection procedure can be changed just by changing part of the program (mdOpen argument's communication channel No.) in the program created by the user.
  Once created, the user program can be used effectively.



(3) Data link functions dedicated for communicating data with PLC are supported

- Functions required for communicating data with the PLC, such as communication line open/close and device read/write, are prepared as data link functions.
- Various communication programs can be created easily, so development of the communication system using Ethernet/serial communication, etc. with the PLC side is easily.

Function name	Data link function's function
mdOpen	Initializes and opens the designated communication line channel.
mdClose	Closes the designated communication line channel.
mdSend	Writes the data in a batch to the designated device.
mdReceive	Reads the data in a batch from the designated device.
mdRandR	Reads data from a randomly designated device.
mdRandW	Writes the data to a randomly designated device.
mdDevSet	Sets (ON) the designated bit device.
mdDevRst	Resets (OFF) the designated bit device.
mdControl	Carries out remote RUN/STOP/PAUSE in respect to the designated PLC CPU.
mdTyperead	Reads the type of designated PLC CPU.

(4) Various utilities are enclosed

The communication between the PLC and personal computer can be tested and monitored with the communication diagnosis utility and device monitor utility enclosed with the product.

(5) Supporting system construction without programming

By using the CSKP along with the MX Chart (SWnD5F-OLEX-E) and MX Monitor (SWnD5F-XMOP-E), a system may be constructed without programming.

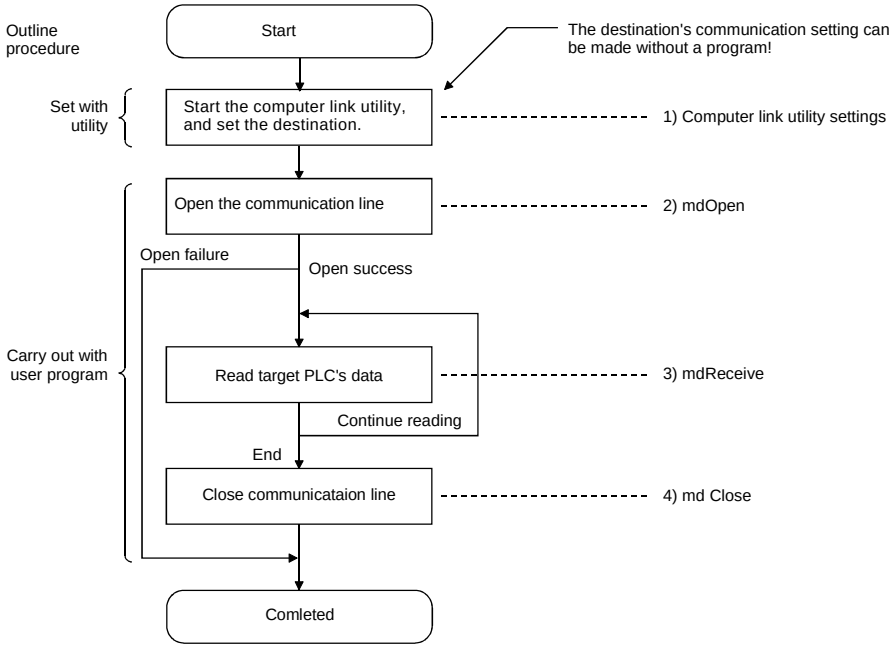
App. - 22

Appendix 7.2 Examples of Using MX Links

Programming procedures and program examples for connecting to the PLC's computer link module and the Q series C24 and accessing the PLC's CPU from a personal computer are described in this section.
For the program example, the personal computer reads the data register (D) for the Q Series PLC CPU, and displays the results on the screen.

(1) Programming procedures (Outline flow of procedures)

The flow of the data read process for creating a personal computer side program to access the PLC CPU using CSKP is shown below.



1) Computer link utility settings
   Set the computer link module/Q series C24 model (QJ71C24), module station number and COM port communication condition of the PLC to be communicated with over a computer link connection. This information is saved as a logic station No.
2) mdOpen
   This function initializes and opens the serial communication line channel (Serial port (COM port) channel number = 31 to 40).
   The path of the opened communication line is returned as the execution results.
   The path is required to execute the function (mdReceive) for reading the PLC data, and the function (mdClose) for closing the line.
3) mdReceive
   This function reads the PLC CPU's device data.
   The target PLC's logic station No., device to be read and No. of points are assigned to the argument.
4) mdClose
   This function closes the opened communication line channel.
   The communication line must be closed when reading and writing are completed.

(2) Example of programming (a Visual C++ compiler is used in the example)

The following shows a programming that reads the values of D0 to D1 of the target PLC CPU via the communication line of logical station number 0, and displays them in the MS-DOS Windows prompt for Microsoft®Windows®95 operating system, Microsoft®windows®98 operating system, Microsoft® Windows NT®Workstation4.0 operating system.

Appendix 9 Setting Value Recording Sheet

The following sheet is for recording parameter setting values set by GX Developer.
Use as many copies as needed.

* In order to review the setting values of the utility package (QSCU), print out the content of the file generated by the "Make text file" function of QSCU which can be used as the setting value recording sheet.

[Module No.]

Recording sheet 1 (Intelligent function module interrupt pointer setting)

GX Developer setting screen	Data item name		Set data	
			Setting value	Remarks
Intelligent function module interrupt pointer setting	CPU side	Interrupt pointer start No.		Input format: Decimal
		Interrupt pointer No. of modules	2 (fixed)	
	Intelligent module side	Start I/O number		Input format: Hexadecimal
		Start SI number	0 (fixed)	Input format: Decimal

Recording sheet 2 (Intelligent function module switch setting)

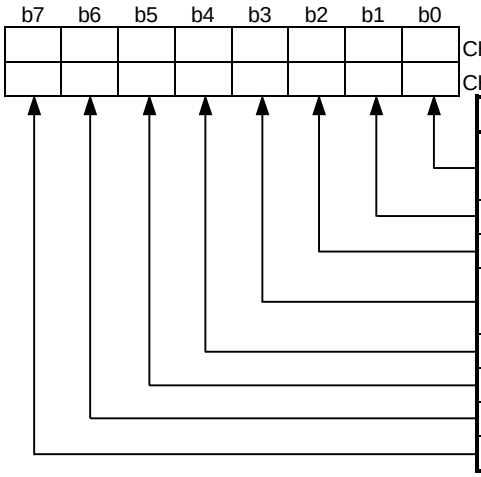
App. - 28

(GX Developer "Intelligent function module switch setting" setting values recording check sheet)

(1) Transmission setting (Enter "0" or "1" in the bit position field)



Bit	Description	OFF (0)	ON (1)	Remarks
b0	Operation setting	Independent	Linked	Always set to OFF on CH1 side.
b1	Data bit	7	8	Do not include parity bit.
b2	Parity bit	No	Yes	Vertical parity
b3	Odd/even parity	Odd	Even	Valid only when parity bit is set to Yes.
b4	Stop bit	1	2	—
b5	Sum check code	No	Yes	—
b6	Write during RUN	Prohibit	Allow	—
b7	Setting modification	Prohibit	Allow	—

(2) Communication rate setting (Enter check marks in the CH1 and CH2 fields)

CH1	CH2	Setting value	Communication speed (unit: bps)
		F_H	50
		0_H	300
		1_H	600
		2_H	1200
		3_H	2400
		4_H	4800
		5_H	9600
		6_H	14400
		7_H	19200
		8_H	28800
		9_H	38400
		A_H	57600
		B_H	115200

(3) Communication protocol setting (Enter check marks in the CH1 and CH2 fields)

CH1	CH2	Setting value	Setting data	
		0_H	GX Developer connection	
		1_H	MC protocol	Format 1
		2_H		Format 2
		3_H		Format 3
		4_H		Format 4
		5_H		Format 5
		6_H	Non procedure protocol	
		7_H	Bidirectional protocol	
		8_H	For linked operation setting	
		9_H to D_H	Setting prohibited	
		E_H	ROM/RAM/Switch test	
		F_H	Individual station recovery test

WARRANTY

Please confirm the following product warranty details before starting use.

1. Gratis Warranty Term and Gratis Warranty Range

If any faults or defects (hereinafter "Failure") found to be the responsibility of Mitsubishi occurs during use of the product within the gratis warranty term, the product shall be repaired at no cost via the dealer or Mitsubishi Service Company. Note that if repairs are required at a site overseas, on a detached island or remote place, expenses to dispatch an engineer shall be charged for.

[Gratis Warranty Term]

The gratis warranty term of the product shall be for one year after the date of purchase or delivery to a designated place.

Note that after manufacture and shipment from Mitsubishi, the maximum distribution period shall be six (6) months, and the longest gratis warranty term after manufacturing shall be eighteen (18) months. The gratis warranty term of repair parts shall not exceed the gratis warranty term before repairs.

[Gratis Warranty Range]

(1) The range shall be limited to normal use within the usage state, usage methods and usage environment, etc., which follow the conditions and precautions, etc., given in the instruction manual, user's manual and caution labels on the product.

(2) Even within the gratis warranty term, repairs shall be charged for in the following cases.

1. Failure occurring from inappropriate storage or handling, carelessness or negligence by the user. Failure caused by the user's hardware or software design.
2. Failure caused by unapproved modifications, etc., to the product by the user.
3. When the Mitsubishi product is assembled into a user's device, Failure that could have been avoided if functions or structures, judged as necessary in the legal safety measures the user's device is subject to or as necessary by industry standards, had been provided.
4. Failure that could have been avoided if consumable parts (battery, backlight, fuse, etc.) designated in the instruction manual had been correctly serviced or replaced.
5. Failure caused by external irresistible forces such as fires or abnormal voltages, and Failure caused by force majeure such as earthquakes, lightning, wind and water damage.
6. Failure caused by reasons unpredictable by scientific technology standards at time of shipment from Mitsubishi.
7. Any other failure found not to be the responsibility of Mitsubishi or the user.

2. Onerous repair term after discontinuation of production

(1) Mitsubishi shall accept onerous product repairs for seven (7) years after production of the product is discontinued. Discontinuation of production shall be notified with Mitsubishi Technical Bulletins, etc.

(2) Product supply (including repair parts) is not possible after production is discontinued.

3. Overseas service

Overseas, repairs shall be accepted by Mitsubishi's local overseas FA Center. Note that the repair conditions at each FA Center may differ.

4. Exclusion of chance loss and secondary loss from warranty liability

Regardless of the gratis warranty term, Mitsubishi shall not be liable for compensation to damages caused by any cause found not to be the responsibility of Mitsubishi, chance losses, lost profits incurred to the user by Failures of Mitsubishi products, damages and secondary damages caused from special reasons regardless of Mitsubishi's expectations, compensation for accidents, and compensation for damages to products other than Mitsubishi products and other duties.

5. Changes in product specifications

The specifications given in the catalogs, manuals or technical documents are subject to change without prior notice.

6. Product application

(1) In using the Mitsubishi MELSEC programmable logic controller, the usage conditions shall be that the application will not lead to a major accident even if any problem or fault should occur in the programmable logic controller device, and that backup and fail-safe functions are systematically provided outside of the device for any problem or fault.

(2) The Mitsubishi general-purpose programmable logic controller has been designed and manufactured for applications in general industries, etc. Thus, applications in which the public could be affected such as in nuclear power plants and other power plants operated by respective power companies, and applications in which a special quality assurance system is required, such as for Railway companies or National Defense purposes shall be excluded from the programmable logic controller applications.

Note that even with these applications, if the user approves that the application is to be limited and a special quality is not required, application shall be possible.

When considering use in aircraft, medical applications, railways, incineration and fuel devices, manned transport devices, equipment for recreation and amusement, and safety devices, in which human life or assets could be greatly affected and for which a particularly high reliability is required in terms of safety and control system, please consult with Mitsubishi and discuss the required specifications.

Anexo 33: Información sobre sensores y dispositivos por comunicar

Dispositivo de vibraciones TAC 84c

Anemómetro

PT100: Sensor de temperatura

SEG: Relé de protección por bajo voltaje o baja frecuencia

Part no. 954184C

TAC 84C is used to monitor lowfrequent wing vibration in wind turbines.
A four character display shows measuring values and parameters.
The sensor is mounted in the rear end of the nacelle.
Self-test of sensor, see table for sensor error.
LED indications of relay status and revolution signal.
User adjustment of vibration fail level in m/s².
User adjustment of revolution fail level.
User adjustment of band-pass filter frequency and bandwidth.
The measuring principle: Sampling of data. Digital signal processing of the sampled values.
RS485 communication port. Text protocol and Modbus protocol.
11 pin plug-in socket.
Used with vibration sensor type VS05 nr. 9590100, sensitivity 240-650 mV/g. (typical 400 mV/g)

TAC 84C Vibration Guard / RS485

Keyboard operation

The program version is displayed after power-up.
Press "NEXT" for next parameter. Activation of the "NEXT" key in more than 1 sec. moves the cursor to the top of the list.
Press "PARAM" for parameter text presentation. At a new press "PARAM" the text presentation is ended.
To alter parameters press "PARAM" and "NEXT" at the same time.
The first digit is flashing and can be altered by pressing "PARAM".
Press "NEXT" to move on to next digit.
At the fourth activation of the "NEXT" key the altering is ended.
Please note that the filter bandwidth can be changed in 31 steps only by pressing "PARAM".

* Presentation only (no parameter settings).
** Sensor check disabled when parameter is 0 RPM.
*** RPM level disabled when parameter is 0 RPM.

**** Error codes 1 = High vibration 2 = High RPM
4 =Sensor error RPM 8 = Sensor error vibration
Note: With several errors, this will be a combination.
E.g. 5 = High vibration (1) + sensor error RPM (4)

++ Those parameters can be altered by pressing "PARAM" down in 4 sec. and pressing å "NEXT" at the same time more than 4 times. Parameters are parameters and should not normally be altered.
Baud rate: 0= off, 1= 4800, 2= 9600, 3= 19200, (8N1)

The PV 01-2 is an anemometer, used in connection with Mita-Teknik wind turbine electronics for starting and stopping the wind turbine.

- Opto-electronic sensor pickup action.
- Registers wind speed from 2 to 30 m/s.
- The rotor is made of varnished stainless steel.
- The casing in PVC.
- Equipped with 2 m PVC cable.
- Fastening: External thread M 28 x 2.
- Part.no. 7690220

PT100 Sensor

- The PT100 Sensors are used for flexible temperature surveillance
- Easy mounting
- Direct connection to IC/WP-Controllers
- Correction of distance via a 3-core or 4-core system

Description

PT100 is delivered in various mechanical designs for easy mounting at generators, bearings, gear box, or other places in connection with wind turbines.

The sensor compensates for the cable length between the WP or IC control unit and the PT100 sensor so that an accurate temperature measurement is achieved.

5.3.4 Display of the activation storage (FLSH/NOFL)
5.3.5 Parameterswitch/external trigger for the fault recorder
5.4 Protection parameters
5.4.1 Parameter setting of over- and under-voltage supervision
5.4.2 Number of measuring repetitions (T) for frequency functions
5.4.3 Threshold of frequency supervision
5.4.4 Tripping delays for the frequency elements
5.4.5 Parameter setting of vector surge supervision (*MRN3-1*)
5.4.6 Parameter setting of frequency gradient (*MRN3-2*)
5.4.7 Voltage threshold value for frequency and vector surge measuring (df/dt at *MRN3-2*)
5.4.8 Adjustment of the slave address
5.4.9 Setting of Baud-rate (applies for Modbus Protocol only)
5.4.10 Setting of parity (applies for Modbus Protocol only)
5.5 Adjustment of the fault recorder
5.5.1 Number of the fault recordings
5.5.2 Adjustment of trigger occurences
5.5.3 Pre-trigger time (T_{pre})
5.6 Adjustment of the clock
5.7 Additional functions
5.7.1 Setting procedure for blocking the protection functions
5.8 Indication of measuring values
5.8.1 Measuring indication
5.8.2 Min./Max.- values
5.8.3 Unit of the measuring values displayed
5.8.4 Indication of fault data
5.9 Fault memory
5.9.1 Reset
5.9.2 Erasure of fault storage

6 Relay testing and commissioning
6.1 Power-On
6.2 Testing the output relays
6.3 Checking the set values
6.4 Secondary injection test
6.4.1 Test equipment
6.5 Example of test circuit
6.5.1 Checking the input circuits and measuring functions
6.5.2 Checking the operating and resetting values of the over/undervoltage functions
6.5.3 Checking the relay operating time of the over/undervoltage functions
6.5.4 Checking the operating and resetting values of the over/underfrequency functions
6.5.5 Checking the relay operating time of the over/underfrequency functions
6.5.6 Checking the vector surge function
6.5.7 Checking the external blocking and reset functions
6.6 Primary injection test
6.7 Maintenance

7 Technical data
7.1 Measuring input circuits
7.2 Common data
7.3 Setting ranges and steps
7.3.1 Interface parameter
7.3.2 Parameters for the fault recorder
7.4 Output relays

8 Order form

1 Introduction and application

The *MRN3* is a universal mains decoupling device and covers the protection requirements from VDEW and most other utilities for the mains parallel operation of power stations.

- Over/ and undervoltage protection,
- over/ and underfrequency protection,
- extremely fast decoupling of generator in case of mains failure (*MRN3-1*) or
- rate of change of frequency df/dt (*MRN3-2*)

Because of combination of three protectional functions in one device the *MRN3* is a very compact mains decoupling device. Compared to the standardly used single devices it has a very good price/performance ratio.

For applications where the single protection functions are required SEG can offer the single *MR*-relays as follows:

- *MRU3-1* four step independent over-/ and undervoltage protection (also used for generator earth fault protection).
- *MRU3-2* two step independent over-/ and undervoltage protection with evaluation of the symmetrical voltage components.
- *MRF3* four step independent over/ and underfrequency protection and two step frequency gradient supervision df/dt.
- *MRG2* generator mains monitor / vector surge detection.

Important:
For additional common data of all *MR*-relays please refer to technical description "*MR* - Digital Multifunctional Relays".

2 Features and characteristics

- Microprocessor technology with watchdog,
- effective analog low pass filter for suppressing harmonics when measuring frequency and vector surge,
- digital filtering of the measured values by using discrete Fourier analysis to suppress higher harmonics and d.c. components induced by faults or system operations,
- integrated functions for voltage, frequency and vector surge in one device as well as single voltage, frequency and vector surge devices,
- two parameter sets,
- voltage supervision each with two step under-/ and overvoltage detection,
- frequency supervision with three step under-/ or overfrequency (user setting),
- completely independent time settings for voltage and frequency supervision,
- adjustable voltage threshold value for blocking frequency and vector surge measuring,
- display of all measuring values and setting parameters for normal operation as well as tripping via a alphanumerical display and LEDs,
- display of measuring values as primary quantities
- Storage of trip values and switching-off time (t_{CBFP}) of 5 fault occurences (fail-safe of voltage),
- recording of up to eight fault occurences with time stamp
- for blocking the individual functions by the external blocking input, parameters can be set according to requirement,
- user configurable vector surge measurement 1-of-3 or 3-of-3,
- reliable vector surge measuring by exact calculation algorithm,
- suppression of indication after an activation (LED flash),
- free assignment for output relays,
- display of date and time,
- in complience with VDE 0435, part 303 and IEC 255,
- serial data exchange via RS485 interface possible; alternatively with SEG RS485 Pro-Open Data Protocol or Modbus Protocol.

3 Design

3.1 Connections

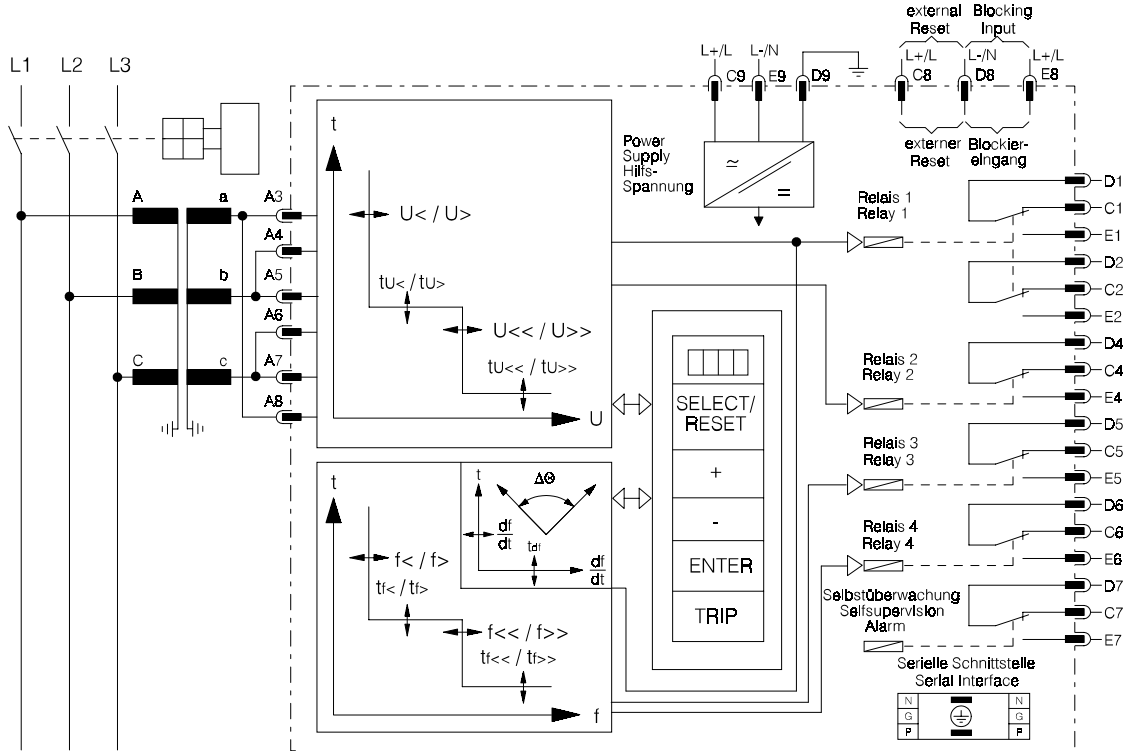

Figure 3.1: Connection diagram MRN3-1 and MRN3-2

3.1.1 Analog input circuits

The analog input voltages are galvanically decoupled by the input transformers of the device, then filtered and finally fed to the analog digital converter. The measuring circuits can be applied in star or delta connection (refer to chapter 4.3.1).

3.1.2 Blocking input

The blocking function can be set according to requirement. By applying the auxiliary voltage to D8/E8, the previously set relay functions are blocked (refer to 4.8 and 5.7.1).

3.1.3 Reset input

Please refer to chapter 5.9.1.

3.1.4 Output relays

The *MRN3* is equipped with 5 output relays. Apart from the relay for self-supervision, all protective functions can be optionally assigned:

- Relay 1: C1, D1, E1 and C2, D2, E2
- Relay 2: C3, D3, E3 and C4, D4, E4
- Relay 3: C5, D5, E5
- Relay 4: C6, D6, E6
- Relay 5: Signal self-supervision (internal failure of the unit) C7, D7, E7

All trip and alarm relays are working current relays, the relay for self supervision is an idle current relay.

3.1.5 Fault recorder

The *MRN3* has a fault value recorder which records the measured analog values as instantaneous values.
The instantaneous values

U_{L1}; U_{L2}; U_{L3} for star connection
or U_{12}; U_{23}; U_{21} for delta connection

are scanned at a raster of 1.25 ms (at 50 Hz) and 1.041 ms (at 60 Hz) and saved in a cyclic buffer. It is possible to store 1 - 8 fault occurences with a total recording time of 16 s (with 50 Hz) and 13.33 s (with 60 Hz) per channel.

Storage division

Independent of the recording time, the entire storage capacity can be divided into several cases of disturbance with a shorter recording time each. In addition, the deletion behaviour of the fault recorder can be influenced.

No writing over

If 2, 4 or 8 recordings are chosen, the complete memory is divided into the relevant number of partial segments. If this max. number of fault event has been exceeded, the fault recorder block any further recordings in order to prevent that the stored data are written over. After the data have been read and deleted, the recorder to ready again for further action.

Writing over

If 1, 3 or 7 recordings are chosen, the relevant number of partial segments is reserved in the complete memory. If the memory is full, a new recording will always write over the oldest one.

The memory part of the fault recorder is designed as circulating storage. In this example 7 fault records can be stored (written over).

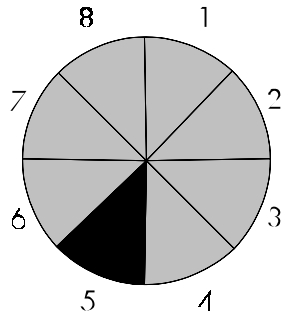

Figure 3.2: Division of the memory into 8 segments, for example

Memory space 6 to 4 is occupied.
Memory space 5 is currently being written in

Since memory spaces 6, 7 and 8 are occupied, this example shows that the memory has been assigned more than eight recordings. This means that No. 6 is the oldest fault recording and No. 4 the most recent one.

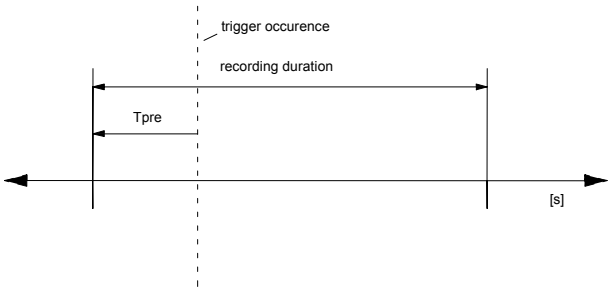

Figure 3.3: Basic set-up of the fault recorder

Each memory segment has a specified storage time which permits setting of a time prior to the trigger event.

Via the interface RS485 the data can be read and processed by means of a PC (HTL/PL-Soft4). The data is graphically edited and displayed. Binary tracks are recorded as well, e.g. activation and trip.

Table 3.6: Date and time

The window for parameter setting is located behind the measured value display. The parameter window can be accessed via the <SELECT/RESET> key.

3.3 LEDs

All LEDs (except LED RS, min. and max.) are two-coloured. The LEDs on the left side, next to the alpha-numerical display light up green during measuring and red after tripping.

The LEDs below the push button <SELECT/RESET> are lit green during setting and inquiry procedure of the setting values which are printed on the left side next to the LEDs. The LEDs will light up red after parametrizing of the setting values next to their right side.

The LED marked with letters RS lights up during setting of the slave address of the device for serial data communication.

The LED marked with the letters FR is alight while the fault recorder is being adjusted.

3.4 Front plate

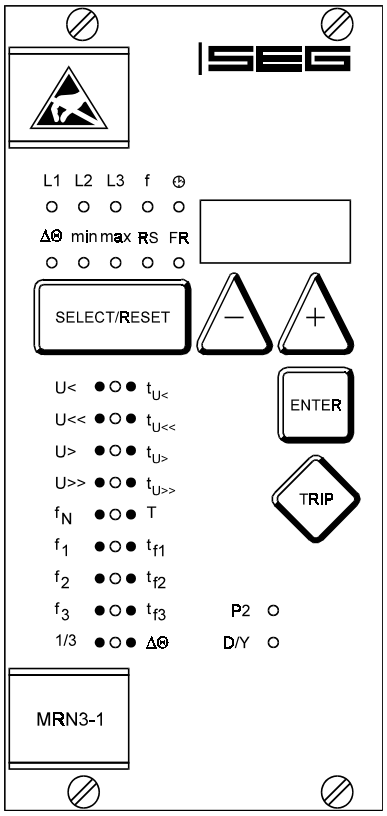

Figure 3.4: Front plate MRN3-1

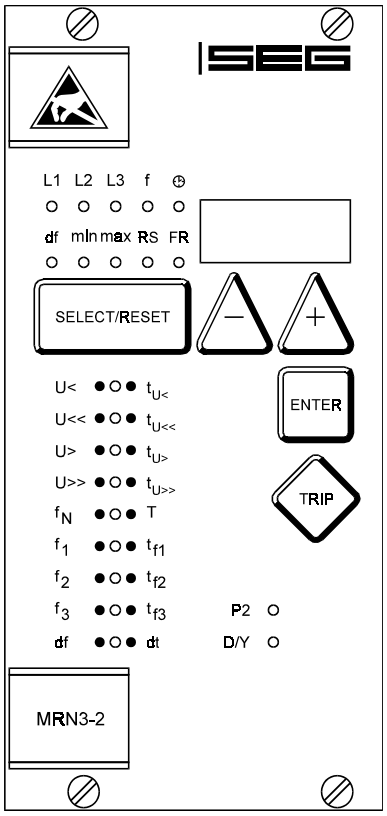

Figure 3.5: Front plate MRN3-2

4 Working principle

4.1 Analog circuits

The input voltages are galvanically insulated by the input transformers. The noise signals caused by inductive and capacitive coupling are supressed by an analog R-C filter circuit.

The analog voltage signals are fed to the A/D-converter of the microprocessor and transformed to digital signals through Sample- and Hold- circuits. The analog signals are sampled with a sampling frequency of 16 x f_N, namely, a sampling rate of 1.25 ms for every measuring quantity, at 50 Hz.

4.2 Digital circuits

The essential part of the *MRN3* relay is a powerful microcontroller. All of the operations, from the analog digital conversion to the relay trip decision, are carried out by the microcontroller digitally. The relay program is located in an EPROM (Electrically-Programmable-Read-Only-Memory). With this program the CPU of the microcontroller calculates the three phase voltage in order to detect a possible fault situation in the protected object.

For the calculation of the voltage value an efficient digital filter based on the Fourier Transformation (DFFT - Discrete Fast Fourier Transformation) is applied to suppress high frequency harmonics and d.c. components caused by fault-induced transients or other system disturbances. The microprocessor continuously compares the measured values with the preset thresholds stored in the parameter memory (EEPROM). If a fault occures an alarm is given and after the set tripping delay has elapsed, the corresponding trip relay is activated.

The relay setting values for all parameters are stored in a parameter memory (EEPROM - Electrically Erasable Programmable Read Only Memory), so that the actual relay settings cannot be lost, even if the power supply is interrupted.
The microprocessor is supervised by a built-in "watchdog" timer. In case of a failure the watchdog timer resets the microprocessor and gives an alarm signal via the output relay "self supervision".

4.3 Voltage supervision

The voltage element of *MRN3* has the application in protection of generators, consumers and other electrical equipment against over-/and undervoltage.
The relay is equipped with a two step independent three-phase overvoltage (U>, U>>) and undervoltage (U<, U<<) function with completely separate time and voltage settings.
In delta connection the phase-to-phase voltages and in star connection the phase-to-neutral voltages are continuously compared with the preset thresholds.

For the overvoltage supervision the highest, for the undervoltage supervision of the lowest voltage of the three phases are decisive for energizing.

4.3.1 Selection of star or delta connection

All connections of the input voltage transformers are led to screw terminals. The nominal voltage of the device is equal to the nominal voltage of the input transformers. Dependent on the application the input transformers can be connected in either delta or star. The connection for the phase-to-phase voltage is the delta connection. In star connection the measuring voltage is reduced by $1/\sqrt{3}$. During parameter setting the connection configuration either Y or Δ has to be adjusted.

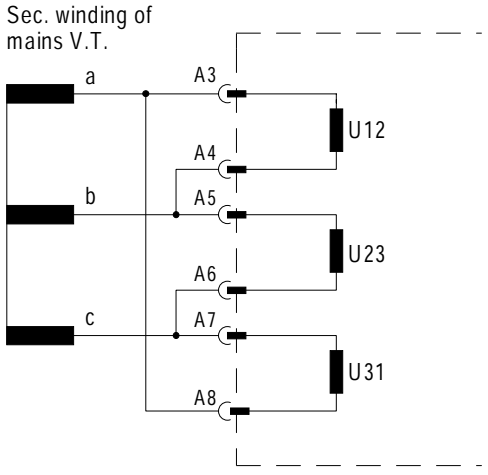

Figure 4.1: Input v.t.s in delta connection (Δ)

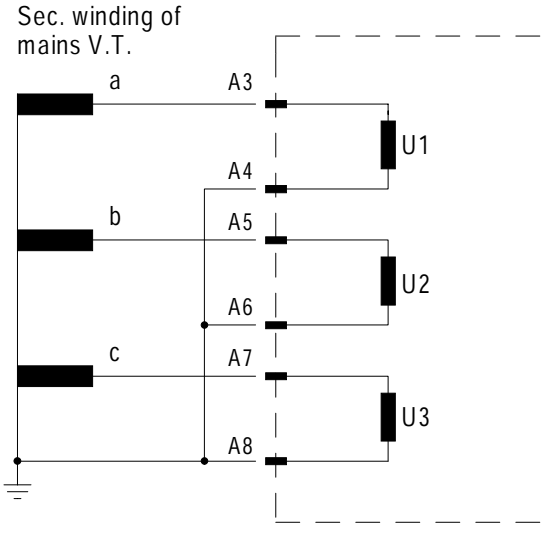

Figure 4.2: Input v.t.s in star connection (Y)

4.4 Principle of frequency supervision

The frequency element of *MRN3* protects electrical generators, consumers or electrical operating equipment in general against over- or underfrequency.
The relay has independent three frequency elements f_1 - f_3 with a free choice of parameters, with separate adjustable pickup values and delay times.

The measuring principle of the frequency supervision is based in general on the time measurement of complete cycles, whereby a new measurement is started at each voltage zero passage. The influence of harmonics on the measuring result is thus minimized.

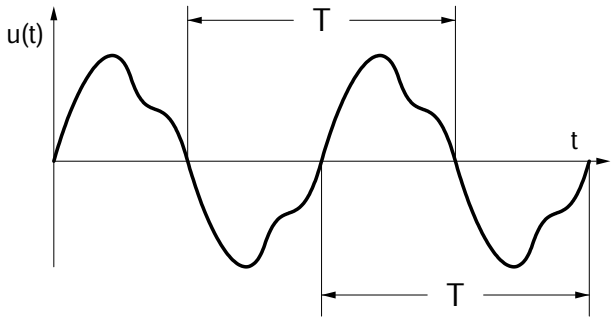

Figure 4.3: Determination of cycle duration by means of zero passages.

In order to avoid false tripping during occurence of interference voltages and phase shifts the relay works with an adjustable measuring repetition. (refer to chapter 5.4.2)

Frequency tripping is sometimes not desired by low measured voltages which for instance occur during alternator acceleration. All frequency supervision functions can be blocked with the aid of an adjustable voltage threshold U_B in case the measured voltages value is below this value.

4.5 Measuring of frequency gradient (*MRN3-2*)

Electrical generators running in parallel with the mains, e.g. industrial internal power supply plants, should be separated from the mains when failure in the intrasystem occurs for the following reasons:

- It must be prevented that the electrical generators are damaged when mains voltage recovering asynchrone, e.g. after a short interruption.
- The industrial internal power supply must be maintained.

A reliable criterion of detecting mains failure is the measurement of the rate of change of frequency df/dt. Precondition for this is a load flow via the mains coupling point. At mains failure the load flow changing then spontaneously leads to an increasing or decreasing frequency. At active power deficit of the internal power station a linear drop of the frequency occurs and a linear increase occurs at power excess. Typical frequency gradients during application of "mains decoupling" are in the range of 0.5 Hz/s up to over 2 Hz/s. The *MRN3* detects the instantaneous frequency gradient df/dt of each mains voltage period in an interval of one half period each. Through multiple evaluation of the frequency gradient in sequence the continuity of the directional change (sign of the frequency gradient) is determined. Because of this special measuring procedure a high safety in tripping and thus a high stabilty against transient processes, e.g. switching procedure are reached. The total switching off time at mains failure is between 60 ms and 80 ms depending on the setting.

4.6 Vector surge supervision (*MRN3-1*)

The vector surge supervision protects synchronous generators in mains parallel operation due to very fast decoupling in case of mains failure. Very dangerous are mains auto reclosings for synchronous generators. The mains voltage returning after 300 ms can hit the generator in asynchronous position. A very fast decoupling is also necessary in case of long time mains failures. Generally there are two different applications:

a) Only mains parallel operation no single operation:
In this application the vector surge supervision protects the generator by tripping the generator circuit breaker in case of mains failure.

b) Mains parallel operation and single operation:
For this application the vector surge supervision trips the mains circuit breaker. Here it is insured that the gen.-set is not blocked when it is required as the emergency set.

A very fast decoupling in case of mains failures for synchronous generators is known as very difficult. Voltage supervision units cannot be used because the synchronous alternator as well as the consumer impedance support the decreasing voltage.

For this the mains voltage drops only after some 100 ms below the pickup threshold of voltage supervision relays and therefore a safe detection of mains auto reclosings is not possible with this kind of relay.

Frequency relays are partial unsuitable because only a highly loaded generator decreases its speed within 100 ms. Current relays detect a fault only when short-circuit type currents exist, but cannot avoid their development. Power relays are able to pickup within 200 ms, but they cannot prevent power to rise to short-circuit values too. Since power changes are also caused by sudden loaded alternators, the use of power relays can be problematic.

Whereas the *MRN3-1* detects mains failures within 60 ms without the restrictions described above because they are specially designed for applications where very fast decoupling from the mains is required.

Adding the operating time of a circuit breaker or contactor, the total disconnection time remains below 150 ms. Basic requirement for tripping of the generator/mains monitor is a change in load of more than 15 - 20% of the rated load. Slow changes of the system frequency, for instance at regulating processes (adjustment of speed regulator) do not cause the relay to trip.

Trippings can also be caused by short-circuits within the grid, because a voltage vector surge higher than the preset value can occur. The magnitude of the voltage vector surge depends on the distance between the short-circuit and the generator. This function is also of advantage to the Power Utility Company because the mains short-circuit capacity and consequently the energy feeding the short-circuit is limited.

To prevent a possible false tripping the vector surge measuring can be blocked at a set low input voltage (refer to 5.4.7). The undervoltage lockout acts faster then the vector surge measurement.

Vector surge tripping is blocked by a phase loss so that a VT fault (e.g. faulty VTs fuse) does not cause false tripping.
When switching on the aux. voltage or measuring voltage , the vector surge supervision is blocked for 5 s (refer to chapter 4.8).

Note:
In order to avoid any adverse interference voltage effects, for instance from contactors or relays, which may cause overfunctions, *MRN3-1* should be connected separately to the busbar.

4.6.1 Measuring principle of vector surge supervision

When a synchronous generator is loaded, a rotor displacement angle is build between the terminal voltage (mains voltage U1) and the synchronous internal voltage (Up). Therefore a voltage is difference ΔU is built between Up and U1 (Fig. 4.4).

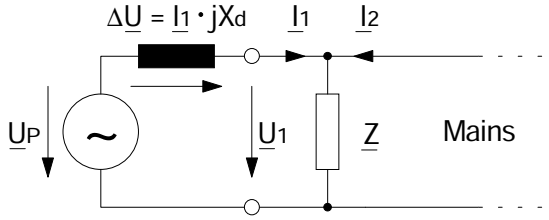

Figure 4.4: Equivalent circuit at synchronous generator in parallel with the mains

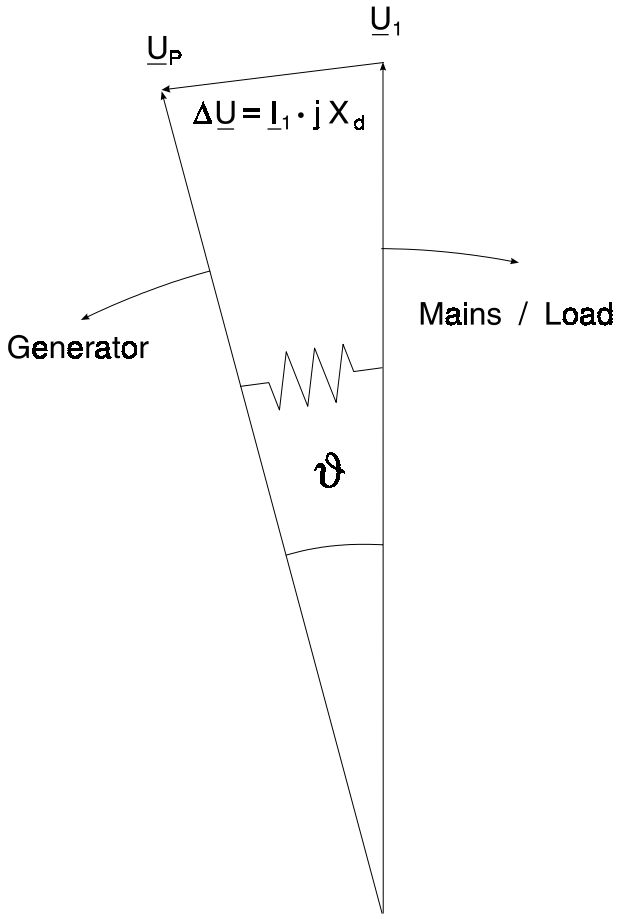

Figure 4.5: Voltage vectors at mains parallel operation

The rotor displacement angle ϑ between stator and rotor is depending of the mechanical moving torque of the generator shaft. The mechanical shaft power is balanced with the electrical feeded mains power, and therefore the synchronous speed keeps constant (Fig. 4.5).

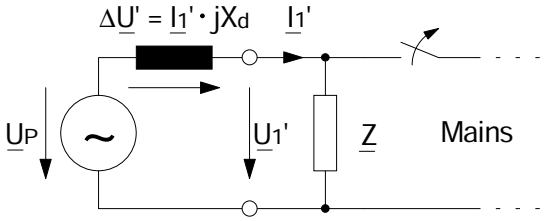

Figure 4.6: Equivalent circuit at mains failure

In case of mains failure or auto reclosing the generator suddenly feeds a very high consumer load. The rotor displacement angle is decreased repeatedly and the voltage vector $\underline{U}_1$ changes its direction ($\underline{U}_1$') (Fig. 4.6 and 4.7).

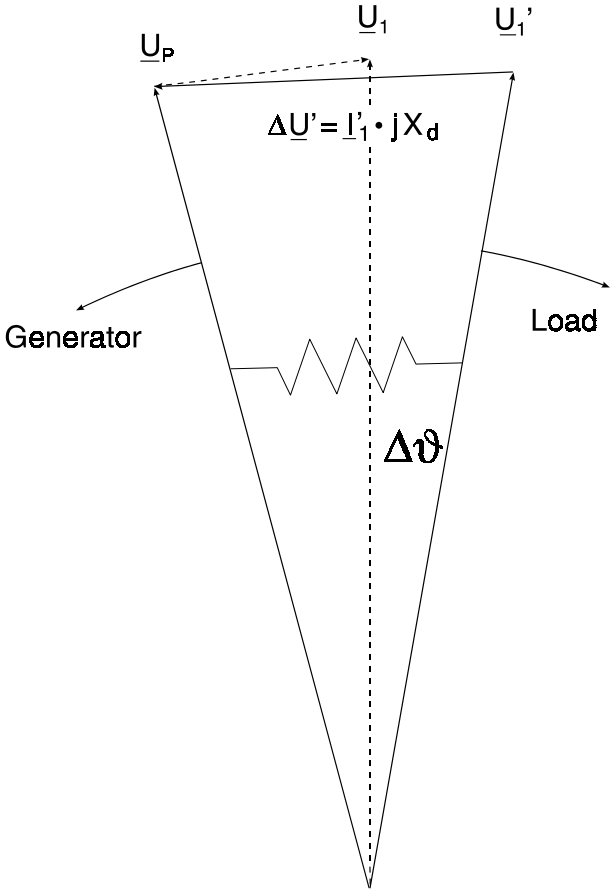

Figure 4.7: Voltage vectors at mains failure

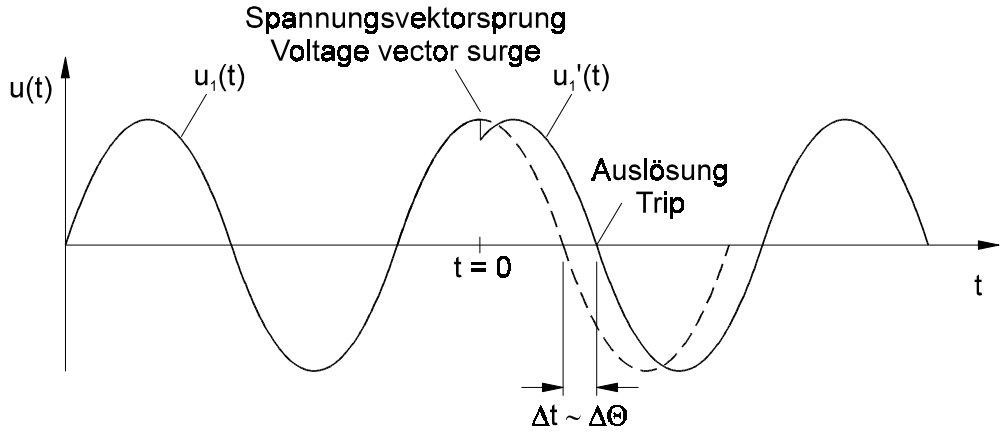

Figure 4.8: Voltage vector surge

As shown in the voltage/time diagram the instantaneous value of the voltage jumps to another value and the phase position changes. This is named phase or vector surge.

The *MRN3-1* measures the cycle duration. A new measuring is started at each voltage zero passage. The measured cycle duration is internally compared with a quartz stable reference time and from this the deviation of the cycle duration of the voltage signal is ascertained. In case of a vector surge as shown in fig. 4.8, the zero passage occurs either earlier or later. The established deviation of the cycle duration is in compliance with the vector surge angle.
If the vector surge angle exceeds the set value, the relay trips immediately.

Tripping of the vector surge is blocked in case of loss of one or more phases of the measuring voltage.

Tripping logic for vector surge measurement:

The vector surge function of the *MRN3-1* supervises vector surges in all three phases at the same time. Tripping of the relay can be adjusted for an one phase vector surge (more sensitive measurement). For this the parameter 1/3 has to be set to "1Ph". When the parameter 1/3 is set to "3Ph", tripping of the vector surge element occurs only if the vector surge angle exceeds the set value in all three phases at the same time.

Application hint

Although the vector surge relay guarantees very fast and reliable detection of mains failures under nearly all operational conditions of mains parallel running alternators, the following borderline cases have to be considered accordingly:

a) None or only insignificant change of power flow at the utility connection point during mains failures.

This can occure during peak lopping operation or in CHP stations (Combined Heat and Power) where the power flow between power station and the public grid may be very low. For detection of a vector surge at parallel running alternators, the load change must be at least 15 - 20% of the rated power. If the active load at the utility connection point is regulated to a minimal value and a high resistance mains failure occurs, then there are no vector surge nor power and frequency changes and the mains failure is not detected.

This can only happen if the public grid is disconnected near the power station and so the alternators are not additionally loaded by any consumers. At distant mains failures the synchronous alternators are abruptly loaded by remaining consumers which leads directly to a vector surge and so mains failure detection is guaranteed.
If such a situation occurs the following has to be taken into account:

In case of an undetected mains failure, i.e. with the mains coupling C.B. closed, the vector surge relay reacts upon the first load change causing a vector surge and trips the mains C.B.

For detecting high resistance mains failures a minimum current relay with an adjustable trip delay can be used. A trip delay is needed to allow regulating actions where the current may reach "zero" at the utility connection point. At high resistance mains failures, the mains coupling C.B. is tripped by the minimum current relay after the time delay.

To prevent asynchronous switching on, an automatic reclosing of the public grid should be not possible during this time delay.

A further measure could be, that the load regulation at the utility connection point guarantees a minimum power flow of 15 - 20% of rated power.

b) Short circuit type loading of the alternators at distant mains failures

At any distant mains failure, the remaining consumers cause sudden short circuit type loading of the power station generators. The vector surge relay detects the mains failure in about 60 ms and switches off the mains coupling C.B. The total switch off time is about 100 - 150 ms. If the generators are provided with an extremely fast short circuit protection e.g. able to detect di/dt, the alternators might be switched off unselectively by the generator C.B., which is not desireable because the power supply for the station is endangered and later on synchronized changeover to the mains is only possible after manual reset of the overcurrent protection.

To avoid such a situation, the alternator C.B.s must have a delayed short circuit protection. The time delay must be long enough so that mains decoupling by the vector surge relay is guaranteed.

4.7 Voltage threshold value for frequency measuring

At low measuring voltages, e.g. during generator start-up, frequency and vector surge or df/dt-measuring is perhaps not desired.

By means of the adjustable voltage threshold value $U_B<$, functions f_1 - f_3, df/dt or $\Delta\Theta$ are blocked if the measured voltage falls below the set value.

4.8 Blocking function

No.	Dynamic Behaviour	U</<<	U>/>>	f_1, f_2, f_3	$\Delta\Theta$	df/dt

Table 5.1: Possible indication messages on the display

5.2 Setting procedure

In this paragraph the settings for all relay parameters are described in detail. For parameter setting a password has to be entered first (please refer to 4.4 of description "*MR*-Digital Multifunctional Relays").

5.3 Systemparameter

5.3.1 Display of residual voltage U_E as primary quantity (U_{prim}/U_{sec})

The residual voltage can be shown as primary measuring value. For this parameter the transformation ratio of the VT has to be set accordingly. If the parameter is set to "sek", the measuring value is shown as rated secondary voltage.

Example:
The voltage transformer used is of 10 kV/100 V. The transformation ratio is 100 and this value has to be set accordingly. If still the rated secondary voltage should be shown, the parameter is to be set to 1.

5.3.2 Δ/Y – Switch over

Depending on the mains voltage conditions, the input voltage transformers can be operated in delta or Y connection. Change-overs are effected via the <+> and the <-> keys and stored with <ENTER>.

5.3.3 Setting of nominal frequency

For proper functioning it is necessary to first adjust the rated frequency (50 oder 60 Hz).

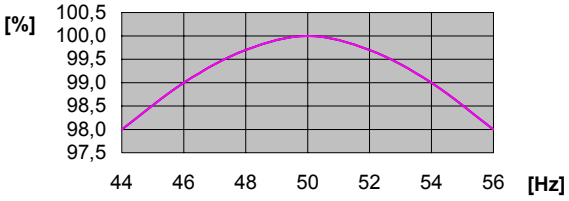
For this a distinction has to be made between the settings v = 50 Hz / f = 50 Hz or v = 60 Hz / f = 60 Hz
The difference lies in the method of voltage measuring. With the setting "v" = 50/60 Hz voltage measuring is independent of the existing frequency. This means, the voltage value can be correctly measured between 30 Hz and 80 Hz without adverse effects from the frequency.

With the setting "f" = 50/60 Hz the measured voltage value is influenced by the frequency. (see Table 5.2)

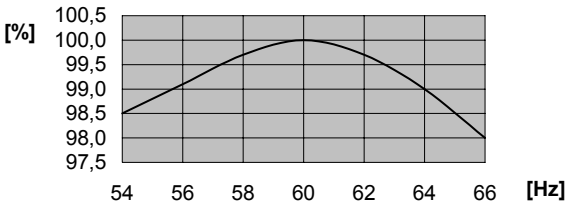
This difference in settings is required for the fault recorder. If the fault recorder is to be used, the setting must be f = 50 Hz or f = 60 Hz.
The different designations "f" or "v" have no influence on any of the other functions.

All frequency functions are determined by setting the nominal frequency, i.e. whether the set frequency thresholds are evaluated as over- or underfrequency (see also chapter 5.4.4). Also the cycle duration (20 ms at 50 Hz and 16.67 ms at 60 Hz) derives from this setting which determines the minimum tripping delay for frequency elements f_1 - f_3 with an adjustable multiplier (see also chapter 5.4.5).
During setting of the nominal frequency a value in Hz is shown on the display.

Declination of measuring value at 50Hz



Declination of measuring value at 60Hz



Setting	v = 50	f = 50	v = 60	f = 60
Rated frequency	50 Hz	50 Hz	60 Hz	60 Hz
Influence on voltage measurement	none	0.5..1%/Hz (see table 5.2)	none	0.5..1%/Hz (see table 5.2)
Fault recorder	Recording distorted**	Recording correct***	Recording distorted**	Recording correct***
Influence on all other functions	none	none	none	none

Table 5.2: Deviation of measured value at 50 or 60 Hz

* Setting is important for differentiation between over- and underfrequency
** Sample rate is variably adjusted to the momentarily measured frequency. 16 samples are always measured in one period.
*** Sample rate setting is fixed to 50 Hz or 60 Hz. 16 samples per 20 ms or 16.67 ms are always measured.

5.3.4 Display of the activation storage (FLSH/NOFL)

If after an activation the existing current drops again below the pickup value, e.g. U<, without a trip has been initiated, LED U< signals that an activation has occured by flashing fast. The LED keeps flashing until it is reset again (push button <RESET>). Flashing can be suppressed when the parameter is set to NOFL.

5.3.5 Parameterswitch/external trigger for the fault recorder

By means of the parameter-change-over switches it is possible to activate two different parameter sets. Switching over of the parameter sets can either be done by means of software or via the external inputs RESET or blocking input. Alternatively, the external inputs can be used for Reset or blocking and for the triggering of the fault recorder.

Software-parameter	Blocking input used as	RESET input used as
SET1	Blocking input	RESET input
SET2	Blocking input	RESET input
B_S2	Parameter switch	RESET input
R_S2	Blocking input	Parameter switch
B_FR	External triggering of the fault recorder	Reset input
R_FR	Blocking input	External triggerung of the fault recorder
S2_FR	Parameter switch	External triggerung of the fault recorder

With the settings SET1 or SET2 the parameter set is activated by software. Terminals C8/D8 and D8/E8 are then available as external reset input or blocking input.

With the setting B_S2 the blocking input (D8, E8) is used as parameter-set change-over switch. With the setting R_S2 the reset input (D8, E8) is used as parameter-set change-over switch. With the setting B_FR the fault recorder is activated immediately by using the blocking input. On the front plate the LED FR will then light up for the duration of the recording. With the setting R_FR the fault recorder is activated via the reset input. With the setting S2_FR parameter set 2 can be activated via the blocking input and/or the fault recorder via the reset input. The relevant function is then activated by applying the auxiliary voltage to one of the external inputs.

With the setting R_FR the fault recorder is activated via the reset input. With the setting S2_FR parameter set 2 can be activated via the blocking input and/or the fault recorder via the reset input.
The relevant function is then activated by applying the auxiliary voltage to one of the external inputs.

Important note:
When functioning as parameter change over facility, the external input RESET is not available for resetting. When using the external input BLOCKING the protection functions must be deactivated by software blocking separately (refer to chapter 5.7.1).

5.4 Protection parameters

5.4.1 Parameter setting of over- and undervoltage supervision

The setting procedure is guided by two coloured LEDs. During setting of the voltage thresholds the LEDs U<, U<<, U> and U>> are lit green. During setting of the trip delays $t_{U>}$, $t_{U>>}$, $t_{U<}$ and $t_{U<<}$ the according LEDs light up red.

Thresholds of the voltage supervision

During setting of the threshold U>, U>>, U< and U<< the displays shows the voltages directly in volt. The thresholds can be changed by the <+> <-> push buttons and stored with <ENTER>.

The undervoltage supervision (U< and U<<) as well as the overvoltage supervision (U> and U>>) can be deactivated by setting the threshold to "EXIT".

Tripping delay of voltage supervision

During setting of the tripping delays $t_{U<}$, $t_{U<<}$, $t_{U>}$ and $t_{U>>}$ the display shows the value directly in seconds. The tripping delay is changed via the push button <+> and <-> in the range of 0,04 s to 50 s and can be stored with the push button <ENTER>.
When setting the tripping delay to "EXIT" the value is infinit meaning only warning, no tripping.

5.4.2 Number of measuring repetitions (T) for frequency functions

In order to avoid false tripping of the unit at short voltage drops of the system voltage or interference voltages, *MRN3* works with an adjustable measuring repetition. When the instantaneous frequency measuring value exceeds (at overfrequency) or falls below (at underfrequency) the set reference value, the counter is incremented, otherwise the counter is decremented down to the minimum value of 0. Only when the counter exceeds the value adjusted at T, alarm is given and after the tripping delay of the frequency element has elapsed the tripping command is given.
The setting range for T is between 2 - 99.

Recommendation for setting:
For short tripping times, e.g. for machine protection or for mains decoupling T should be set in the range from 2 - 5.
At precision measurements, e.g. exact measurement of the system frequency a setting of T in the range from 5 - 10 is recommended.

5.4.3 Threshold of frequency supervision

The frequency supervision of *MRN3* has three frequency elements independent from each other. Acc. to setting the pickup value above or below the nominal frequency, these elements can be used for over- or under frequency supervision.

Dependent on the preset nominal frequency f_N the pickup values from 30 Hz up to 70 Hz at f_N = 50 Hz and from 40 Hz to 80 Hz at f_N = 60 Hz can be set. During setting of the pickup values f_1 - f_3 the display shows the values in Hz. A value of for instance 49,8 Hz is indicated with "4980".

The function of the individual frequency elements can be deactivated by setting the pickup values to "EXIT". The setting value "EXIT" corresponds to the rated frequency.

5.4.4 Tripping delays for the frequency elements

Tripping delays t_{f1} - t_{f3} of the four frequency elements can be set independently from $t_{f1\,min}$ - 50 s. The minimum tripping delay $t_{f1\,min}$ of the relay depends upon the number of set measuring repetitions T (periods) and amounts to:

T	$t_{f\,min}$
2....49	(T+1)·20 ms
50....69	(T - 49)·50 ms + 1 s
70....99	(T - 69)·100 ms + 2 s

When setting the tripping delay to "EXIT" by pressing push button <+> up to the maximum setting value, the corresponding tripping relay is blocked. Pickup of the frequency element is however displayed on the front plate by the corresponding LED, an assigned alarm relay is also activated. This setting applies to 50 Hz and 60 Hz.

5.4.5 Parameter setting of vector surge supervision (*MRN3-1*)

Both the vector surge angle ΔΘ as well as the tripping logic concerning the vector surge have to be adjusted for a vector surge supervision.
If the tripping logic is set to 1-of-3 (= "1Ph" on the display), the relay trips as soon as the measured vector surge angle has exceeded the set value ΔΘ in one of the three phases. This is the more sensitive adjustment when compared with the three phase tripping logic 3-of-3 (= "3Ph" on the display), where tripping occurs only if the vector surge angle exceeds the set value in all three phases.

We recommend to choose the one phase tripping logic "1Ph". Only if this adjustment is too sensitive, adjustment "3Ph" should be used.

The recommended setting of the vector surge angle ΔΘ in a low impedance mains is 4 - 6 degrees. This setting is sufficient in most cases, because low impedance mains do not have a vector surge greater than this value. In case of an auto reclosing, this value is exceeded. In high impedance mains the setting should be 10° to 12° to avoid failure tripping when switching on or switching off big consumer loads.

The vector surge function of this device can be checked as follows:

a) Generator in isolated operation: Switching off and on of loads (approx. 20% of the nominal generator capacity) must trip the relay. Later in normal isolated operation the tripping of the relay is inhibited.

b) In mains parallel operation switching on and switching off of consumer loads and controlling the governor of the prime mover should not trip the relay.

If possible the test described under a) and b) should be double checked by a real auto reclosing.

Threshold for the vector surge supervision

When the pickup value of the vector surge supervision is set, a value in angular degree is indicated at the display. The pickup value requested can be adjusted by pushbuttons <+> and <-> in the range of 2° to 22°. LED ΔΘ lights up red during this procedure.

5.4.6 Parameter setting of frequency gradient (*MRN3-2*)

The pickup value of frequency gradient (parameter df) can be set between 0.2 to 10 Hz/s. The number of measuring repetitions (parameter dt) can be set between 2 - 64 cycles. This parameter defines the number of df/dt measurements, which have to exceed the set value, before tripping.

Setting information:
The power difference after mains failure causes a change in frequency, which can approximately be calculated as follows:

$$\frac{df}{dt} = -\frac{f_N}{T_A} \cdot \Delta P$$

with
f_N = rated frequency in Hz
T_A = starting time at rated torque
ΔP = per unit power deficit with reference to the rated active power of the generator

If the inertia time constant is known and a power difference given, the frequency gradient can be estimated by the a.m. equation. At a supposed power difference of 20% and an inertia time constant of 10 s, the frequency gradient is 1 Hz/s.

To prevent false trippings at loading, deloading or failure signals, we would recommend a setting value for dt of minimum 4 cycles.

5.4.7 Voltage threshold value for frequency and vector surge measuring (df/dt at *MRN3-2*)

Correct frequency measuring or vector surge measuring cannot be obtained if the system voltage is very low, for instance during generator start up or voltage failure. False tripping of the *MRN3* in such cases is prevented by an adjustable voltage threshold U_B. If the system voltage is below this threshold, these functions of the relay are blocked.
During adjustment of U_B< LEDs f and ΔΘ or df light up in the upper display part.

5.4.8 Adjustment of the slave address

By pressing push buttons <+> and <-> the slave address can be set in the range of 1 - 32. During this adjustment the LED RS lights up.

5.4.9 Setting of Baud-rate (applies for Modbus Protocol only)

Different transmission rates (Baud rate) can be set for data transmission via Modbus Protocol.
The rate can be changed by push buttons <+> and <-> and saved by pressing <ENTER>.

5.4.10 Setting of parity (applies for Modbus Protocol only)

The following three parity settings are possible :

- "even" = even
- "odd" = odd
- "no" = no parity check

The setting can be changed by push buttons <+> and <-> and saved by pressing <ENTER>.

5.5 Adjustment of the fault recorder

The *MRI3* is equipped with a fault recorder (see chapter 3.7). Three parameters can be determined.

5.5.1 Number of the fault recordings

The max. recording time is 16 s at 50 Hz or 13.33 s at 60 Hz.
The number of max. recordings requested has to be determined in advance. There is a choice of (1)* 2, (3)* 4 or (7)* 8 recordings and dependent on this the duration of the individual fault recordings is defined, i.e.

(1)* 2 recordings for a duration of 8 s (with 50 Hz) (6.66 s with 60 Hz)
(3)* 4 recordings for a duration of 4 s (with 50 Hz) (3.33 s with 60 Hz)
(7)* 8 recordings for a duration of 2 s (with 50 Hz) (1,66 s with 60 Hz)
* is written over when a new trigger signal arrives

Caution:
If the fault recorder is used, the frequency should be set to f = 50 Hz or f = 60 Hz (see chapter 5.3.3).

5.5.2 Adjustment of trigger occurences

There is a choice between four different occurences:

P_UP (PickUP)	Storage is initiated after recognition of a general activation.
TRIP	Storage is initiated after a trip has occured.
A_PI (After Pickup)	Storage is initiated after the last activation threshold was fallen short of.
TEST	Storing is activated by simultaneous actuation of the keys <+> and <->. During the recording time the display shows "Test".

5.5.3 Pre-trigger time (T_{pre})

By the time T_{pre} it is determined which period of time prior to the trigger occurence should be stored as well. It is possible to adjust a time between 0.05s and the max. recording interval (2, 4 and 8s). With keys <+> and <-> the values can be changed and with <ENTER> be saved.

5.6 Adjustment of the clock

When adjusting the date and time, LED ◷ lights up.
The adjustment method is as follows:

Date :	Year	Y=00
	Month	M=00
	Day	D=00
Time :	Hour	h=00
	Minute	m=00
	Second	s=00

The clock starts with the set date and time as soon as the supply voltage is switched on. The time is safeguarded against short-term voltage failures (min. 6 minutes).

Note:
The window for parameter setting is located behind the measured value display. The parameter window can be accessed via the <SELECT/RESET> key.

5.7 Additional functions

5.7.1 Setting procedure for blocking the protection functions

The blocking function of the *MRN3* can be set according to requirement. By applying the aux. voltage to D8/E8, the functions chosen by the user are blocked. Setting of the parameter should be done as follows:

- When pressing push buttons <ENTER> and <TRIP> at the same time, message "BLOC" is displayed (i.e. the respective function is blocked) or "NO_B" (i.e. the respective function is not blocked). The LED allocated to the first protection function U< lights red.
- By pressing push buttons <+> <-> the value displayed can be changed.
- The changed value is stored by pressing <ENTER> and entering the password.
- By pressing the <SELECT/RESET> push button, any further protection function which can be blocked is displayed.
- Thereafter the menu is left by pressing <SELECT/RESET> again.
- If the <SELECT/RESET> key is actuated again, the blocking menu is left and the assignment mode is accessed^.

Function	Description	Display	LED
U<	Undervoltage step 1	BLOC	red
U<<	Undervoltage step 2	BLOC	red
U>	Overvoltage step 1	NO_B	red
U>>	Overvoltage step 2	NO_B	red
f1	Frequency step 1	BLOC	red
f2	Frequency step 2	BLOC	rec
f3	Frequenzstufe 3	NO_B	red
ΔΘ	Vector surge	BLOC	red
df/dt	Frequency changing rate	BLOC	red

Table 5.3: Blockadefunktion für twei Parametersätze

Assignment of the output relays:
Unit *MRN3* has five output relays. The fifth output relay is provided as permanent alarm relay for self supervision is normally on. Output relays 1 - 4 are normally off and can be assigned as alarm or tripping relays to the voltage functions which can either be done by using the push buttons on the front plate or via serial interface RS485. The assignment of the output relays is similar to the setting of parameters, however, only in the assignment mode. The assignment mode can be reached only via the blocking mode.
By pressing push button <SELECT/RESET> in blocking mode again, the assignment mode is selected.

The relays are assigned as follows: LEDs U<, U<<, U> and U>>, f1, f2, f3 are two-coloured and light up green when the output relays are assigned as alarm relays and $t_{U<}$, $t_{U<<}$, $t_{U<}$, $t_{U<<}$, tf1, tf2, tf3 df/dt and ΔΘ red as tripping relays.

Definition:
Alarm relays are activated at pickup.
Tripping relays are only activated after elapse of the tripping delay.

After the assignment mode has been activated, first LED U< lights up green. Now one or several of the four output relays can be assigned to under voltage element U< as alarm relays. At the same time the selected alarm relays for under voltage element 1 are indicated on the display. Indication "1_ _ _" means that output relay 1 is assigned to this under voltage element. When the display shows "_ _ _ _", no alarm relay is assigned to this under voltage element. The assignment of output relays 1 - 4 to the current elements can be changed by pressing <+> and <-> push buttons. The selected assignment can be stored by pressing push button <ENTER> and subsequent input of the password. By pressing push button <SELECT/RESET>, LED U< lights up red. The output relays can now be assigned to this voltage element as tripping relays.

Relays 1 - 4 are selected in the same way as described before. By repeatedly pressing of the <SELECT/RESET> push button and assignment of the relays all elements can be assigned separately to the relays. The assignment mode can be terminated at any time by pressing the <SELECT/RESET> push button for some time (abt. 3 s).

Note:
- The function of jumper J2 described in general description "MR Digital Multifunctional Relays" does not apply for *MRN3*. For relays without assignment mode this jumper is used for parameter setting of alarm relays (activation at pickup or tripping).

A form is attached to this description where the setting requested by the customer can be filled-in. This form is prepared for telefax transmission and can be used for your own reference as well as for telephone queries.

Relay function		Output relays				Display-	Corresponding
		1	2	3	4	Indication	LED
U<	alarm		X			_ 2 _ _	U<; green
tU<	tripping	X				1 _ _ _	tU< red
U<<	alarm		X			_ 2 _ _	U<< green
tU<<	tripping	X				1 _ _ _	tU<< red
U>	alarm		X			_ 2 _ _	U> green
tU>	tripping	X				1 _ _ _	tU> red
U>>	alarm		X			_ 2 _ _	U>> green
tU>>	tripping	X				1 _ _ _	tU>> red
f1	alarm			X		_ _ 3 _	f1 green
tf1	tripping	X				1 _ _ _	tf1 red
f2	alarm			X		_ _ 3 _	f2 green
tf2	tripping	X				1 _ _ _	tf2 red
f3	alarm			X		_ _ 3 _	f3 green
tf3	tripping	X				1 _ _ _	tf3 red
$\Delta\Theta$	tripping				X	_ _ _ 4	$\Delta\Theta$ red
df/dt	tripping				X	_ _ _ 4	df/dt red

Tabelle 5.4: Example of assignment matrix of the output relay (default settings).

5.8 Indication of measuring values

5.8.1 Measuring indication

In normal operation the following measuring values can be displayed.

Voltages (LED L1, L2, L3 green)
- In star connection all phase-to-neutral voltages
- In delta connection all phase-to-phase voltages

Frequency (LED f green *MRN3-1*)
Vector surge (LED $\Delta\Theta$ green)
Frequency gradient df/dt (LED df green; *MRN3-2*)

Min. and max. values prior to the last reset:
- Frequency (LED f + min or f + max)
- Vector surge (LED $\Delta\Theta$ + min or $\Delta\Theta$ + max)
- Frequency gradient (LED df + min or df + max)

5.8.2 Min./Max.- values

The *MRN3* offers a minimum/maximum storage each for the measuring values of the vector surge as well as the frequency gradient. These min./max. values are mainly used to appraise the system quality. Always the highest and lowest values of each cycle are measured and stored until the next reset.

Min./max. frequency measuring:
The *MRN3* ascertains the actual frequency from each cycle of the system voltage. These measuring values are entered into the min./max. storage. The latest entered min./max. values replace the previously stored values.

Dependent on the adjustment of dt and tripping delay, it is possible that the stored min./max. values are higher than the tripping threshold without causing a trip. The reason for this is storage of instantaneous values.

Min./Max. measuring of the frequency gradient:
The procedure described above applies also to storage of min./max. values of df/dt measurement. Since each instantaneous df/dt value is stored, high values can occur which, however, do not cause any tripping.

This can for instance happen during switching procedures where high positive and negative df/dt values occur, but they do not cause any tripping due to the special measuring method.

Min./max. vector surge measuring :
The procedure described above applies also to storage of min./max. values of vector surge measuring. Since each instantaneous $\Delta\Theta$ value is stored, also here high values are possible which, however, do not cause any tripping.

These min./max. measurements are of great advantage for long-time analysis of the grid quality.

As to operation :
After each reset (ref. 5.9.1) the min./max. storages are cleared. As from this instant there is no time limit for the min./max. storage until the next reset.
By repeatedly pressing the <SELECT/RESET> push button, the measuring values of the min./max. storage can be queried. The respective LEDs light up at the same time; e.g. during minimum frequency is displayed, LEDs "f" and "min" light up.

5.8.3 Unit of the measuring values displayed

The measuring values can optionally be shown in the display as a multiple of the "sec" rated value (x In) or as primary current (A). According to this the units of the display change as follows:

Indication as	Range	Unit
sec. voltage	000V – 999V	V
primary voltage	.000 – 999V	V
	1K00 – 9K99	KV
	10K0 – 99K9	KV
	100K – 999K	KV
	1M00 – 3M00	MV

Table 5.5: Units of the display

5.8.4 Indication of fault data

All faults detected by the relay are indicated on the front plate optically. For this purpose, the four LEDs (L1, L2, L3, f) and the four function LEDs (U<, U<<, U>, U>>, f1, f2, f3, $\Delta\Theta$ und df/dt) are equipped at *MRN3*. Not only fault messages are transmitted, the display also indicates the tripped protection function. If, for example an overcurrent occurs, first the respective phase LED will light up. LED I> lights up at the same time. After tripping the LEDs are lit permanently.

5.9 Fault memory

When the relay is energized or is energized or trips, all fault data and times are stored in a non-volatile memory manner. The *MRN3* is provided with a fault value recorder for max. five fault occurrences. In the event of additional trippings always the oldest data set is written over.

For fault indication not only the trip values are recorded but also the status of LEDs. Fault values are indicated when push buttons <-> or <+> are pressed during normal measuring value indication.

- Normal measuring values are selected by pressing the <SELECT/RESET> button.
- When then the <-> button is pressed, the latest fault data set is shown. By repeated pressing the <-> button the last but one fault data set is shown etc. For indication of fault data sets abbreviations FLT1, FLT2, FLT3, ... are displayed (FLT1 means the latest fault data set recorded). At the same time the parameter set active at the occurence is shown.
- By pressing <SELECT/RESET> the fault measuring values can be scrolled.
- By pressing <+> it can be scrolled back to a more recent fault data set. At first FLT8, FLT7, ... are always displayed.When fault recording is indicated (FLT1 etc), the LEDs flash in compliance with the stored trip information, i.e. those LEDs which showed a continuous light when the fault occured are now blinking blinking to indicate that it is not a current fault. LEDs which were blinking blinking during trip conditions, (element had picked up) just briefly flash.
- If the relay is still in trip condition and not yet reset (TRIP is still displayed), no measuring values can be shown.
- To delete the trip store, the push button combination <SELECT/RESET> and <->, has to be pressed for about 3s. The display shows "wait".

Recorded fault data:

Measuring	Displayed value	Corresponding LED
Voltage	L1; L2; L3; L1/L2; L2/L3; L3/L1	L1; L2; L3
Frequency	f; f min f max	f; min; max
Frequency changing rate	df	df
Vektorsprung	$\Delta\Theta$	$\Delta\Theta$
Time stamp		
Date:	Y = 99	🕒
	M = 03	🕒
	D = 10	🕒
Time:	h = 17	🕒
	m = 21	🕒
	s = 14	🕒

5.9.1 Reset

All relays have the following three possibilities to reset the display of the unit as well as the output relay at jumper position J3=ON.

Manual Reset
- Pressing the push button <SELECT/RESET> for some time (about 3 s)

Electrical Reset
- Through applying auxiliary voltage to C8/D8

Software Reset
- The software reset has the same effect as the <SELECT/RESET> push button (see also communication protocol of RS485 interface)

The display can only be reset when the pickup is not present anymore (otherwise "TRIP" remains in display).

During resetting of the display the parameters are not affected.

5.9.2 Erasure of fault storage

To delete the trip store, the push button combination <SELECT/RESET> and <->, has to be pressed for about 3s. The display shows "wait".

6 Relay testing and commissioning

The following test instructions should help to verify the protection relay performance before or during commissioning of the protection system. To avoid a relay damage and to ensure a correct relay operation, be sure that:

- The auxiliary power supply rating corresponds to the auxiliary voltage on site.
- The rated frequency and rated voltage of the relay correspond to the plant data on site.
- The voltage transformer circuits are connected to the relay correctly.
- All signal circuits and output relay circuits are connected correctly.

6.1 Power-On

NOTE!
Prior to switch on the auxiliary power supply, be sure that the auxiliary supply voltage corresponds to the rated data on the type plate.

Switch on the auxiliary power supply to the relay and check that the message "ISEG" appears on the display and the self supervision alarm relay (watchdog) is energized (Contact terminals D7 and E7 closed).
It may happen that the relay is tripped because of under- voltage condition after power-on. (The message "TRIP" on the display and LED L1, L2, L3 and U< light up red). An undervoltage condition has been detected after power-on, because no input voltages are applied to the relay. In this case:

- Press the push button <ENTER>, thus entering into the setting mode. Now set the parameters U< and U<< to "EXIT" to block the undervoltage functions. After that, press the <SELECT/RESET> for app. 3 s to reset the LEDs and "TRIP" message.
- The undervoltage tripping after power on can also be eliminated by applying three phase rated voltages after power-on and reset the LED and "TRIP" message.
- Apply auxiliary voltage to the external blocking input (Terminals E8/D8) to inhibit the undervoltage functions (refer to 6.5) and press the <SELECT/RESET> for app. 3 s to reset the LEDs and "TRIP" message.

6.2 Testing the output relays

NOTE!
Prior to commencing this test, interrupt the trip circuit to the circuit breaker if tripping is not desired.

By pressing the push button <TRIP> once, the display shows the first part of the software version of the relay (e.g. „D08-"). By pressing the push button <TRIP> twice, the display shows the second part of the software version of the relay (e.g. „4.01". The software version should be quoted in all correspondence. Pressing the <TRIP> button once more, the display shows "PSW?". Please enter the correct password to proceed with the test. The message "TRI?" will follow. Confirm this message by pressing the push button <TRIP> again. All output relays should then be activated and the self supervision alarm relay (watchdog) be deenergized one after another with a time interval of 1 second. Thereafter, reset all output relays back to their normal positions by pressing the push button <SELECT/RESET>.

6.3 Checking the set values

By repeatedly pressing the push button <SELECT>, all relay set values may be checked. Set value modification can be done with the push button <+><-> and <ENTER>. For detailed information about that, please refer to chapter 4.3 of the description "MR – Digital multifunctional relays".

As relay input energizing quantities, three phase voltages should be applied to *MRN3* relay input circuits. Depending on the system conditions and the voltage transformer used, three voltages can be connected to the relay input circuits with either star or delta connection. In case of a star connection the phase-to-neutral voltage will be applied to the voltage input circuits, while the phase-to-phase voltages will be connected to the voltage input circuits in case of a delta connection. The voltage input connection must be set as a parameter, and should correspond with the actual voltage input connection:

Star connection:	Phase-to-neutral voltages will be measured and evaluated.
Delta connection:	Phase-to-phase voltages will be measured and evaluated.

6.4 Secondary injection test

6.4.1 Test equipment

- Voltmeter and frequency meter with class 1 or better,
- auxiliary power supply with the voltage corresponding to the rated data on the type plate,
- three-phase voltage supply unit with frequency regulation (Voltage: adjustable from 0 to 2 x U_N; Frequency: adjustable from 40 - 70 Hz),
- timer to measure the operating time (Accuracy class ±10 ms),
- switching device and
- Test leads and tools

6.5 Example of test circuit

For testing of the *MRN3* relay, a three phase voltage source with adjustable voltage and frequency is required. Figure 6.1 shows an example of a three-phase test circuit energizing the *MRN3* relay during test. The three phase voltages are applied to the relay in Y-connection.

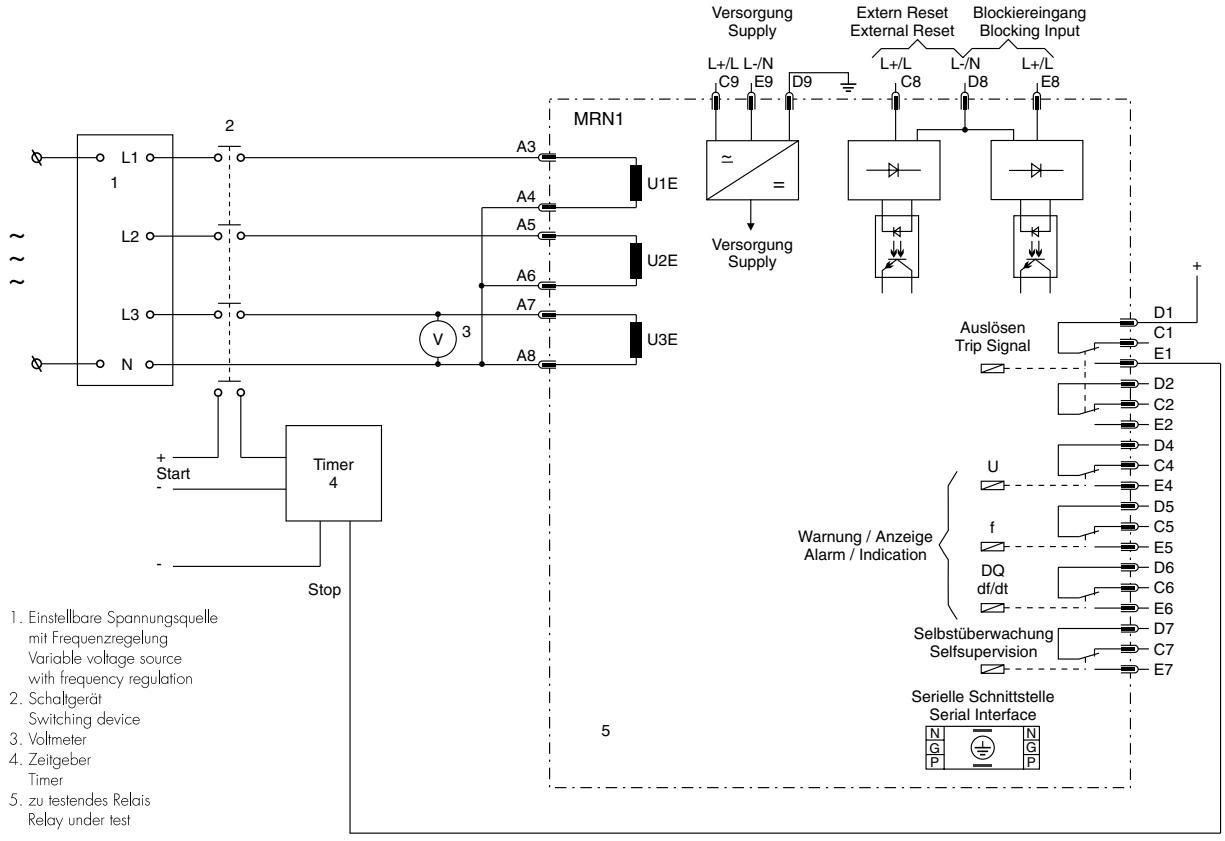


Figure 6.1: Test circuit

For testing the vector surge function of the relay, a test circuit which can produce phase angle change (vector surge) is required to simulate mains failures (please refer to chapter 6.5.6).

For testing the df/dt function of the relay, a special test equipment is required, which produces a constant rate of change of frequency.

6.5.1 Checking the input circuits and measuring functions

Apply three voltages of rated value to the voltage input circuits (terminals A3 - A8) of the relay. Check the measured voltages, frequency and vector surge on the display by pressing the push button <SELECT/RESET> repeatedly. The displayed measuring voltages (shown in Volt) are dependent on the wiring of the input voltage converters and the set transformation ratio.

The voltages are indicated on the display in volts.
At Y-connection:
- Phase-to-neutral voltages: LED L1, L2, L3

At Delta-connection:
- Phase-to-phase voltages: LED L1+L2, L2+L3, L3+L1

The frequency is indicated on the display in Hz: LED f (system frequency = 50.01Hz, Indication = 5001)
The vector surge is indicated on the display in degrees (for *MRN3-1*): LED $\Delta\Theta$ (Indication $\Delta\Theta$ in °)
The rate of change of frequency (LED df) is indicated on the display in Hz/s (for *MRN3-2*)

Change the voltages around the rated value and check the measured voltages on the display.
Change the system frequency around the rated frequency and check the measured frequency on the display.

Compare the voltage and frequency on display with the signal on voltmeter and frequency meter. The deviation for the voltage must not exceed 1% and for frequency <0.01 Hz.

By using an RMS-metering instrument, a greater deviation may be observed if the test voltage contains harmonics. Because the *MRN3* relay measures only the fundamental component of the input signals, the harmonics will be rejected by the internal DFFT-digital filter. Whereas the RMS-metering instrument measures the RMS-value of the input signals.

6.5.2 Checking the operating and reset ting values of the over/undervoltage functions

Note:
When the measuring voltage is connected or disconnected, vector surge tripping or df/dt tripping can occur. In order to ensure a trouble-free test procedure, the vector surge function or df/dt function of the relay have to be blocked before tests are started.

Apply three voltages with the rated value and gradually increase (decrease) the voltages until the relay starts, i.e. at the moment when the LED U> (or U<) lights up or the voltage alarm output relay (contact terminals D4/E4) is activated. Read the operating voltage indicated by the voltmeter. The deviation must not exceed 1% of the set operating value.

Furthermore, gradually decrease (increase) the voltages until the relay resets, i.e. the voltage alarm output relay is disengaged. Check that the dropout to pickup ratio for voltage is greater than 0.97 (for overvoltage function) or smaller than 1.03 (for undervoltage).

6.5.3 Checking the relay operating time of the over/undervoltage functions

To check the relay's operating time, a timer must be connected to the trip output relay contact (Contact terminals D1/E1). The timer should be started simultaneously with the voltage change from sound condition to a faulty condition and stopped by the trip relay contact. The operating time measured by timer should have a deviation about 3% of the set value or <20 ms.

6.5.4 Checking the operating and reset ting values of the over/underfrequency functions

Note:
Due to frequency changes, vector surge tripping or df/dt - tripping can occur during frequency tests. In order to ensure a trouble-free test procedure, the vector surge function or df/dt function of the relay have to be blocked before tests are started.
During frequency tests, each of the frequency elements should be tested separately. This makes it necessary that the other frequency elements of the relay have to be blocked by setting the frequency pickup values f_1 - f_3 to "EXIT". For testing the pickup and dropout to pickup values, the test frequency has to be increased (decreased) until the relay is engergized. This is indicated by lighting up of LEDs f_1 - f_3.
When comparing the values displayed with those of the frequency meter, the deviation must not exceed 0.01 Hz. The dropout to pickup values are ascertained by increasing (decreasing) the test frequency slowly until the output relay releases.
The dropout to pickup value for overfrequency must be >0.99, and for underfrequency <1.01.

6.5.5 Checking the relay operating time of the over/underfrequency functions

The operating time of the over/underfrequency functions can be tested in the similar manner as in chapter 6.5.3 for over/undervoltage functions.

6.5.6 Checking the vector surge function

With the help of an advanced relay test equipment a phase shift (vector surge) on the voltage signal can be obtained to test the vector surge function of *MRN3* relay. If there is no such testing facility available, a very simple simulation circuit may be used to test the vector surge function of the relay with a sufficient accuracy. Figure 6.2 shows the possibility to simulate a phase shift by means of a RC circuit. Closing or opening the switch S1 causes the phase angle of the input voltage to change depending on the adjustable resistor R.

The phase angle obtained may be calculated with the following formula and is almost independent on the test voltages.
In case of a 3-phase vector surge, the angle $\Delta\Theta$ can be calculated with the following formula if the parameters R_0, R and C are known:

$$\Delta\Theta = \text{arctg}\frac{1}{R_0 \cdot \omega \cdot C} - \text{arctg}\frac{1}{(R_0 + R) \cdot \omega \cdot C}$$

Example: R_0 = 1 Ohm, R = 363 Ohm, C = 3 µF

then: $\Delta\Theta \cong 19°$

Usually the voltage source impedance R_0 is negligible, hence R_0 may be assumed zero. Thus, the value of R may be calculated using the following simplified formula:

$$\Delta\Theta = 90° - \text{arctg}\ \frac{1}{R \cdot \omega \cdot C}$$

Note!
Using the above test circuit with single-phase vector surge, the resulting measured angle $\Delta\Theta$ is about half the value of $\Delta\Theta$ calculated for a 3-phase vector surge.
To make tripping possible during a one phase test procedure, the vector surge tripping has to be set to "1Ph".

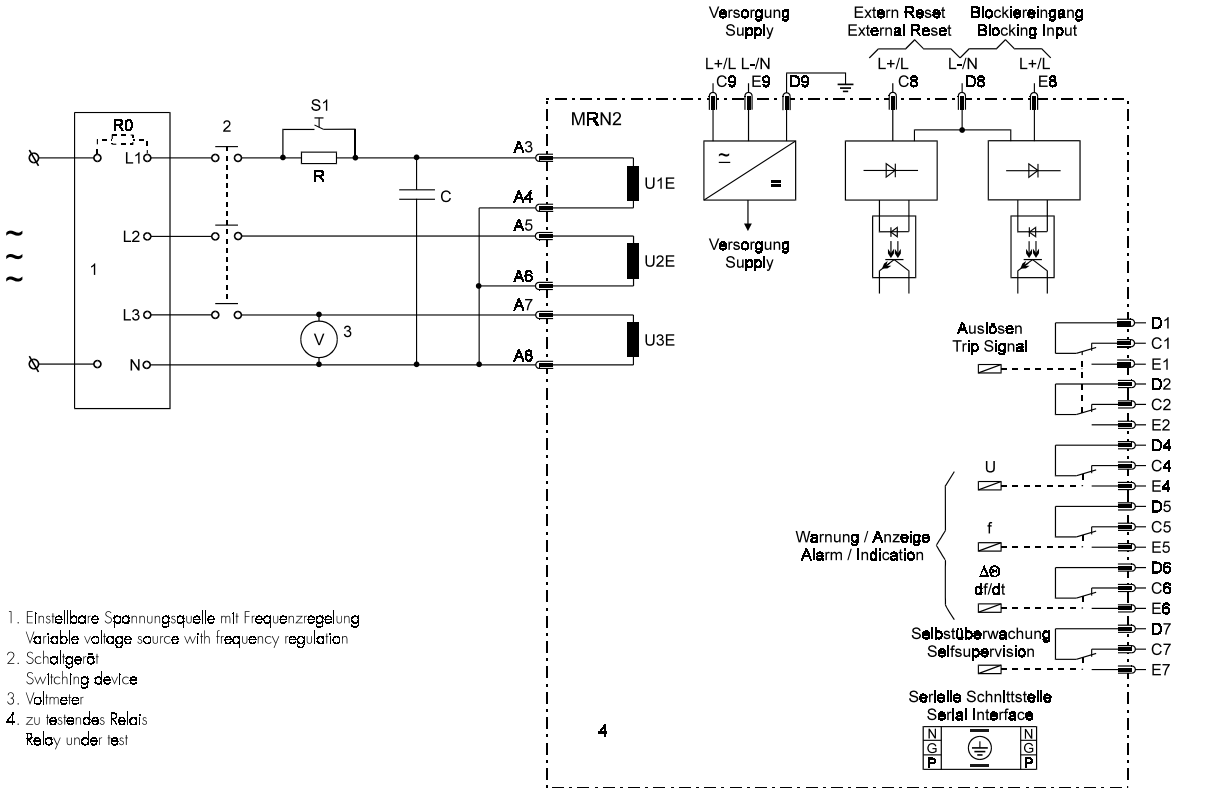

Figure 6.2: Test circuit for the vector surge function

6.5.7 Checking the external blocking and reset functions

The external blocking input is free programmable by the user.
To test the blocking function apply auxiliary supply voltage to the external blocking input of the relay (terminals E8/D8). Inject a test voltage which could cause tripping for the testes functions. Observe that there is no trip and alarm for those functions.

Remove the auxiliary supply voltage from the blocking input. Apply test voltages to trip the relay (message „TRIP" on the display). Return the test voltages to the sound condition and apply auxiliary supply voltage to the external reset input of the relay (terminals C8/D8). The display and LED indications should be reset immediately.

6.6 Primary injection test

Generally, a primary injection test could be carried out in the similar manner as the secondary injection test described above. With the difference that the protected power system should be, in this case, connected to the installed relays under test „on line", and the test voltages should be injected to the relay through the voltage transformers with the primary side energized. Since the cost and potential hazards are very high for such a test, primary injection tests are usually limited to very important protective relays in the power system.

Because of its powerful combined indicating and measuring functions, the *MRN3* relay may be tested in the manner of a primary injection test without extra expenditure and time consumption.

In actual service, for example, the measured voltage and frequency values on the *MRN3* relay display may be compared phase by phase with the concerned indications of the instruments of the switchboard to verify that the relay works and measures correctly.

6.7 Maintenance

Maintenance testing is generally done on site at regular intervals. These intervals vary among users depending on many factors: e.g. the type of protective relays employed; the importance of the primary equipment being protected; the user's past experience with the relay, etc.

For electromechanical or static relays, maintenance testing will be performed at least once a year according to the experiences. For digital relays like *MRN3*, this interval can be substantially longer. This is because:

- The *MRN3* relays are equipped with very wide self-supervision functions, so that many faults in the relay can be detected and signalised during service. Important: The self-supervision output relay must be connected to a central alarm panel!
- The combined measuring functions of *MRN3* relays enable supervision the relay functions during service.
- The combined TRIP test function of the *MRN3* relay allows to test the relay output circuits.

A testing interval of two years for maintenance will, therefore, be recommended.
During a maintenance test, the relay functions including the operating values and relay tripping times should be tested.

7 Technical data

7.1 Measuring input circuits

Rated data:	Nominal voltage U_N	100 V, 230 V, 400 V
	Nominal frequency f_N	40 - 70 Hz
Power consumption in voltage circuit:	<1 VA	
Thermal rating:	continuously	2 x U_N
Undervoltage lockout for frequency and vector surge measurement:	U< adjustable (5%...100% U_N)	

7.2 Common data

Dropout to pickup ratio:	for U>/U>> : >97%;	for U</U<< : <103%
	for f>/f>> : >99.98%;	for f</f<< : <100.02%
Dropout time:	60 ms	
Time lag error class index E:	±10 ms	
Minimum operating time:	40 ms	
Max. allowed interruption of the auxiliarxy supply without a facting the function of the device:	50 ms	
Influences on voltage measuring:		
Aux. voltage:	in the range 0.8 <U_H/U_{HN} <1.2 no additional influences to be measured	
Frequency:	in the range 0.8 <f / f_N <1.4 (for f_N = 50 Hz) <0.15% / Hz	
Harmonics:	up to 20% of the 3rd harmonic <0.1% per percent of the 3rd harmonic	
	up to 20% of the 5th harmonic <0.05% per percent of the 5th harmonic	
Influences on frequency measuring:		
Aux. voltage:	in the range <0.8 U_N/U_{HN} <1.2 no additional influences to be measured	
Frequency:	no influences	
Influences on delay time:	no additional influences to be measured	
GL-Approbation:	98776-96HH	
Bureau Veritas Approbation:	2650 6807 A00 H

Mobilgear® SHC XMP Series

Gear Oil

Product Description

Mobilgear SHC XMP Series supreme performance, fully synthetic industrial gear oils designed to provide optimum equipment protection and oil life even under extreme conditions. Mobil's polyalphaolefin (PAO) technology has been selected for its exceptional oxidation resistance and thermal properties, naturally high viscosity index, excellent low temperature fluidity and absence of undesirable compounds that are often found in mineral oils. The high viscosity index and low traction coefficient of this oil combine to provide a significant reduction in power consumption in many gear drives. Mobilgear SHC XMP Series lubricants contain an advanced and carefully blended proprietary additive system designed to provide excellent protection against conventional wear modes such as scuffing but also provides a high level of resistance against micropitting fatigue. In addition, compared to conventional gear oil chemistries, it offers the potential for improved lubrication of gearbox rolling element bearings. Mobilgear SHC XMP Series products offer outstanding rust and corrosion protection versus conventional gear oils, including seawater and acidic water protection. They show no tendency to plug fine filters even when wet and have excellent compatibility with ferrous and non-ferrous metals even at elevated temperatures.

Mobilgear SHC XMP lubricants are recommended for enclosed industrial gear drives including steel-on-steel spur, helical, and bevel gears. It is especially recommended for applications that may be subject to micropitting: especially heavily loaded gearboxes with surface-hardened tooth metallurgies. It may also be used in gear applications where extreme low and/or high temperatures are encountered and applications where corrosion may be severe.

Because of their unique mix of properties, including resistance to micropitting wear, and their performance in tough applications and wide temperature range, Mobilgear SHC XMP Series products enjoy a growing reputation among customers and OEMs around the world.

Features & Benefits

The Mobil brand lubricants designated as SHC is recognised and appreciated around the world for innovation and outstanding performance. These molecular design PAO synthetic products, pioneered by our research scientists, symbolise the continuing commitment to using advanced technology to provide outstanding products. A key factor in the development of Mobilgear SHC XMP Series was the close contacts between our scientists and application specialists with key OEMs to ensure that our product offerings will provide exceptional performance with the rapidly evolving industrial gear designs and operation.

Our work with equipment builders has helped confirm the results from our own laboratory tests showing the exceptional performance of the Mobilgear SHC XMP Series lubricants. Not least among the benefits shown in work with OEMs is the ability to resist micropitting wear which can occur with some highly loaded, case-hardened gearing applications. This cooperative work also demonstrated the all-round balanced performance benefits for the new Mobilgear SHC XMP technology, including a wide temperature range of application.

To address the issue of micropitting gear wear, our product formulation scientists designed a proprietary combination of additives which would resist traditional gear wear mechanisms as well as protecting against micropitting. Our formulators chose proprietary PAO synthetic base oils to provide exceptional oil life and deposit control and resistance to thermal/oxidative and chemical degradation, as well as the balance of the performance features. The wax-free nature of the synthetic base oil also provides low temperature fluidity characteristcs unmatched by mineral products and is a key benefit for remote, low ambient, applications. The Mobilgear SHC XMP Series lubricants offer the following benefits:

Features	Advantages and Potential Benefits
Superb protection from micropitting fatigue wear as well as high resistance to traditional scuffing wear	Extended gear and bearing life in enclosed gear drives operating under extreme conditions of load, speed and temperature
	Reduced unexpected downtime and less maintenance – especially critical for difficult to access gearboxes.
Excellent resistance to degradation at high temperatures	Extended oil life and drain intervals reduced oil consumption and manpower costs
Low traction PAO base stocks for improved gear efficiency	Reduced energy consumption and lower operating temperatures
High viscosity index base stocks reduce viscosity change with temperature	Ability to operate at both high and low temperatures: especially critical in remote applications with no oil heating or cooling
Excellent resistance to rust and corrosion and very good demulsibility	Smooth, trouble-free operation at high temperatures or in water-contaminated applications
	Excellent compatibility with soft metals
No filter plugging, even in presence of water	Less filter changes and reduced maintenance costs
Excellent compatibility with common gearbox materials of construction and with mineral-based gear oils	Easy changeover from mineral products

Applications

Application Considerations: While the Mobilgear SHC XMP Series are compatible with mineral oil based products, admixture may detract from their performance. Consequently it is recommended that before changing a system to one of the Mobilgear SHC XMP Series, it should be thoroughly cleaned out and flushed to achieve the maximum performance benefits.

Mobilgear SHC XMP Series supreme performance, fully synthetic industrial gear oils designed to provide optimum equipment protection and oil life even under extreme conditions. They are especially formulated to resist micropitting of modern, case hardened gearing and can operate in both high and low temperature environments. Typical applications include:

- Wind turbines, especially highly loaded and shock loaded units, remotely located units and extreme temperature environments
- Plastic extruder gearboxes
- Modern, highly loaded gearboxes used in the paper, steel, oil, textile, lumber and cement industries where gear protection and optimum oil life are required.

Specifications & Approvals

Posición aproximada del sensor en la parte trasera de la caja

Nota: La mirilla está fijada a la Caja por medio de tornillos M10, con 17mm de cabeza.

Anexo 37: Información sobre el sensor de flujo Hydac

Catálogo del sensor de flujo Hydac

Volver

Flow Rate Sensors

HYDAC Flow Rate Sensors are designed especially for use in hydraulic systems. Operation is based on turbine principle. Available with aluminium or stainless steel housing featuring thread connections for pressure and temperature sensors.

Products

EVS 3100
- material of housing: Aluminium (for mineral oil)
- range of viscosity 1...100 cSt (calibrated at 30 cSt)
- output signals 4...20 mA
- measuring ranges 1.2...20 l/min, 6...60 l/min, 15...300 l/min, 40...600 l/min. Further ranges on request

EVS 3110
- material of housing: Stainless steel (for water based fluids)
- range of viscosity 1...100 cSt (kalibriert bei 5 cSt)
- output signals 4...20 mA
- measuring ranges 1.2...20 l/min, 6...60 l/min, 15...300 l/min, 40...600 l/min. Further ranges on request

DATOS GENERALES PARA EL DISEÑO

Tipo de conductor : ACSR

Calibre	: 336.4 kCM
Cableado	: 26/2
Peso	: 0.687 kg/m
Diámetro	: 18.31 mm
Tensión de ruptura	: 6375 kg
Módulo Elasticidad	: 8000 kg/mm^2
Coef. Dilatac. Ter.	: 18.9x10^6 /ªC
Nombre	: Linnet

Hilo de Guarda : ACSR

Calibre	: 4/0
Cableado	: 6/1
Peso	: 0.433 kg/m
Nombre	: Penguin

Temperatura ambiente : 35 ºC

Temperatura máxima : 55 ºC

Estructuras : Postes de Madera

Tipo de poste	: Southern Yellow Pine
Clase del poste	: H2
Peso	: 2246 kg (4941 lb)
Fiber Stress	: 5.63 kg/mm^2 (8000 p.s.i.)
Carga de ruptura	: 2910kg (6400 lb)
Circunf. inferior	: 1.37 m (54 pulg, a 6 pies de la base)
Circunf. superior	: 0.79 m (31 pulg)
Tapper	: 20.83 mm/m (0.25 pulg/pie)
Fabricación	: ANSI 05.1

Aisladores de suspensión : Rígidos

Máxima carga cantiliver	: 1090 kg
Condic. normal operación	: 435 kg (40%)

Aisladores para ángulos y remates : ANSI C52-5 Tipo J

Altura	: 125 mm (5.75 pulg)
Diámetro	: 254 mm (10 pulg)
Peso	: 5.4 kg (12 lb)

Velocidad máx. Viento : 120 k/h

Factor de seguridad : 4 (Cuatro), Grado B del NESC

Ancho de la servidumbre : 10 m.

CRITERIOS BASICOS DE DISEÑO

La tensión de diseño del conductor es del 19% de la tensión de ruptura. Esta tensión es de 1210 kg.
La tensión de diseño del hilo guarda es del 25% de la tensión de ruptura. Esta tensión es de 950 kg.
Las condiciones inciales y finales de ambos conductores no deben sobrepasar el 30% de la tensión de ruptura (máximo), ni un 15% de esa tensión, como condición mínima.
Debido a que tanto los conductores como el hilo guarda son del tipo ACSR, se diseña para que la fecha máxima del hilo guarda sea tan solo el 80% de la fecha del conductor.
La distancia de claros mínimos debe ser de 7 metros.

CÁLCULO DEL VANO MAXIMO PERMITIDO (MAS, Maximum Allowable Span)

Para realizar el cálculo de los "vanos máximos permitidos" (MAS) se utilizaron los datos de diseño del punto 1 de esta memoria.
Se analizaron dos casos:

a) con una velocidad de viento de 160 km/h con un factor de seguridad de 1.

b) con velocidad de viento de 120 km/h pero con un factor de seguridad de 4.

Se utilizó una hoja electrónica diseñada para tales fines y que se muestra en el anexo 1.

De esta tabla se concluye, que para postes sin anclas el MAS es de 290 m. (caso a) y 275 m. (caso b). Por lo tanto se escoje el vano de 275 m como máximo.

LOCALIZACION DE SITIOS DE POSTE

La localización de los sitios de poste se realizó teniendo en cuenta el valor CVAL, dado por el programa de diseño, este valor se obtuvo para la condición de 55° C, sin viento y con tensiones finales (10 años creep).

La localización, de acuerdo a los planos de planta y perfil es como se muestra en la siguiente tabla, además se muestran los valores de las longitudes de los tramos de peso y viento (esto fue calculado para una tensión de diseño del 19 % de la tensión de ruptura del conductor):

Número Estructura	Angulo (°)	Estacionamiento (km)	Elevación (m.s.n.m)	Tramo de viento (m)	Tramo de peso (m)
1PR-10	0	0.000	682.0	91.7	433.5
2PS-10	0	0.180	647.0	205.1	79.1
3PA-10	8	0.405	619.4	199.25	225.5
4PA-10	21	0.575	596.0	114.25	328.9
5PA-10	12	0.630	581.7	176.8	-110.9
6PA-10	23	0.925	553.4	309.5	375.8
7PA-10	8	1.244	510.8	309.2	-51.9
8PA-10	2	1.539	531.9	202.6	286.6
9PA-10	5	1.648	534.5	120.9	355.8
10PS-10	0	1.780	520.0	171.6	69.9
11PA-10	7	1.990	509.1	185.9	314.3
12PA-10	8	2.150	489.1	121.8	203.5
13PA-10	15	2.231	475.2	181.3	-75.5
14PA-10	40	2.511	468.1	263.0	116.4
15PA-10	25	2.756	482.3	171.8	280.9
16PA-10	28	2.854	481.9	49.0	41.8

Se pueden separar las estructuras en cuatro tipos diferentes:

- Postes de suspensión, 2 en total (postes números 2 y 10)

- Postes con ángulos inferiores a 15°, 6 en total (postes números 3, 5, 7, 9, 11 y 12)

- Postes con ángulos superiores a 15° e inferiores a 30°, 6 en total (postes números 4, 5, 6, 13, 15 y 16)

- Postes de remate sea final o intermedio (postes números 1, 14 y XX)

Para cada uno de estos tipos de postes es necesario definir el tipo de vientos y anclas que tendrán

Se hizo una comprobación para los ángulos inferiores a los 15°, de forma tal que se conociera si era posible utilizar cadenas de suspensión o por el contrario aisladores rígidos. Para realizar esto se debe tomar encuenta: el peso de la cadena de aisladores, los tramos de peso y viento que afectan a cada uno de los casos.
Mediante este procedimiento se comprobó que las mencionadas estructuras deben tener aisladores rígidos.

VIENTOS Y ANCLAJES

Para realizar el cálculo de cables de los vientos se diseñaron hojas electrónicas que permiten, teniendo las tensiones para condiciones iniciales y finales, así como los vanos que afectan a los postes, deducir el calibre de los cables que se utilizarán
Los cálculos se realizaron para las presiones de viento generadas por vientos de 120 km/h y 160 km/h, el primero con un factor de seguridad de 4 y el segundo con factor de 1.
Estas hojas se realizaron para los postes de remate y ángulo.
De los cálculos realizados se deduce que el calibre de los cables para anclas es de 11.1 mm (7/16 de pulgada)
Aunque existen algunas anclas que podrían ser de un calibre inferior (9,5 mm, 3/8") es preferible "normalizar" el calibre hacia el cable superior.

Los anclajes que se utilizarán es del tipo "Cross Plate". este tipo de ancla tiene la ventaja de que no es necesaria una máquina para su instalación, además permite una capacidad de 30000 pulg-libra en suelos de clase 5

ATERRIZAMIENTOS

Se considera que para realizar los aterrizamientos de todos y cada uno de los postes, y para lograr al menos 10 ohmios de resistencia de puesta a tierra, las estructuras debe tener al menos dos varillas de puesta a tierra con una longitud de 3 m. y un diámetro de 16 mm.
Los detalles de estos aterrizamientos se muestran en la figura 4-5 para todos los casos.

Para el aterrizamiento de todas las estructuras se utilizan un cable de cobre sólido # 2, que sobresale 45 centímetros de la parte superior del poste, además el mismo cable se utiliza como bajante a través de todo el poste. En la parte inferior del poste se debe terminar el cable en forma de espiral. Los detalles se muestran en la figura Nº 8

CALCULO DE MATERIALES

Para realizar el cálculo de materiales también se diseñaron hojas electrónicas de forma que se pudieran calcular el total de materiales requeridos en forma sencilla.
Los materiales se calculan para los cuatro tipos de estructuras que tiene la línea de transmisión, es decir, remate, ángulo pequeño (menos de 15°), ángulos medianos (entre 15 y 30°) y para las dos estructuras de suspensión.
Al final de esta memoria se muestra la cantidad total de materiales que se deben adquirir.
Se recomienda una compra adicional de 15% o 10% en todos los items.

CONSTRUCCION DE LA LINEA

La norma a seguir para la construcción de la línea es el estándar T-805 A de la REA (Rural Electrification Administration) boletín 50-2

Para construir la línea se muestran las figuras Nº 4, 5, 6 y 7:

1. Para estructuras con ángulos entre 15º y 30º la figura principal es la Nº 4, los detalles se muestran en las figuras 4-1 hasta 4-6.

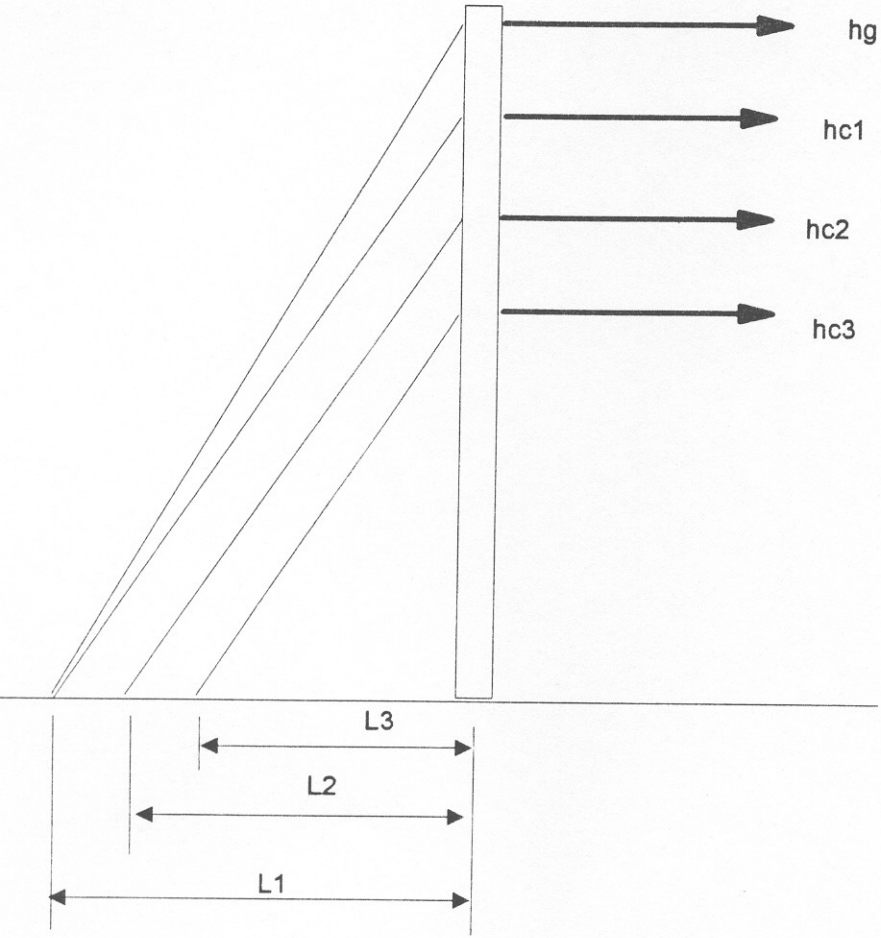
2. Para estructuras con ángulos entre 2º y 12º la figura principal es la Nº 5, los detalles se muestran en las figuras 5-1, 5-2 y 5-3, aquí se repiten algunos detalles comunes a las estructuras anteriores: figuras 4-3, 4-4 y 4-5.

3. Para estructuras de suspensión (tangenciales) se debe utilizar la figura Nº 6. Se muestran detalles en la figura 6-2.

4. Para estructuras de remate final o intermedio la figura correspondiente es la Nº 7. Los detalles se muestran en las figuras Nº 7-1 y Nº 7-2. Al igual que en casos anteriores se requieren otros ensambles para las anclas vientos y aterrizamiento: figuras Nº 4-3, Nº 4-4 y Nº 4-5.

Figura Nº 2

Localización de anclas, Postes de Remate



L3 = 35 pies (10.6 m)
L2 = 40.4 pies (12.2 m)
L1 = 45.3 pies (13,7 m)

LM is an international company with modern production facilities on the most important markets for wind energy.

The world's leading supplier of wind turbine rotor blades

LM Glasfiber A/S is the world's leading supplier of rotor blades for wind turbines. We offer a wide range of products that includes blades for all sizes of wind turbines from 250 kW to the biggest MW turbines, as well as the development of rotor blades for individual customers.

Today more than 40,000 LM rotor blades are in operation all over the world. This means that LM has accumulated the industry's most extensive knowledge bank on the production and operation of rotor blades. This knowledge, combined with decades of technological experience, is the foundation of our targeted research and development which is designed to optimise the energy production of rotor blades and ensure our customers reliability and optimum operation.

LM is always close to its customers with production and sales companies in Denmark, Germany, the Netherlands, Spain, the USA, India and China. This provides the basis for a project-oriented partnership in which, together with customers, we create the best possible solutions.

Some of the key words in connection with future utilisation of wind power are offshore wind farms and increasingly large wind turbines. LM has already gained valuable experience in these areas – so LM today is in full swing in designing wings for the wind turbines of the future.

PRINTED IN DENMARK/KREATIV SERVICE

LM Glasfiber A/S

The world's leading supplier of wind turbine rotor blades

A core competence of unique experience

LM Glasfiber A/S is the world's leading supplier of rotor blades for wind turbines. We have created this position through constantly focusing on quality and customer service and due to intensive, innovative research and product development in collaboration with our customers.

LM rotor blades are characterised by their high quality which is based on the company's extensive knowledge of composite materials and production technologies.

Our core competence is derived from a unique fund of experience in the fields of development, mould building, production and testing wind turbine rotor blades. Our knowledge bank is based on more than 40 years' product development using composite technology and the production of more than 40,000 rotor blades.

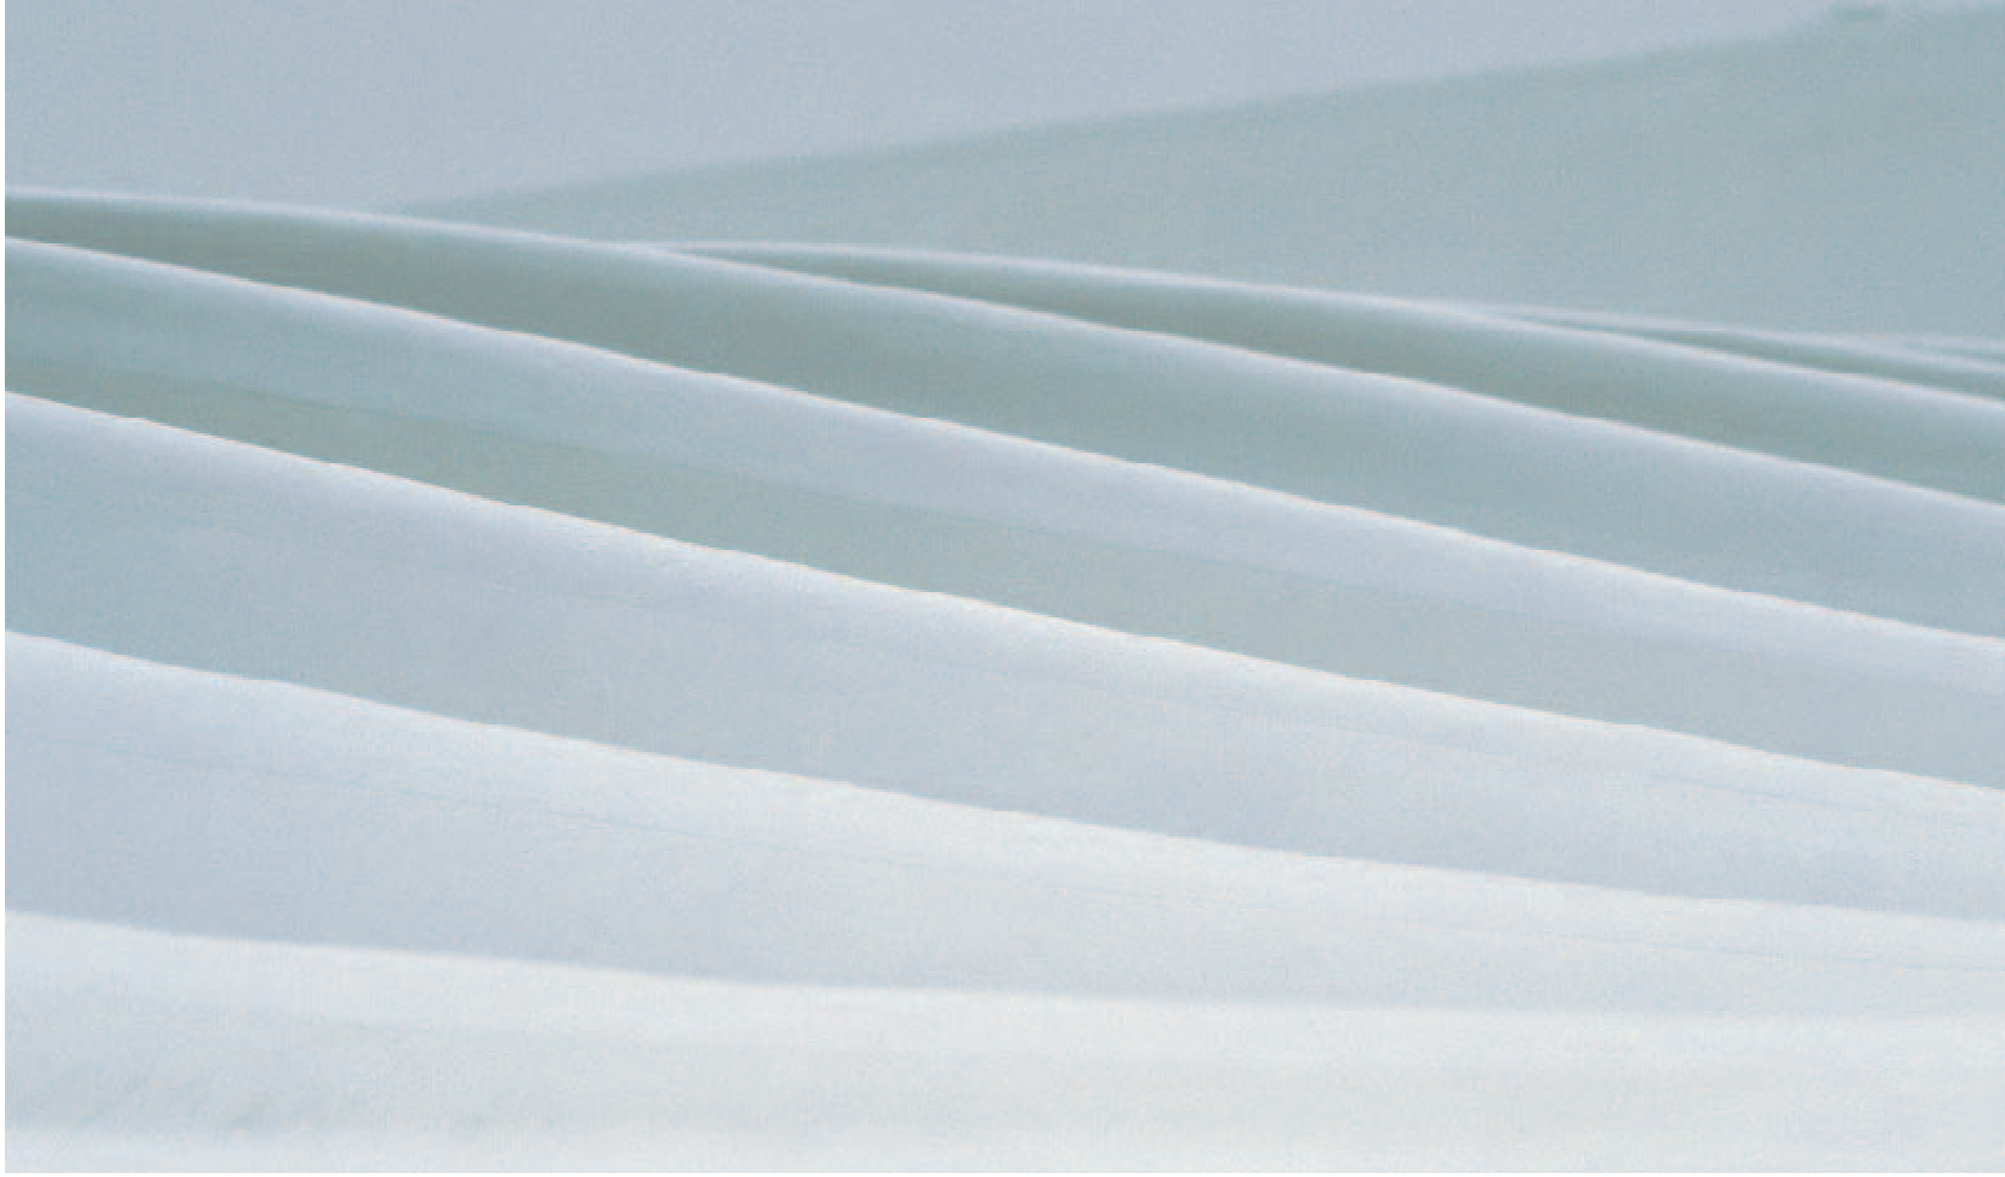
LM Glasfiber was among the pioneers when the development of modern wind turbines began. Today the company employs more than 2,000 people in Denmark, Germany, the Netherlands, Spain, the USA, India and China.

This global production, sales and service organisation ensures rapid, efficient deliveries accompanied by a high level of service, irrespective of where in the world the wind turbines will be erected. This provides our customers with security and quality, and LM Glasfiber with an excellent starting point to maintain its position as the world's leading supplier of rotor blades for wind turbines.

Decades of experience with technology and intensive development have provided LM with the ability necessary to supply rotor blades for wind turbines from 250 kW to the largest MW turbines.

A wide range of products

A rotor blade for all wind turbines



LM's experience and capacity create the background for a comprehensive series production of large rotor blades for MW wind turbines.

LM Glasfiber has a comprehensive range of products comprising more than 30 different types of rotor blades which vary in length from 12 metres to way in excess of three times this length. This makes it possible for us to offer rotor blades for all sizes of wind turbines, from the smaller 250 kW to the biggest, most advanced MW wind turbines for offshore use. Our product range includes blades for pitch, stall and active stall regulation, as well as for wind turbines that run at a constant or variable speed of rotation.

Our various products are suitable for all erection sites – no matter whether these are high or low wind areas. No matter whether erection is carried out under demanding climatic conditions in arctic or tropical surroundings. And LM has also developed rotor blades for offshore wind turbines where the corrosive marine environment and the demand for minimum maintenance weigh heavily in the balance.

We can meet our customers' wishes on the basis of our standard range, where the individual blades can be customised. But we can also supply blades developed especially for the individual customer.

All rotor blades that leave LM's factories are made to customers' specifications irrespective of whether these are blades from our standard range or were specially developed for the individual customers.

Our targeted product development ensures that LM will also be able to supply the rotor blades required by our customers in the future.

The aerodynamic efficiency of rotor blades can be increased with the help of LM Vortex Generators, while the high-strength steel root construction and the lightning protection of the blades offer maximun safety.

LM's rotor blades are recognised for their high quality which is systematically laid down throughout all stages of the process – from development, mould building, production and testing to delivery and service. Quality comes to expression in the long lifetime of the blades, reliable operation and high yields – but also in their simple maintenance requirements.

The lifetime of the rotor blades is founded on a thoroughly considered choice of materials. In addition a high level of safety is achieved thanks to a series of effective features such as LM's familiar, well-tested root construction, tip brake, vibration damping and lightning protection.

The aerodynamic efficiency of the rotor blade can be optimised to suit the individual wind turbine and wind conditions at the site. This is brought about with the help of various LM accessories which include our Vortex Generators that can improve the wind turbine's energy production by up to 4-6 percent.

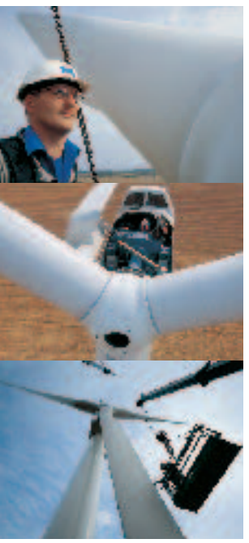
LM rotor blades harmonise with nature. An intensive development programme has reduced blade noise by more than 50 percent and made LM rotor blades some of the most comparatively noiseless blades in the world, while the extremely matt surfaces of the rotor blades minimise reflection. But developments do not stop at this. Our targeted product development is a guarantee that we will also be able to supply the blades that customers want in the future. Irrespective of demands on size and specific features.

Rotor blades are subjected to demanding tests on LM's test-beds with physical loads that correspond to more than 20 years' operation.

More than 40,000 LM rotor blades in operation

Quality ensures security and optimum operation

The LM SafeGuard® service concept provides systematic inspection of LM rotor blades. This prevents damage and increases the lifetime of the blades.



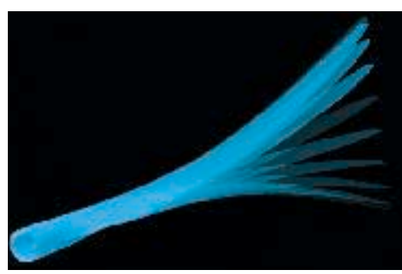
A wind turbine is a major investment. It must function to the optimum – at all times and throughout its lifetime. With more than 20 years' experience of manufacturing rotor blades LM Glasfiber possesses the competence and the capacity to guarantee high quality series production for our customers. Our quality assurance system is certified in compliance with ISO 9001 by Det Norske Veritas, and blades are tested and approved in accordance with the industry's most exacting guidelines in collaboration with Risø National Laboratory, Det Norske Veritas and Germanischer Lloyd.

LM has carried out static and dynamic full-scale tests on a very large number of rotor blades over the past 20 years. This comprehensive programme has led to the acquisition of valuable knowledge which is utilised today in the design and construction of new rotor blades.
This process includes extensive aeroelastic calculations and simulations of the loads rotor blades are exposed to under the most extreme conditions over a lifetime of 20 years. Prototypes are constructed on the basis of these calculations and tested with physical loads that correspond to 20 years' operation. This has allowed us to make ongoing improvements in the materials used, blade construction and production processes, and LM rotor blades are therefore characterised by great strength, excellent fatigue properties and a high level of safety. Facts documented by the experience gained from the more than 40,000 blades in operation.

A good starting point should be maintained. This is why we have developed LM SafeGuard® – a complete service concept designed to ensure the trouble-free operation and maintenance of rotor blades throughout their lifetime. Damage that could lead to expensive repairs and interrupted operation can be avoided with the help of systematic preventive maintenance inspection.

LM SafeGuard® means that the warranty period for rotor blades can be extended from two years up to ten years. This provides wind turbine owners with the maximum reliability for trouble-free operation and financial security.

Comprehensive calculations and simulations of 20 years' operation precede the design and testing of new prototypes.



LM's extensive capacity and competence in research and development are utilised in the design and construction of the new generation of large rotor blades.

Goal-oriented research and development

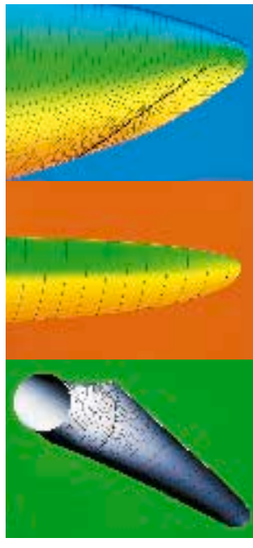
We optimise rotor blade energy production

Rotor blades are a wind turbine's engine. LM Glasfiber therefore constantly focuses on optimising their energy production for the purpose of reducing the price of the electricity produced with the help of wind power as much as possible.

For decades LM has been in the lead when it comes to developing rotor blades. This is due to the fact that we have carried out comprehensive research and development programmes in such areas as aerodynamics, blade construction, materials and production processes.

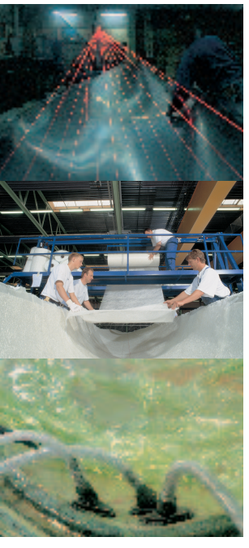
Programmes which range from the development of new profiles, which pave the way for lighter, less expensive blades, to the construction of the huge wind turbine rotor blades of the future for offshore use. In addition to this we make a continuous effort to optimise such areas as blade noise reduction, vibration damping, aerodynamics, de-icing and lightning protection. The results are solutions and technologies that improve the efficiency of the rotor blades and create the foundation for the longest possible lifetime for both wind turbines and blades.

Intensive research and development put LM rotor blades in the lead in such areas as aerodynamics and design.



Advanced development facilities are combined with precision craftsmanship in the design and construction of blade moulds and production tools.

The quality of LM rotor blades is laid down through all phases of the process, from design and construction to mould building and series production.



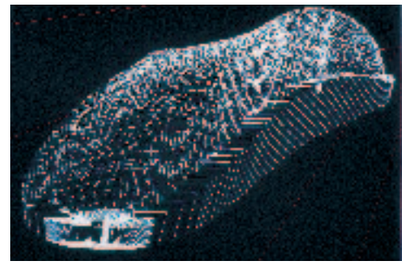
Intensive material and process development is carried out at LM's R&D laboratory in close collaboration with suppliers and institutes of technology. The knowledge derived from these efforts will help to extend the limits of what is possible in modern rotor blade construction in the future. As a result of this LM now exclusively develops rotor blades for series production using vacuum infusion technology. This provides better, more uniform product quality and greatly improves the working environment.

LM's research and development is based on advanced analysis and design tools. Some of these tools now constitute a valuable bridge between blade construction, mould building and blade testing. This offers our customers the advantage of shorter development times, high precision and reliability.

A targeted development effort has increased the efficiency of wind turbines year after year. This development will continue with the ongoing optimisation of rotor blades, wind turbine controls, gears and generators – individually in a necessary interaction. This is the reason why we carry out our development programmes on an international basis in close collaboration with our customers and a series of institutes of technology, universities and knowledge centres.

This is the only way we can continue to make wind power an increasingly competitive source of energy – for the benefit of our customers and the environment.

Advanced analysis and calculation tools used in design and construction ensure our customers rapid, effective development of new rotor blades.



LM has accumulated a unique fund of knowledge and experience based on a total production of more than 40,000 rotor blades.

The industry's most comprehensive knowledge bank

Building the future on decades of experience

Experience is a necessary foundation for the ability to develop and manufacture quality products. The production of more than 40,000 rotor blades has provided LM Glasfiber with a unique fund of knowledge and experience in connection with all aspects of rotor blade construction. Everything from design, choice of materials, mould building, the pro-duction of prototypes and testing, to series production, shipping, handling in connection with rotor blade installation, and service.
A corresponding knowledge bank has been built up around the performance of rotor blades. LM blades are in trouble-free operation in most parts of the world in highly varying climates, which range from arctic to tropical wind and weather conditions.

LM began working with fibre glass as early as 1953 utilising the material's many properties and areas of use. This meant that LM had accumulated a considerable amount of knowledge on fibre glass when, as one of the pioneers, the company started manufacturing rotor blades for wind turbines at the end of the 1970s.

Product and process development have been in focus at LM Glasfiber ever since. The consequence of this is that the company today possesses a detailed knowledge and great experience of production technology in connection with composite materials and their use.

Knowledge and experience that point directly to the future.

The finish and uniformly high quality of LM rotor blades are founded on decades of targeted research into composite materials and their many uses.

Wind turbine projects are becoming increasingly extensive heightening the demands on business partners.

A project-oriented partnership

Creating the best solution – together

LM Glasfiber not only manufactures rotor blades. We develop and manufacture a fifth part of a wind turbine in a close partnership with our customers. A project-oriented collaboration whose goal is to produce the best solution.

By working together with LM, customers gain access to the industry's most extensive knowledge bank in connection with rotor blade technology. This makes us an attractive business partner and adviser capable of participating actively at all stages of the process from the initial preparation of technical specifications to the securing of type approval and erecting the wind turbine.

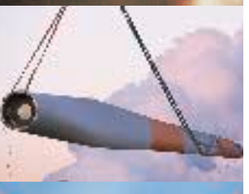
The significance of having the right business partners is growing in step with the increasing size and complexity of wind turbine projects. This heightens the demands on business and development partners.

LM is a well-consolidated company with a comprehensive development and production capacity. Our own mould building facilities and test-beds mean that our customers can reap the benefits of more rapid rotor blade construction and the flexible adaptation of our production capacity.

LM's comprehensive competence and capacity in the fields of research and production ensure our customers an efficient development process and reliable deliveries.

LM has the ability to carry the weight of development projects originating in customers' requirements for increasingly large rotor blades.

Our experience ensures efficient management and drive in wind turbine projects and we can play an active role at all stages - from concept development to the erection of wind turbines.



Our goal-oriented, long-term investment strategy ensures that our company will remain at the forefront of developments in the future. We are therefore capable of performing the comprehensive development projects that arise from the need for increasingly large rotor blades for megawatt wind turbines and offshore wind farms.

Many years' participation in development projects have given us the necessary experience to ensure effective project management and drive. Our customers can therefore rely on us to carry out even the most extensive, complex projects within the agreed time.

LM manufactures customer specific blades as well as customer modified standard blades. Our close collaboration with customers is therefore both important and relevant – because wind turbine design and rotor blade design are closely connected.

Irrespective of the nature of the project a solution is arrived at through a close, constructive collaboration between the customer and LM. This ensures high quality and subsequent satisfaction – also for the wind turbine owner, who must benefit from his investment for more than 20 years.

Our international organisation provides our customers with advantages regarding economy and logistics, in addition to professional service, no matter where in the world the rotor blades are supplied.

Global production and service

LM is always close to its customers

LM Glasfiber is an international company with production facilities located at the most important markets for wind power. This provides our customers with a financial advantage as well as reliable deliveries and service.

Being close to the market means that we can act effectively and flexibly.
In many cases we can utilise the group's international capacity to manufacture rotor blades in those places they are in demand. This ensures optimum logistics for our customers and reduces the cost of transport.

In addition LM's international organisation makes it possible for us to offer professional, global service. Irrespective of where in the world the rotor blades are to be delivered, or the wind turbines erected.

LM's position on the world market was established in the 1980s. Since then we have acquired market shares all over the world and today LM's rotor blades are turning on all continents. Our headquarters at Lunderskov, Denmark, co-ordinates activities in the production and sales companies in Denmark, Germany, the Netherlands, Spain, the USA, India and China. In total the group has in excess of 150,000 m^2 of premises at its disposal and employs more than 2,000 people world-wide.

LM's global production and service are founded on a comprehensive transfer of technology and a quality assurance system certified in accordance with ISO 9002. This means that our customers can rely on a uniformly high level of quality – no matter where in the world our rotor blades are manufactured or delivered.

LM's position on the global market was established in the 1980s. Today LM rotor blades are turning on every continent.

Focus on large wind turbines and offshore wind farms

LM designs the rotor blades for tomorrow's wind turbines

LM possesses the industry's most comprehensive offshore experience in the field of rotor blade technology.

The wind energy produced in the future will be characterised by increasingly bigger and more cost effective wind turbines and huge offshore wind farms. LM Glasfiber has worked purposefully to meet the challenges that these developments present.

LM can offer the market's biggest commercial rotor blades in the form of series production and we have the industry's greatest offshore experience in the field of blade technology. In this connection LM rotor blades were used at the Danish offshore wind farm at Vindeby off the island of Lolland, at the Swedish Bockstigen offshore wind farm near Gotland and the wind farm at Ijselmeer in the Netherlands.

The offshore based wind farms of the future will be even bigger and will include all the challenges of wind power. These wind turbines will require the development of increasingly large rotor blades adapted to the special offshore conditions in order to continue increasing yields and the lifetime of the blades. Servicing offshore wind turbine rotor blades is very expensive. The goal is therefore for the blades to be able to stand up to the corrosive marine environment without ongoing maintenance, just as the blades LM has supplied for the existing offshore wind turbines can.

LM Glasfiber will continue at the forefront of international wind turbine technology in the future. We wish to extend the limits of what is possible in modern rotor blade construction. On the basis of our experience, resources and capacity, and in close collaboration with wind turbine manufacturers, we will help to ensure that it will be possible to reduce the price of electricity produced with the help of wind power on an ongoing basis. For the benefit of the utilisation of wind power. For the benefit of the environment. And for the benefit of our customers.

GENERAL DATA FOR ROTOR BLADE TYPE: LM 19.1

Dimensions:

Blade length	l	:	19037	mm	± 20 mm
Max. root chord	Croot	:	1650	mm	± 20 mm
Tip chord	Ctip	:	70	mm	± 10 mm
Blade area	A	:	21.9	m²	
Twist		:	20.0	°	± 0.5 °
Airfoil section		:	FFA-W3, NACA 634		
Natural frequency flapwise		:	1.74	Hz	
Natural frequency edgewise		:	3.16	Hz	
Blade weight	m	:	1960	kg	± 50 kg
Momentum of inertia per blade (rotor D=41.0 m)		:	144000	kgm²	
C of G distance from rootbase	C.o.G.	:	6000	mm	

Direction of rotation (downwind)	:	Clockwise
Selfstarting	:	Yes

Installation dimensions:

Root flange outside diameter	Du	:	1075	mm	
Bolt circle diameter	BCD	:	1000	mm	± 1 mm
Number of bolts	n	:	40		
Bolt size	M	:	24	mm	
1st hole of BCD rel. to tip chord seen from tip	clockwise	:	4.5	°	± 0.5 °
Tip to tower distance (min.)		:	2160	mm	

GRP/steel connection:

Embedded high strength steel bolts, with internal M24 threads.

Aerodynamic brake:

Type	:	Tipspoiler	
Length	:	2687 mm	± 10 mm
Movement	approx :	74°	
Activation	:	Hydraulic cylinder placed near root flange (included from factory)	
Weight	:	70 kg	+4 / -3 kg
Center of Gravity for tip weight	:	2255 mm	± 50 mm from tip
With standard LM lightning conductor:			
Weight	:	74.5 kg	+4 / -3 kg
C.o.G. for tip weight	:	2170 mm	± 50 mm from tip

Materials used:

Skin, spar and root	:	Fibre glass/polyester
Embedded bolts for mounting	:	Crome steel alloy
Spoiler mechanism	:	Stainless steel / Carbonfibre-epoxy

LM Glasfiber A/S reserves the right to amend specifications without further notice.

GENERAL OPERATIONAL LIMITS FOR ROTOR BLADE TYPE: LM 19.1

Rotor configuration:

Number of blades in rotor	i	:	3	
Placement of rotor		:	upwind	
Power control		:	stall	
Yaw system		:	forced	
Hub design		:	rigid	

Operational limits: (max. values)

Rotor diameter	D	:	44	m	
Number of revolutions (operation)	no	:	30.00	rpm	
Tip speed (operation)	Vtip	:	62.00	m/s	
Generator power	Pel	:	750	kW	1)
Yaw error (operation)	sw	:	20	°	2)
Cut out wind	Vo	:	25	m/s	1)
Survival wind	Ve	:	70	m/s	3)
Tipspeed for release of tipspoiler	nc	:	1.3 · Vtip		
Brake torque (nominal on rotor shaft)	Mbr	:	711	kNm	
Brake torque (emergency)	Mbr,e	:	948	kNm	

Time for activation of tipspoiler : $0.8 < t$ sec. 4)

Min hydraulic retaining pressure = calculated pressure at 15% overspeed for the heaviest tip in a set. For calculations please ask LM.
Eg. D=44m, n=26,9rpm, Vtip=62m/s, Hydraulic cylinder ø60/30mm, Tip weight=78,5 kg with standard LM lightning conductor.
Retaining pressure = 91,6 Bar.

Operation temperature	:	Min. -20° C.- Max. 55° C. OAT (Outside Ambient Temperature). Min. -30° C. Optional Otherwise ask the manufacturer.
Mounting	:	Min. and Max. requirements are laid down in the Installation and Maintenance Manual.
Operation under icing conditions	:	Under extreme climatic conditions where icing has added an unbalance, the operation must stop until a de-icing has taken place.

All wind speeds stated are measured in hub height.

1) 10 min. mean values.
2) At a max. yaw error of 20° is understood:The angle between the wind direction and the axis of the turbine systematically has a mean value greater than 20°.
3) 2 sec. mean value.
4) The hydraulic system must be dampened in order to prevent damage on the tip mechanism, from inertia forces on the tipspoiler.

LM Glasfiber A/S reserves the right to amend specifications without further notice.

23.06.98/MM

DESCRIPTION.

The LM 19.1 blade is built as a self-supporting structure comprising of two skin-halves mounted round two main webs going from root end to tip.

Bushings with internal thread are embedded in the root section, and so forming the attachment to the hub. This root-to-hub-mounting-principle has been extensively tested at the Aarhus Institute of Technology where basicly the fatique properties were evaluated.

Shells, spars and root section are made of fibre-glass reinforced polyester, where the main strength properties have been achieved by using continuous fibres (Unidirectional Rowings). The bushings are made of chrome alloy steel. All metal parts for the aerodynamic blade tip brake are made of stainless steel and carbon fiber/epoxy.

The aerodynamic tip brake consists of the outer 2687 mm of the blade, mounted on a carbon/epoxy shaft.

During operation of the turbine, the tip is kept in place by a hydraulic cylinder placed near the root flange, and connected with the tip through a stainless steel wire. By activation of the tip brake, the hydraulic pressure is released, and the centrifugal forces on the tip are used to obtain an axial displacement of the tip and the shaft of approx. 180 mm.

During the displacement the tip is forced to turn app. 74° by a tooted wheel with diagonally teeth. The hydraulic cylinder is throttled, so the deployment of the tip is dampened in order to protect the tip mechanism against damage, due to inertial forces in the moving parts.

The profile chosen FFA-W3 and NACA 634 series has proven highly productive and show little sensitivity to dirt. Also its stalling properties are fine.

Each blade of a set is balanced to have the same weight in the root as well as in the tip as the two other blades of the set. A record is kept of this momentum in order to make a replacement easier in case of damage occurring during transport or installation.

The production takes place according to the quality system of LM Glasfiber A/S that meets the requirements of ISO 9001.

Further to this in connection with the production surveillance by for instance the Germanischer Lloyd or Det Norske Veritas, a "product certificate of conformity" can be issued.

The blade is calculated for normal security class acc. to Danish standards.

<u>Standard LM Lightning Conducting system - General Description.</u>

The lightning conducting system is built as an internal system, which in a controlled way is capable of conducting the lightning current from the tip of the blade to the root flange.

The system is developed in the light of extensive statistic material, showing where LM blades are struck by lightning along with laboratory tests where lightning currents have been simulated into the main components. Furthermore field tests on blades struck by lightning, confirmed the capability of the system to conduct lightning current.

The lightning conducting system consists of a capture part, where the visual parts "the so -called lightning receptors" are placed outermost on the tip. Lightning receptors are connected to the root flange via the internal lightning conducting components.

The lightning conducting system contains two parts, which depending on the lightning frequency, may be considered as wearing parts. Replacement of these parts are described under the section: Servicing of Standard LM Lightning Conducting System.

04.06.97.
FML

FUNCTIONAL DESCRIPTION

Hydraulic airbrake mechanism (drawing No. 023200) (drawing No. 025500 with LM lightning protection)

Design:

1. The shaft (008705) being embedded in the main structure of the tip carries at the opposite end an epoxyglued spline. This spline connects to wire (229501) through an eye screw - part No. 126601.

   The wire leads to the rootend through a PVC tube (009501) and connects to the hydraulic cylinder (127901) through a rigging screw.

   The tip is aligned to the blade by means of 2 nylon cones (064801), guiding into 2 female cones embedded in the tip bulkhead.

   The tip movement while being activated is controlled by a guideblock (internal threaded) (126201).

   The coil spring (128401) secures that the guideblock performs an axial movement of about 26 mm to clear the nylon cones prior to initiate the pivoting movement.

   The coil spring (128701) assures that the tip stays deployed during slow rotation.

   By dismantling inspection cover (079804) and lid (126901) the guide block (126201), the mail spring, the eye screw (126601), the wire inclusive of its forked terminal as well as the small coil spring (128401) become accessible.

Function:

2. During normal operation the tip will be aligned and held firm to the blade as a result of the hydraulic line pressure acting on the cylinder.

   In an overspeed situation the centrifugal forces acting on the cylinder through the stainless steel wire create an increase in the hydralic line pressure. A pilotguided pressure valve registers this increased line pressure and opens up at a predetermined pressure level.

   As the hydraulic system becomes depressurized, the tip brake becomes activated. The actual movement of the tip amounts to 180 ± 4 mm, with the pivoting movement being approx. 74° nose-up.

   The movement must be damped through a throttling of the oil flow. This is accomplished through the mounting of an orifice in the cylinder outlet.

Resetting of the tip:

3. Under normal operation, the tip is being reset by supplying the hydraulic system its normal pressure.

   The rotor has to be stopped, before resetting the tip.

   By normal stop the system must be made thus it automatically resets the blade tip when the rotor stops, and in this situation it shall remain with so much hydraulic pressure that it at least keeps the blade tips fixed in closed position.

22.04.98
TM

INSTALLATION.

Prior to installation, note the blade numbers for reference purpose (these are embedded in the cylindrical surface close to the root and on a label to be found on the root flange).

I. The condition of the surface:

The gelcoat surface has to be clean and smooth without scratches. Scratches, if any, are spot painted. If the spoiler is covered with tape (to prevent foreign particles from entering the brake while in transit), remove it.

Glue from the tape if any must be removed. Please be sure that the wax film is intact.

II Opening and closing of the air brake for inspection purposes:

a. When the tape has been removed from the tip cutting and there is no pressure on the hydraulic system, the tip brake will open itself due to the built in spring device.

Check that the suspension of the hydraulic cylinder on the root end is intact and without any wryness due to transport or other handling.

Check all visible mechanical joints.

Check the attachment of the wire to the piston rod of the hydraulic cylinder.

The surface of the piston rod has to be intact.

b. General inspections

The hydraulic system is checked visually for leaks at the gasket, bleading valve and connection.

c. Airing of the hydraulic system

It is of great importance that carefull airing is carried out followed by refilling with hydraulic fluid, prior to operating the generator.

Remember that the blade-(and with that the hydraulic pipe), while airing, must be positioned in such a way that air can escape from the system.

With air in the hydraulic an uncontrolled release of the air brake could take place, which might have a destructive effect on the attachments of the flap.

The airing is done one blade at a time by purching oil until air stops coming out of the air relief valve on the cylinder barrel.
To ensure that a ventilated blade is not sucking air into the system, while the other blade are ventilated, it is recommended that each hydraulic line is separated, while the airing takes place.

06.05.96
TM

IMPORTANT !!!

As long as the hydraulic system has not been filled and bleading has been completed, the rotor has to be stopped.

III Attachment of the blade to the hub:

Make sure that the blade root flange lays flat onto the hub.

The load on the bolts must be dispersed even.

The bolts for mounting must be new and of quality ISO class 8.8.
The free length of the bolt must be Min. 100 mm (4 x bolt diameter). All sliding surfaces of the bolt must be greased with Molybdenum disulphide or similar. Torqueing moment according to DS 412.

If the hub is made of cast steel, a bushing (washer) with a large supporting surface must be incorporated between bolthead and steel casting.

IV. Pitching:

The pitch angle is stated by the turbine manufacturer (depending on the location of the turbine, rotor diameter, RPM and max. power output).

The tip chord is marked on the root flange and further more assisted with a logging scale.

The accuracy adjustment for the 3 blades of the turbine in mutual ought to be within 1/2°.

V. Check plane of rotation:

Checking the plane of rotation is done by measuring the distance from the tip of the blade to the tower. The measurement must be carried out on all 3 blades at the same spot on the tower.

The mutual distance between the blades may only vary +/- 50 mm.

VI. Requirements on hub rigidity:

Please note that the natural frequency of the fitted blade will be influenced if the hub is not in possession of sufficient rigidity.

17.11.92
KB/

MOUNTING OF TIP AND CYLINDER:

By remounting of tip and/or hydraulic cylinder of your rotor blades use the procedure described below:

Mounting of tip (ref. drawing No. 023200): (drawing No. 025500 with LM lightning protection)

- In the guide house for the pivoting of the tip movement mount the coil spring (#128401) and plastic guide block (#126201) with inside spline, in such a way that the mark indication of the 1. tooth of the spline is pointing upwards and towards the root end.

- Guide the spline end of the carbon-fibre shaft (#008705) into the guide block (#126201) in such a way that the tip meets the mainblock parallelly in normal position.

- The 1¼" pipe threads on the eye screw and in the spline are inspected for damage and impurities. After a thorough cleaning of the threads, they are greased with "Metallfreie Montagepasta TC 575 # 175016".

- Position the forked stop collar (#126301) on the eye screw (#126601), which afterwards is screwed lightly into the spline (#008705). Then tighten eye screw (#126601).

- Pointed screw (#001993) on spline (#008705) is to be tightened.

- Setscrew (#020003) on Cover (#126901) and screw (#033803) on inspection cover (#079804) is to be tightened.

Mounting of hydraulic cylinder (ref. drawing No. 023200): (drawing No. 025500 with LM lightning protection)

- 2 ea supports for cylinder (#110501) is to be mounted on the flange (#114201) by means of setscrews M12 x 50 mm (#007903) and selflocking nuts (#002243).

- 2 ea electrical insulating bushings (#124301) to be mounted in the hydraulic cylinder (#127901).

- Hydraulic cylinder (#127901), completely premounted, is to be placed in the supports (#110501), and to be mounted with a transverse bolt (#111501), 2 ea washers (#002363) and 2 ea splits (#002083).

- Connect wire to the cylinder by means of bolt.

Adjusting of tip during mounting:

- Mount the rigging screw on to the wire and the hydraulic cylinder (#127901), tighten rigging screw so that the distance between tip and blade in open position is 180 ± 4 [mm].

PTO

MAINTENANCE

After some time of use, it is inevitable that a border will be shaped on the front edge of the blade, consisting of insects and dirt.

This border might have a negative influence on the effect of the blades, and if it is requested to be removed, the following instruction can be recommended:

1. The blades are waxed with Yacht Cleaner which is a highly concent rated cleansing agent without grinding mediums, based on water, that can be thinned with water.

2. Hereafter Yacht Polish is used which is a wax fluid with grinding mediums. This polish cleans and polishes in 1 (one) working operation. For extreme difficult spots and rooted dirt, Yacht Rubbing can be used.

3. To obtain the best possible result of this treatment, it is recommended to finish off with Yacht Wax, which is a wax fluid without grinding mediums. This wax protects and preserves the blade.

You may be content with only giving Yacht Wax on the front edge of the blade.

All the abovementioned products are of the make **International Farvefabrik A/S, Knud Bro Allé 10, DK-3600 Stenlase.**

We draw your attention to the fact, that the instructions on the labels are followed.

If there are scratches, rust extracts on the root flange etc. these have to be repaired.

If it is necessary to repair damages on the surface of the blades, please follow the instructions given in the enclosed Guidance to Repair of Fibreglass-reinforced Polyester.

We congratulate you on your LM rotor blades - in case you have further questions you are always welcome to contact us.

SERVICING OF THE HYDRAULIC TIPSPOILER OF THE LM 19.1 BLADE.

3½ months service inspection:

1. Check that the tip is totally closed during normal operational RPM and normal pressure.
   The wire # 229501 is tightened by turning the rigging screw at the hydraulic cylinder.

2. The hydraulic system has to be checked visually for leaks at the gasket, bleading valve, and connection during hydraulic pressure.

3. All movable parts must travel freely.
   Metal guide an movable plastic guide block are applied with teflon spray # 407716 in order to ensure low friction.

4. When resetting the tip, check that the trailing edges of the tip align with the trailing edges of the blade, as soon as the pivoting movement stops. Check this alignment at app. 20 mm. gap between the tip and the blade.
   If the trailing edges do not align when the turning movement stops, the stopcollar (126401) has to be adjusted.

5. Check the fixing of the blade tips to the blade by means of the 2 conical nylon guides # 064801.

6. Overspeed: Check that the release of the tip spoiler takes place within the fixed interval.

Annual service inspection:

Same as at the 3½ months' inspection, also inspect the following:

1. Check on corrosion on all metallized parts (only at the rootend of the blade) and repair.

2. Check that the sealing between bladeflange (#114201) and GRP-blade is intact.

3. Demount inspection cover (079801) and lid (126901).

4. Check eye screw (126601) for proper fit into the shaft (008705). Locking nut must be present and tightened.

5. Check the wire (229501) connection to the eye screw (126601). A split must be present.

6. Check Circlip ring (128901) for damage and proper mounting.

7. Check guideblock house visually for dirt.

8. Check guideblock for excessive clearance. While deployed, force the tip up and down. Under this manoevre the trailing moves beyond a +/- 15 mm limit.

22.04.99/TM

SERVICING OF THE HYDRAULIC TIPSPOILER OF THE LM 19.1 BLADE.

Annual service inspection:

Same as at the 3½ months inspection, also inspect the following:

9. Inspect nylon cones (064801) for screw wear.

10. Reinstall all the covers. Fill up the 4 bolt holes with Sikaflex and smoothe out the surface.

26.04.95
TM

SERVICING OF STANDARD LM LIGHTNING CONDUCTING SYSTEM.

Replacement of lightning receptor.

When lightning receptors are struck by lightning, they are exposed to very high temperatures which are capable of evaporating some of the material from the lightning receptor.
Lightning receptors are therefore shaped and mounted in such a way that replacement is possible. Replacement of lightning receptors is performed as follows:

a. Remove the old receptor from the tip by means of a special tool. Use the two small holes in the surface of the receptor, if they are intact. Alternatively the old receptor must be removed by drilling.

b. Remove the old sealer from the hole for the receptor and degrease thoroughly.

c. Grind the new receptor to a matt finish on the sides and degrease thoroughly.

d. Apply two droplets of adhesive to receptor thread (Loctite 243). Install the receptor in the thread and tighten it by means of a special tool. Use the two small holes in the surface of the receptor.

e. Fill the groove between the receptor and the blade as well as the two small holes in the surface with a sealer. Groove and holes are filled from bottom to top to avoid air holes under the surface. Remove excess sealer, if any.

Replacement of frame connection.

To protect the hydraulic cylinder against lightning current, a frame connection is mounted from the rigging screw to the root flange. The frame connection is mounted directly from the rigging screw to the flange, or by means of fittings and strips. If the frame connection is subject to replacement due to wear etc., a similar frame connection should be used, i.e. the sectional area, length and the mounting have to be the same. Deviation in sectional area, length and mounting could cause damage to the hydraulic cylinder and the frame connection.

04.06.97
FML

ERROR LOCATION

1.If one or both of the bladetips are moving sluggish, this may be caused by the following:

a. The bleeding filter # 065901 is blocked and has to be replaced.

b. Blocked nozzle # 203001, caused by dirt in the hydraulic fluid. All fluid of the whole hydraulic system has to be washed out 25 times and filtered to 10μ.

c. Dirt or wear and tear in the mechanical parts. Inspect all movable parts. Clean and grease.

2. If one or more of the bladetips are moving fast with high sound:

a. Nozzle # 203001 is missing.

b. Air in the hydraulic system. Airing through test nipple # 056011 until you are sure that there is no more air in the system.

Repeated bladetip activations with the two abovementioned errors will damage the blade badly, why it is of great importance to inspect before starting the rotor in connection with servicing.

24.11.93
KB/SM

REPAIR INSTRUCTIONS - FIBRE GLASS REINFORCED POLYESTER.

1. SANDING OF DAMAGED AREA.

   The damaged area is sanded (sandpaper with grain size 80-120) until the surface is completely clean. The area is then washed with acetone in order to remove the slip and to ensure complete dryness.

2. BUILDING-UP OF DAMAGED AREA

   If the damaged area has a depth exceeding approx. 1 mm, it is necessary to build up the area with fibre glass reinforced polyester until the built-up area is approx. 0.5 - 0.8 mm lower than the surrounding surface. If a fibre glass mat with a weight of 450 g/m² is used, each fibreglass laminate will have a thickness of approx. 1 mm. When the fibre glass laminate has hardened, gelcoat is used to complete the building-up process.

The actual process is as follows:

A. Always make sure that the polyester has been accelerated (cobalt naphtanate added). This is done by mixing 1-2 cm^3 with approx. 5 drops of catalyst (hardener). If the consistency of the mixture remains constant after 20-30 minutes at 18-20° C, the polyester cannot be used until accelerator (cobalt naphtanate) has been added. Contact your polyester supplier.

B. Never mix more than can be used within 15 minutes.

   Use 15 - 20 ml hardener (1.5 - 2,0%) for each kg polyester. After thorough mixing, the mixture is applied with a brush to the sanded area. The fibreglass mat is then placed on top and worked-up with a metal roller until the fibreglass is saturated. This procedure is repeated until the sanded area is almost level with the surrounding area (see point 2).

   When the fibreglass laminate has hardened, gelcoat is applied (layer thickness 0.5 - 1.0 mm, hardener 2.0 - 2.5%), until the entire repaired area is higher than the surrounding area.

   The repaired area is then wet-sanded (sandpaper grain size 300) until the repaired area is almost flush with the surrounding area.
   Sanding is then completed with wet sandpaper, grain size 600.

NB:Always remember to use abundant water when wet-sanding. After the last sanding, the repaired area should be polished 2-3 times with wax, giving the surface a smooth and glossy finish.

Installation

Installation in enclosure (box, cubicle) or locked, dry and clean room. Auxiliary contact terminals are finger proof (degree of protection IP 20). Main terminals are not protected. Except for the terminals, no live parts are accessible.
The contactor can be mounted on a vertical or sloping wall which has a horizontal or vertical circuit, on a desk or suspended from the roof.

EH 80...145 are installed with two diagonally placed M5 screws,
EH 150...800, EK 100...EK 550 with four M6 screws. Mounting hardware kit with damping devices comes with the contactor sizes EH 250...EH 800 and EK 160...550.

The minimum distance between arc-chute and unisolated wall has to be:

For	Min.
EH 80...90	30 mm
EK 100...145, EK 100	40 mm
EH 150...160, EK 160	15 mm
EH 250	30 mm
EH 370...800	40 mm
EK 370, EK 550	40 mm

The voltage of the contactor coil is stated next to the coil terminals (marked A1 and A2) and should correspond with the control voltage. The contactor will work within the voltage range 80 to 110 %.

Einbau

Einbau in Kapselungen (Kästen, Schränke) oder verschließbaren, trockenen und sauberen Raum.
Das Schütz hat berührungsgeschütze Hilfskontakt- und Spulenanschlüße (Finger- und Handrückensicher,
IP 20). Die Hauptanschlüße sind jedoch nicht berührungsgeschützt. Darüber hinaus hat das Schütze keine von außen erreichbare Spannungsführende Teile.
Die Schütze können an vertikale oder schräge Wand mit horizontalen oder vertikalen Strombanen, stehend oder "hängend" montiert werden.

EH 80...145 wird mit 2 diagonal versetzten M5 Schrauben angebaut.
EH 150...800, EK 100...EK 550 mit 4 St M6 Schrauben.
Einbausatz mit Dämpfelementen wird für Schützegrößen EH 250...EH 800 und EK 160...550 mitgeliefert.

Mindesabstand zwischen Lichtbogenkammer und unisolierter Wand:

Für	Min.
EH 80...90	30 mm
EH 100...145, EK 100	40 mm
EH 150...160, EK 160	15 mm
EH 250	30 mm
EH 370...800	40 mm
EK 370, EK 55	40 mm

Die Nennspannung der Schützspule ist an den Spulenanschlüßen angegeben (mit A1 und A2 vermerkt) und soll mit der Betätigungsspannung übereinstimmen. Das Schütz funktioniert auch wenn Spannungsvariationen von 80 - 110 % vorkommen.

Installation

Installation sous enveloppe (coffret ou armoire) ou dans un local sec et propre, fermé. Les bornes des circuits auxiliaires sont protégées contre le toucher (protection IP 20). Les bornes de puissance ne sont pas protégées. Hormis les bornes de puissance, la protection contre le toucher de toute pièce sous tension est assurée.

Fixation des contacteurs:
Les contacteurs peuvent-être montés horizontaux , verticaux ou suspendus.
EH 80...145 se fixent par deux vis M5 en diagonale,
EH 150...800, EK 100...EK 550 se fixent par quatre vis M6. Les contacteurs EH 250...EH 800 et EK 160...550 sont livrès avec un kit de fixation et avec silent block

La distance à la masse de la chambre de coupure (face avant) doit être au minimum de:

Pour	
EH 80...90	30 mm
EH 100...145, EK 100	40 mm
EH 150...160, EK 160	15 mm
EH 250	30 mm
EH 370...800	40 mm
EK 370, EK 550	40 mm

La tension et la fréquence de chaque bobine sont marquées à coté des bornes bobine (repérées A1, A2) et doivent correspondre à celles des circuits de contrôle. Le contacteur peut fonctionner dans une plage de tension comprise entre 80 % et 110 % de la tension nominale.

Installation

Installation i kapsling (låda, skåp) eller låst, torrt och rent rum. Kontaktorn har beröringsskyddade hjälpkontakt- och spoluttag (fingersäkra, IP 20 men huvuduttagen är inte beröringsskyddade. Kontaktorn har för övrigt inga utifrån åtkomliga spänningsförande delar. Kontaktorn kan monteras på vertikal eller lutande vägg med horisontal eller vertikal strömbana, på bord eller i tak.

EH 80...145 monteras med 2 diagonalt placerade M5-skruvar,
EH 150...800, EK 100...EK 550 med 4 st M6 skruvar. Monteringssats med dämpdon medföljer kontaktorstorlekarna EH 250...EH 800 och EK 160...550.

Vid montering ska avståndet mellan ljusbågsskärm och oisolerad vägg vara:

För	Min. mått
EH 80...90	30 mm
EH 100...145, EK 100	40 mm
EH 150...160, EK 160	15 mm
EH 250	30 mm
EH 370...800	40 mm
EK 370, EK 550	40 mm

Kontaktorspolens märkspänning står angiven vid spoluttagen (märkta A1 och A2) och ska överensstämma med manöverspänningen. Kontaktorn fungerar även om spänningsvariationer på 80–110 % förekommer.

Installazione

Installazione in custodia (cassetta, armadio) o locale asciutto, pulito e lucchettato. I morsetti dei contatti ausiliari e le parti attive, ad eccezione dei morsetti principali, sono protetti contro il contatto accidentale, (grado di protezione IP 20). E' possibilie montare il contattore in verticale, in orizzontale o sospeso.

I contattori da **EH 80 a 145** vengono installati mediante 2 viti M5 collocate agli estremi diagonali.
I contattori da EH 150 a 800, EK 100 a EK 550 con 4 viti M6. I contattori da EH 250 a EH 800, EK 160 a 550 vengono forniti muniti di viti e ammortizzatori di gomma.

La distanza minima tra la caduta dell'arco e la parete non isolata deve essere:

Per	
EH 80...90	30 mm
EH 100...145, EK 100	40 mm
EH 150...160, EK 160	15 mm
EH 250	30 mm
EH 370...800	40 mm
EK 370, EK 550	40 mm

La tensione della bobina del contattore è indicata vicino ai morsetti della bobina (indicati con A1 e A2) e deve corrispondere alla tensione di comando. Il contattore lavora con un campo da 80 a 110 % della tensione.

Instalación

Instalación en una envolvente (caja, cubículo) o en una sala cerrada, seca y limpia. Los bornes de los contactos auxiliares están protegidos contra contactos fortuitos con los dedos (grado de protección IP 20). Los bornes principales no están protegidos. A excepción de los bornes, no puede accederse a ninguna pieza conductora de la electricidad. Es posible instalar el contactor sobre un plano vertical, horizontal o suspendido.

Los **EH 80...145** se instalan con dos tornillos M5 en diagonal, los **EH 150...800, EK 100...EK 550** se instalan con 4 tornillos M6. El kit de componentes de fijación con amortiguadores se incluye en el suministro de los contactores de tamaños EH 250...EH 800 y EK 160...550.

La distancia mínima entre la cámara de soplado del arco y la pared no aislada debe ser de:

Para	Mínimo
EH 80...90	30 mm
EH 100...145, EK 100	40 mm
EH 150...160, EK 160	15 mm
EH 250	30 mm
EH 370...800	40 mm
EK 370, EK 550	40 mm

La tensión de la bobina del contactor se indica juntoi a los bornes de la bobina (marcados como A1 y A2) y debería coincidir con la tensión de mando. El contactor funcionará correctamente con unas tensiones comprendidas entre el 60 y el 110 %.

Short-circuit protection

The contactor should be short-circuit protected by series connected fuses in the main circuit. Maximum permitted blade fuses (time/current zone gI, gL or gG) as following:

Contactor size	Max. fuse (without relay) Type 2 acc. to IEC 947-4-1
EH 80	125 A
EH 90	160 A
EH 100, EK 100	200 A
EH 145	250 A
EH 150, 160	355 A
EK 160	355 A
EH 250	500 A
EH 370, EK 370	630 A
EH 550, EK 550	630 A
EH 700, 800	800 A

Schutz gegen Kurzschluß

Das Schütz soll gegen Kurzschluß in der Hauptstrombahn geschützt werden. Werden gewöhnliche NH-Sicherungseinsätze verwendet (Auslösekennwerte gI, gL oder gG) sind folgende max Sicherungen zulässig.

Schütz Grösse	Max. Sicherung (ohne Relais) Typ 2 laut IEC 947-4-1
EH 80	125 A
EH 90	160 A
EH 100, EK 100	200 A
EH 145	250 A
EH 150, 160	355 A
EK 160	355 A
EH 250	500 A
EH 370, EK 370	630 A
EH 550, EK 550	630 A
EH 700, 800	800 A

Protection contre les courts-circuits

Cette protection peut être assurée soit:

- par disjoncteur (demander tableaux de coordination).
- par fusibles gI, gL ou gG, en série avec circuit de puissance

Contacteur type	Fusible maxi (sans relais thermique) Type 2 selon IEC 947-4-1
EH 80	125 A
EH 90	160 A
EH 100, EK 100	200 A
EH 145	250 A
EH 150, 160	355 A
EK 160	355 A
EH 250	500 A
EH 370, EK 370	630 A
EH 550, EK 550	630 A
EH 700, 800	800 A

Kortslutningsskydd

Kontaktorn ska skyddas mot kortslutning i huvudströmbanan. Används vanliga knivsäkringar (utlösningskarakteristik gI, gL eller gG) tillåts max säkring enligt följande

Kontaktor-storlek	Max säkring (utan relä) Typ 2 enligt IEC 947-4-1
EH 80	125 A
EH 90	160 A
EH 100, EK 100	200 A
EH 145	250 A
EH 150, 160	355 A
EK 160	355 A
EH 250	500 A
EH 370, EK 370	630 A
EH 550, EK 550	630 A
EH 700, 800	800 A

Protezione contro il corto circuito

Il contattore può essere protetto contro il corto circuito collegando dei fusibili in serie al circuito principale. La massima portata dei fusibili (tempo/corrente per tipi gI, gL o gG) à la seguente:

Taglia del contattore	Fusibile max. (senza relé) Tipo 2 Secondo IEC 947-4-1
EH 80	125 A
EH 90	160 A
EH 100, EK 100	200 A
EH 145	250 A
EH 150, 160	355 A
EK 160	355 A
EH 250	500 A
EH 370, EK 370	630 A
EH 550, EK 550	630 A
EH 700, 800	800 A

Protección contra cortocircuitos

El contactor deberá protegerse contra cortocircuitos mediante fusibles conectados en serie en el circuito principal. Los fusibles máximos permitidos (zona tiempo/corriente, gI, gL o gG) deben ser los siguientes:

Tamaño contactor	Fusible máximo (sin relé) Tipo 2 según IEC 947-4-1
EH 80	125 A
EH 90	160 A
EH 100, EK 100	200 A
EH 145	250 A
EH 150, 160	355 A
EK 160	355 A
EH 250	500 A
EH 370, EK 370	630 A
EH 550, EK 550	630 A
EH 700, 800	800 A

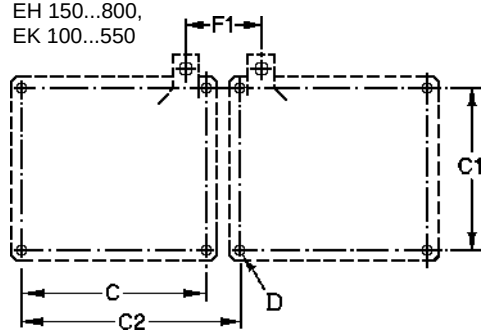
EH 150...800,
EK 100...550



1) Smallest distance.
2) Gives min. distance F1 = distance between the poles, on one contactor.
3) Allows space for three auxiliary contact blocks between the contactors.
4) Allows space for four auxiliary contact blocks between the contactors.
5) Screws and damping elements are included.

1) Mindestabstand.
2) Ergibt Maß F1 ≈ Maß zwischen den Phasen bei einem Schütz.
3) 3 Blöcke zwischen den Schützen.
4) 4 Blöcke zwischen den Schützen.
5) Schrauben und Dämpfelement einbegriffen.

1) Distance minimum possible.
2) Entraine F1 = entr'axe entre pôles principaux sur un contacteur
3) Avec 3 blocs de contacts auxiliaires montés entre les 2 contacteurs.
4) Avec 4 blocs de contacts auxiliaires montés entre les 2 contacteurs.
5) Visserie et silent bloc inclus

1) Minsta möjliga mått
2) Ger min. mått F1 = kontaktorns fas- avstånd
3) Ger plats för tre hjälpkontaktblock mellan kontaktorerna.
4) Ger plats för fyra hjälpkontaktblock mellan kontaktorerna.
5) Skruv och dämpdon ingår.

1) Distanza minima.
2) Indica la distanza F1, cioè la distanza fra le fasi di un contattore.
3) Con 3 blocchi di contatti montati fra i contattori .
4) Con 4 blocchi di contatti montati fra i contattori .
5) Viti e ammortizzatori sono compresi.

1) Mínima distancia permitida.
2) Indica la distancia F1 = distancia entre los polos de un contactor.
3) Caben 3 bloques de contacto entre los contactores.
4) 4 bloques de contacto entre los contactores.
5) Se incluyen tornillos y gomas amortiguadoras para la instalación.

Before any dismantling of the contactor

Make dead by,
- turning off the contactor.
- opening the main circuit by turning off the main switch, if any, or by removing the main fuses in all three phases.
- To protect against making attempt, open also the control circuit.

Maßnahmen vor dem Zerlegen des Schützes

- Schütz ausschalten.
- Hauptstrom über Trennschalter oder Leistungsschalter ausschalten oder die Hauptsicherungen in allen drei Phasen herausnehmen.
- Um Einschaltversuche zu verhindern auch die Betätigungsstrombahnen öffnen.

Avant tout démontage du contacteur

- Mettre hors tension le contacteur.
- Ouvrir le circuit de puissance en cadenassant en position ouverte le dispositif de sectionnement en amont du contacteur ou à défaut en enlevant les fusibles de puissance sur toutes les phases.
- Mettre hors tension le circuit de contrôle pour protéger contre toute fermeture intempestive.

Före ingrepp i kontaktorn

- Gör spänningslöst genom att slå ifrån kontaktorn.
- Bryt huvudströmmen genom att slå ifrån frånskiljare eller effektbrytare eller genom att ta ur huvudsäkringen i alla tre faserna.
- För att förhindra tillslagsförsök, bryt även manöverströmbanan.

Prima di amontare il contattore

Disattivarlo mediante
- disalimentazione del contattore
- apertura del circuito principale spegnendo l'interruttore principale, se esiste o rimuovendo i fusibili dalle 3 fasi.
- Per una protezione più completa aprire anche il circuito di comando.

Antes de desmontar el contactor

Desactívelo:
- desconectando el contactor.
- abriendo el circuito principal desconectando para ello el interruptor principal, si existe, o desmontando los fusibles principales de las tres fases.
- para proteger contra cualquier intento de conexión, abra también el circuito de mando.

Change of contacts

The change can be done on an installed contactor. Replace all of the main contacts at the same time.

EH 80 and 90

- Remove the arc-chute.
- Remove the moving contacts. By lifting and pushing them forward, they will go free from the clamp which holds them in position. See the figure.
- Exchange the fixed contacts.
- Put in the new moving contacts.

EH 100 and 145

- Remove the arc-chute.
- Press out the moving contacts. Lift the contact somewhat to let the contact easier slide out.
- Exchange the fixed contacts.
- Put in the new moving contacts.

Kontaktwechsel

Der Austausch kann auf montiertes Schütz erfolgen. Sollte ein Hauptkontaktstück ausgetauscht werden, tausche alle.

EH 80 und 90

- Entferne Lichtbogenkammer.
- Entferne die beweglichen Kontaktstücke. Hebe und schiebe gleichzeitig das Kontaktstück vorwärts so daß es aus der Bügelhalterung herauskomt. Siehe Fig. unten.
- Tausche danach die festen Kontaktstücke.
- Nehme bewegliche Kontaktstücke einsetzen.

EH 100, 145 und EK 100

- Entferne Lichtbogenkammer.
- Entferne die beweglichen Kon taktstücke. Die Kontaktstücke gleich zeitig etwas aufwärts he ben so daß dieselben leichter herausgeschoben werden können.
- Tausche danach die festen Kontaktstücke.
- Neue bewegliche Kontaktstücke einsetzen.

Remplacement des contacts

Peut se faire sur un contacteur installé. Remplacer tous les contacts principaux en même temps.

EH 80 et 90

- Enlever la cage de soufflage.
- Démontage des contacts mobiles: soulever le contact d'un seul coté en poussant vers l'avant pour qu'il échappe à son verrouillage (voir dessin).
- Changer les contacts fixes.
- Mettre les nouveaux contacts mobiles.

EH 100, 145 et EK 100

- Enlever la cage de soufflage.
- Pousser les contacts mobiles: Soulever légérement le contact pour qu'il glisse plus facilement.
- Changer les contacts fixes.
- Mettre les nouveaux contacts mobiles.

Byte av kontakter

Byte kan göras med kontaktorn installerad. Om någon huvudkontakt behöver bytas, byt alla.

EH 80 och 90

- Tag bort ljusbågsskärmen.
- Tag bort de rörliga kontakterna. Genom att lyfta och samtidigt skjuta kontakten framåt går den fri från bygeln som håller den på plats. Se nedanstående figur.
- Byt därefter de fasta kontakterna.
- Sätt i de nya rörliga kontakterna.

EH 100, 145 och EK 100

- Tag bort ljusbågsskärmen
- Tag bort de rörliga kontakterna. Lyft samtidigt kontakten något uppåt så att kontaktbelägget går fritt. Se nedanstående figur.
- Byt därefter de fasta kontakterna.
- Sätt i de nya rörliga kontakterna.

Sostituzione dei contatti

La sostituzione può essere effettuata su un contattore installato. Sostituire i contatti principali tutti insieme.

EH 80 e 90

- Togliere la camera spegniarco.
- Rimuovere i contatti mobili sollevandoli e spingendoli in avanti; si sganceranno cosí dal morsetto che li tiene agganciati in posizione. Vedere figura.
- Sostituire i contatti fissi.
- Inserire i nuovi contatti mobili.

EH 100, 145 e EK 100

- Togliere la camera spegniarco.
- Spingere fuori i contatti mobili facendo pressione su un lato. Vedere figura.
- Sostituire i contatti fissi.
- Inserire i nuovi contatti mobili.

Cambio de contactos

La sustitución puede realizarse en un contactor instalado. Cambie todos los contactos principales al mismo tiempo.

EH 80 y 90

- Desmonte la cámara de soplado del arco.
- Desmonte los contactos móviles. Elevándolos y empujándolos hacia adelante, se liberarán de la abrazadera que los sujeta en su posición. Véase la figura.
- Cambie los contactos fijos.
- Introduzca los nuevos contactos móviles.

EH 100, 145 y EK 100

- Desmonte la cámara de soplado del arco.
- Extraiga los contactos móviles. Levante ligeramente el contacto para permitir que éste salga más fácilmente deslizándose.
- Cambie los contactos fijos.
- Introduzca los nuevos contactos móviles.

Change of contacts EH 150...800, EK 160...550

- Remove the arc-chute, see page 7.
- **EH 150...800, EK 160...550** Press out the moving contacts, see Fig. 1.
- **EH 370...800, EK 370...550** Moving main contacts: Lift the respective clamp and press the contact into neutral position. See Fig. 2. Remove the contacts.
- Exchange the fixed contacts. See Fig. 3.
- Put in the new movable contacts.

Kontaktwechsel EH 150...800, EK 160...550

- Entferne Lichtbogenkammer, siehe Seite 7.
- **EH 150...800, EK 160...550** Die beweglichen Schaltstücke herausschieben. Siehe Fig. 1.
- **EH 370...800, EK 370...550** Bewegliche Hauptschaltstücke: Hebe den jeweiligen Haltebügel und schiebe das Kontaktstück heraus so daß es entfernt werden kann. Siehe Fig. 2.
- Feste Kontaktstücke austauschen. Siehe Fig. 3.
- Neue bewegliche Kontaktstücke einsetzen.

Remplacement des contacts EH 150...800, EK 160...550

- Enlever la gace de soufflage (voir page 7)
- **EH 150...800, EK 160...550:** Pousser les contacts mobiles : (voir figure 1)
- **EH 370...800, EK 370...550:** L'opération précédente permet d'ôter les contacts d'arc. Pour enlever les contacts principaux: Soulever le portecontacts avec un tournevis en utilisant un contact d'arc comme cale puis pousser le contact principal en position déverrouillée (voir figure 2), et le sortir.
- Changer les contacts fixes (voir figure 3).
- Monter les nouveaux contacts mobiles.

Byte av kontakter EH 150...800, EK 160...550

- Tag bort ljusbågsskärmen, se sida 7.
- **EH 150...800, EK 160...550** Tryck ut de rörliga kontakterna, se Fig. 1.
- **EH 370...800, EK 370...550** Rörliga huvudkontakter: Lyft upp respektive bygel och skjut kontakten i friläge. Se Fig. 2. Tag därefter bort kontakterna.
- Byt ut de fasta kontakterna. Se Fig. 3.
- Montera därefter de nya rörliga kontakterna.

Sostituzione dei contatti per EH 150...800, EK 160...550

- Rimovere la camera spegniarco, vedere pag. 7.
- **EH 150...800, EK 160...550** sollevare tirando i contatti mobili, vedere Fig. 1.
- **EH 370...800, EK 370...550** Contatti mobili principali: sollevare i rispettivi morsetti e spingere il contatto nella posizione neutra, vedere Fig. 2. Rimuovere i contatti.
- Sostituire i contatti fissi, vedere Fig. 3.
- Sostituire i nuovi contatti principali mobili.

Cambio de contactos EH 150...800, EK 160...550

- Desmonte la cámara de soplado del arco, véase página 7.
- **EH 150...800, EK 160...550** Extraiga los contactos móviles, véase Figura 1.
- **EH 370...800 , EK 370...550** Extrayendo los contactos principales: extraiga la abrazadera respectiva y desplace el contacto a la posición de punto muerto.Véase Fig. 2. Desmonte los contactos.
- Cambie los contactos fijos. Véase Fig. 3.
- Introduzca los nuevos contactos móviles.

Fig. 1
EH 150 ...800, EK 160...550

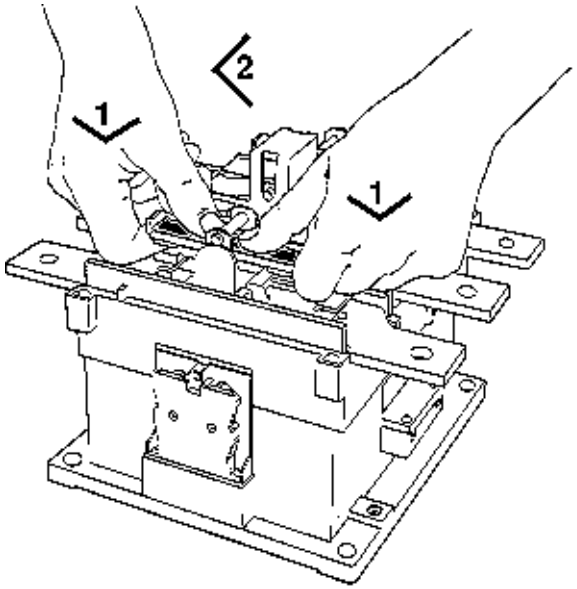

Fig. 2
EH 370 ...800, EK 370...550

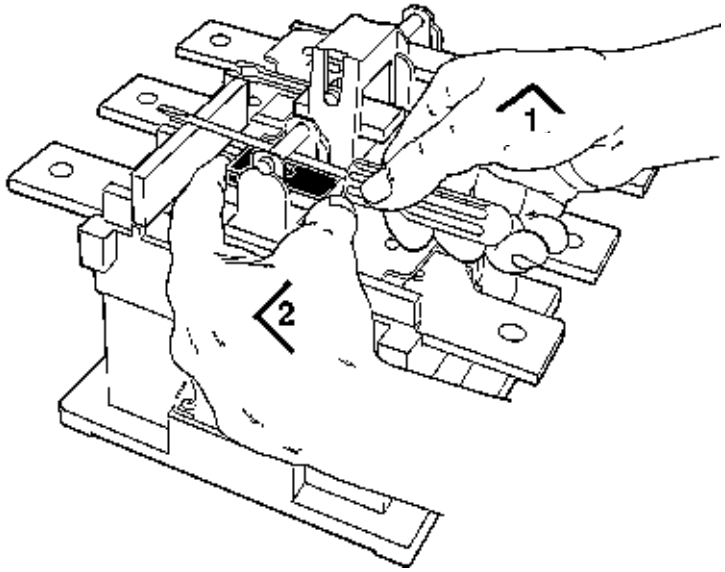

Fig. 3
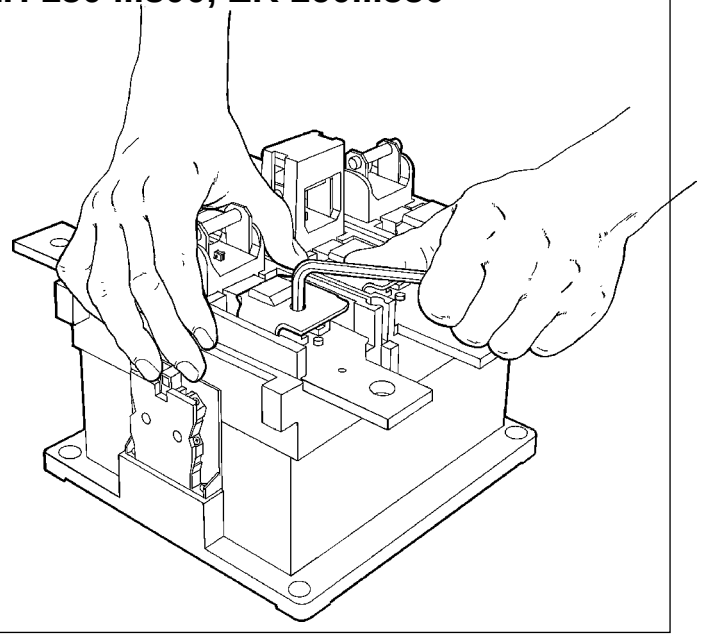
EH 150 ...800, EK 160...550



Change coil on EH 80...145

To be done on work bench (installed contactor must be removed).

- Change coil according to Fig. 1. Make sure that the return springs will fit into the guide ho les in the coil when the contac tor is replaced on the plate.

EH 150...800, EK 100...550

On installed contactor, main cables and coil cables must be loosened.

- Change coil according to Fig. 2. Make sure that the return springs will fit into the guide holes in the coil when the contactor is replaced on the plate.

Coils see page 10.

Spulenwechsel EH 80...145

Wird auf einer Arbeitsbank vorgenommen (Schütz muß vom Aufstellungsplatz abmontiert werden)

- Spulentausch laut Fig. 1. Kontrolliere daß die Führungs vertiefungen in der Spule hinein kommen wenn das Schütz wie der auf die Grundplatte montiert wird.

EH 150...800, EK 100...550

Schütz braucht nicht abmontiert werden aber die Hauptstrom- und Spulenkabeln müßen gelöst werden.

- Spulentausch laut Fig. 2. Kontrolliere daß die Führungs- vertiefungen in der Spule hineinkommen wenn das Schütz wieder auf die Grundplatte moniert wird.

Spulen siehe Seite 10

Changement de bobine EH 80...145

Doit se faire sur une table (un contacteur installé doit être démonté).

- Changer la bobine (voir figure 1). Bien s'assurer que les ressorts de rappel sont bien engagés dans les logements de la bobine quand on refixe le contacteur sur sa plaque.

EH 150...800, EK 100...550

Sur un contacteur installé, les cables de puissance et ceux de la bobine doivent être déconnectés.

- Changer la bobine (voir figure 2). Bien s'assurer que les ressorts de rappel sont bien engagés dans les logements de la bobine quand le contacteur est refixé sur sa base.

Bobines voir page 10.

Byte av spole EH 80...145

Utförs på arbetsbänk (installerad kontaktor måste tas loss)

- Byt spole enligt Fig. 1. Se till att frånslagningsfjädrarna kommer rätt i styrhålen i spolen när kontaktorn ställs tillbaka på plåten.

EH 150...800, EK 100...550

På installerad kontaktor måste huvud- och spolkablar lossas.

- Byt spole enligt Fig. 2. Se till att frånslagningsfjädrarna kommer rätt i styrhålen i spolen när kontaktorn ställs tillbaka på plåten.

Spolar se sidan10.

Sostituzione della bobina su EH 80...145

Da effetturare su un piano di lavoro (rimuovere il contattore se installato).

- Sostituire la bobina come da Fig. 1. Accertarsi che la molla di ritorno si adatti ai fori guida della bobina quando il contattore viene rimesso sulla piastra.

EH 150...800, EK 100...550

Sui contattori installati è necessario allentare i cavi principali e quelli della bobina.

- Sostituire la bobina come da Fig. 2. Accertarsi che la molla di ritorno si adatti ai fori guida della bobina quando il contattore viene rimesso sulla piastra.

Bobine vedere pag.10.

Cambio de las bobinas EH 80...145

Debe realizarse en un banco de taller (debe desmontarse el contactor instalado)

- Cambie la bobina según la Fig. 1. Asegúrese de que los muelles de recuperación entran en los agujeros guía de la bobina cuando se coloca de nuevo el contactor sobre la placa.

EH 150...800, EK 100...550

Con el contactor instalado, debe aflojar los cables principales y los cables de la bobina.

- Cambie la bobina según la Fig. 2. Asegúrese de que los muelles de recuperación entran en los agujeros guía de la bobina cuando se coloca de nuevo el contactor sobre la placa.

Bobinas véase página 10.

EH 80...145

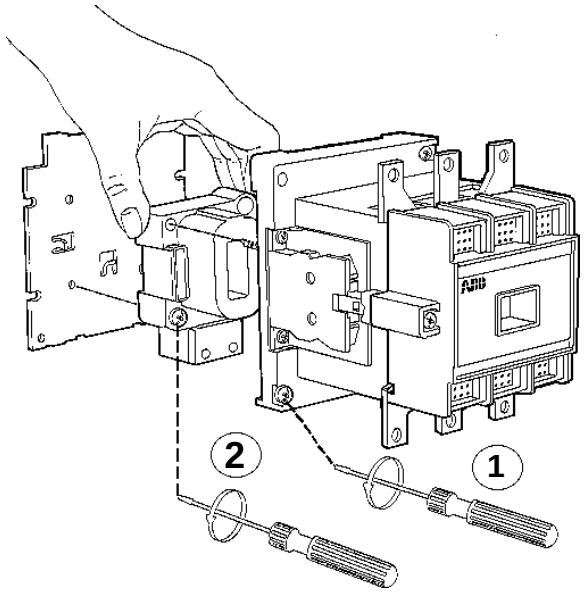

Fig. 2
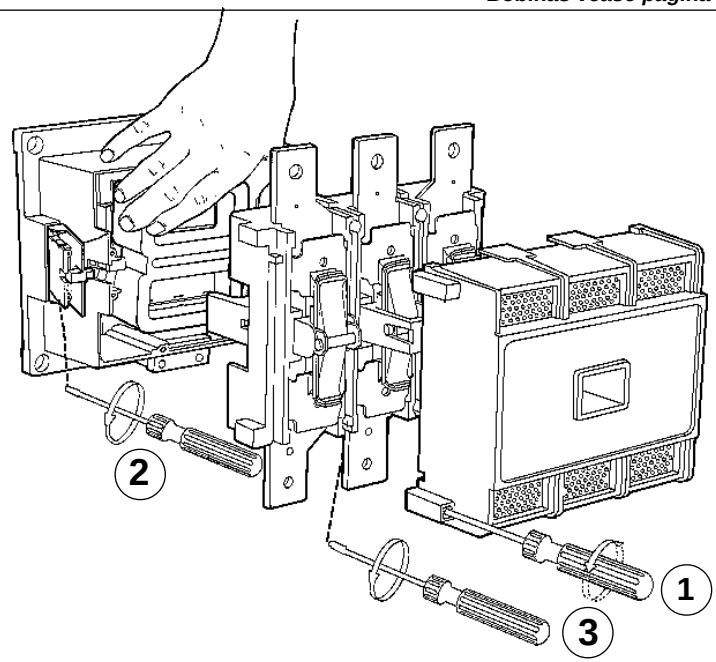
EH 150...800, EK 100...550



ACCESSORIES

Additional auxiliary contact blocks

AC-version
A maximum of 3 blocks can be mounted on the contactor beyond the one mounted as standard. Technically, all blocks are identical, which means that the same block can be used in all three positions. If the demand for correct position marking has to be met, order block B, C etc. mounted as shown in the figure 1.

DC-version
A maximum of 1 contact block can be mounted on the contactor's left side. The right side is blocked by the operating unit for DC.

1) **SK 829 002-E** is a special auxiliary contact block with overlapping. Can be mounted on the contactor's right side only . No other block can be mounted outside (figure 2). Contact 35–36 has late opening. 47–48 has late closing.

2) **Block A,** spare for the contactor's auxiliary contact block.

ZUBEHÖR

Zusätzliche Hilfsschalterblöcke

Drehstromausführung
Höchstens 3 Kontaktblöcke außer dem in der Lieferung bereits erhaltenen Kontaktblock, können am Schütz montiert werden. Technisch sind die Blöcke gleichwertig, der gleiche Block kann also auf allen drei Plätzen angewendet werden. Falls jedoch verschiedene Anschlußbezeichnungen gefordert werden, bestellt man Block B, C und D die gemäß Fig. 1 angebracht werden.

Gleichstromausführung
Höchstenst 1 Kontaktblock kann auf der linken Seite des Schützes angebracht werden. Die rechte Seite ist vom Sparwiederstand besetzt.

1) **SK 829 002-E** ist ein spezieller Hilfskontaktblock mit Überlappung. Kann nur auf der rechten Seite des Schützes angebracht werden. Kein weiterer zusätzlicher Block kann montiert werden. Die Kontakte 35–36 haben Öffnungsverzug, und 47–48 haben Schließverzug

2) **Block A** ist Ersatz für den befindlichen Block.

ACCESSOIRES

Contacts auxiliaires supplémentaires

Pour contacteurs avec circuit de commande en courant alternatif – AC
3 blocs de contacts auxiliaires supplémentaires peuvent être montés sur l'appareil standard livré avec le bloc A monté. Les blocs sont montables indifféremment dans les 3 positions, cependant si on veut conserver un repérage correct, il faut respecter l'ordre de montage indiqué B–C...(Fig. 1).

Pour contacteurs avec circuit de commande en courant continu– DC
Un seul bloc de contacts auxiliaires peut être ajouté à gauche du contacteur. Le côté droit est occupé par le "bloc: résistance d'economie et contact d'insertion".

1) **SK 829 002-E** est un bloc de contacts auxiliaires spécial à re couvrement. Il doit être monté à droite du contacteur et ne permet pas de rajouter un bloc de contacts auxiliaires supplémentaire (Fig. 2). Le contact 35–36 est à ouverture retardée. Le contact 47–48 est à fermeture avancèe.

2) **SK 829 002- A** est livré monté sur le contacteur standard et peut être commandé en rechange.

TILLBEHÖR

Extra hjälpkontakt-block

Växelströmsutförande
Högst 3 kontaktblock kan monteras på kontaktorn, utöver det som finns där vid leveransen. Tekniskt är blocken likadana, så samma block kan användas på alla tre platserna. Men om krav på skilda uttagsbeteckningar finns beställs block B, C och D som placeras enligt figur 1.

Likströmsutförande
Högst 1 kontaktblock kan monteras på kontaktorns vänstra sida. Höger sida är blockerad av manöverenheten för likström.

1) **SK 829 002-E** är ett speciellt hjälpkontaktblock med överlappning. Kan endast placeras på kontaktorns högra sida. Inget ytterligare block kan monteras utanpå. Kontakt 35–36 har sen brytning och 47–48 har sen slutning.

2) **Block A** är ersättning för befintligt block.

ACCESSORI

Blocchetti aggiuntivi di contatti ausiliari

Versione in c.a.
Possono essere montati fino *a un massimo di 3 blocchetti* di contatti oltre a quello già montato di fabbrica. Tecnicamente tutti i blocchetti sono identici, il che significa che lo stesso blocchetto può essere montato in tutte e 3 le posizioni. Se viene richiesta la corretta numerazione del morsetti, è necessario ordinare il blocchetto B, C ecc. e montarlo come indicato nella figura 1.

Versione in c.c.
Può essere montato *un solo blocchetto* di contatti ausiliari sul lato sinistro del contattore. Il lato destro è occupato dalla resistenza in c.c.

1) **SK 829 002-E** è un blocchetto speciale di contatti ausiliari a doppia punta. Può essere montato solo sul lato destro del contattore e non è possibile aggiungere altri contatti su quel lato. (Figura 2). Il contatto 35–36 è ritardato all'apertura, il 47–48 è ritardato in chiusura.

2) **Blocchetto A,** ricambio del blocchetto di contatti ausiliari montato di serie sul contattore.

ACCESORIOS

Bloques adicionales de contactos auxiliares

Versión c.a.
Puede instalarse *un máximo de 3 bloques* en el contactor, aparte del ya instalado de forma estandár. Técnicamente, todos los bloques son idénticos, lo que supone que puede emplearse el mismo bloque en las tres posiciones. Si debe cumplirse la exigencia de una identificación correcta de las numera, solicite los bloques B, C etc. instalados como se muestra en la Fig. 1.

Versión c.c.
Puede instalarse *un máximo de un bloque* de contactos en la parte izguierda del contactor. La parte derecha está bloqueada por la unidad de accionamiento para c.c.

1) **SK 829 002-E** es un bloque especial de contactos auxiliares con solapamiento. Puede instalarse sólo en la parte derecha del contactor. Ningún otro blo que puede instalarse fuera (Figura 2). Los contactos 35–36 tienen apertura retardada. Los 47–48 tienen cierre retardado.

2) **Bloque A,** recambio del bloque de contactos auxiliares del contactor.

NOTA: Si el contactor se monta junto con un relé térmico no necesita una protección especial sobre el lado del relé. Póngase en contacto con la Oficina de ventas más próxima.

Care

The contactors do not need any care except for an occasional check up of contact condition. The contact wear depends mainly on burning from the arc and will increase considerably when the contactor is used for inching or direct reversing (AC-4 operations; compare with the electrical endurance diagram in the catalogue). Contactors regularly used for AC-4 operations need more frequent inspections, but main contact exchange is not necessary until the contact tips are almost totally worn out.

Wartung

Die Schütze benötigen keine Wartung außer einer gelegentlichen Kontrolle, daß die Hauptkontakte nicht verschließen sind. Der Verschleiß beruht praktisch vollständig auf Abbrennung durch EIN- und AUS-schaltlichtbogen. Beachte, daß bei Betrieb, bei dem das Schütz oft den Startstrom ausschalten muß (Vorrücken, Direktumkehr), eine Inspektion öfter durchgeführt werden muß, vergleiche mit den Lebensdauerkennlinien im Katalog. Die Kontaktstücke brauchen jedoch nicht ausgewechselt zu werden, bevor die Schaltflächen fast ganz verschließen sind.

Entretien

Les contacteurs ne nècessitent aucun entretien, à l'exception de l'examen pèriodique de l'ètat des contacts. L'usure des contacts dépend surtout de l'érosion due à l'arc électrique et augmente considérablement quand le contacteur est utilisé en marche par à coups ou en inversion de sens de marche (catégorie d'emploi AC-4; voir courbes d'endurance électrique). Les contacteurs utilisés en catégorie AC-4 ont besoin d'examens périodiques, mais l'échange des contacts n'est pas nécessaire tant que leurs pastilles ne sont pas totalement usées.

Skötsel

Kontaktorerna behöver ingen skötsel annat än viss kontroll att inte huvudkontakterna är utslitna. Slitaget beror praktiskt taget helt på avbränning genom slut- och brytljusbågarna. Märk, att vid drift där kontaktorn ofta får bryta startströmmen (framryckning, direktreversering) ökar behovet av inspektion; jämför livslängdskurvorna i katalogen. Kontakterna behöver dock inte bytas förrän kontaktbeläggen är nästan helt utslitna.

Manutenzione

Il contattore non necessita alcuna manutenzione tranne nel caso di verifica delle condizioni dei contatti. L'usura dei contatti dipende principalmente dalle bruciature provocate dall'arco e aumenta notevolmente quando il contattore viene impiegato a scatti o per inversione (categoria d'impiego AC4; confrontare con diagramma di durata elettrica sul catalogo). I contattori utilizzatti in AC4 necessitano di controlli più frequenti, ma la sostituzione dei contatti non è necessaria se le estremità degli stessi non sono quasi totalmente consumate.

Cuidado

Los contactores no requieren ningún cuidado a exceptión de una comprobación ocasional del estado de los contactos. El estado de éstos depende fundamentalmente del quemado provocado por el arco y aumentará considerablemente cuando el contactor se emplee para avance paso a pso o para inversión directa (funcionamiento en la categoría de empleo AC-4; consulte la tabla de longevidad eléctrica del catálogo). Los contactos utilizados habitualmente para accionamientos de categoría AC-4 requiren una inspección más frecuente, pero el cambio de los contactos principales no es necesario hasta que las puntas de los contactos no están casi completamente desgastadas.

Mechanical wear	1
Maintenance of contacts	2
Interpreting levels of electrical contact wear	3
Changing contacts	5
Trouble shooting	8

Mechanical wear

The number of mechanical operations has a low impact on the life of the main contacts and their overall electrical life. However general information concerning mechanical wear could be of interest.

AC-Hum

Pollution of the magnet pole surfaces will create a slight hum coming from the contactor in the closed position.
When cleaning, use a soft and dry piece of cloth.
Hum can also occur if the pole surfaces are deformed.
A louder hum will occur if the shading coil is broken because the magnet will cause the contactor to chatter.
If so the contactor needs to be exchanged.

Another reason for AC-hum could be corrosion caused by environmental conditions that exceed the contactor specifications.

Contactors need to be protected from condensation in order to keep the pole surfaces of the magnet free from corrosion.
For more specific information regarding this please see the our technical catalogue, section: *Climatic withstand of devices.*

Contact bounce

The operational limit of the contactor is between 85 and 110% of the rated coil voltage.
A voltage variation of ± 5% will minimize the contact wear. The reason for this is that higher voltages will increase the speed of the electromagnet at closing. Lower voltages will decrease the speed at closing. Both these factors can lead to a higher level of contact bounce at closing. High voltage and the increased speed at closing also contribute to some increased sound level.

Maintenance of Contacts

A contact is not necessarily damaged or worn out, just because the surface is rough and discolored. The contacts in the figure below may look rather inferior but experience has shown that they are better than a new set of contacts.
This is because they are ”electrically seated” and make good contact over the entire surface.
Based on this it would be completely wrong to change a contact only by judging from the appearance of the surface.

Filing of contacts

Today, with highly developed contact materials and high performance contactors, filing, grinding, or other attempts to restore contacts or contact surfaces should be avoided.
Our experience shows that this increases the risk of causing other problems. For example the risk of increasing the contacts resistance is high due to remnants from grinding paper, etc.

Also lack of cleanliness when attempting to restore the contacts can influence the contactor performance.

Maintenance should be limited to inspection of the contacts for the level of contact wear. This is to ensure a trouble free operation of the contactor until the next service is required.
At the same time observations can be made to judge if the contactor operates well in the application and that no signs of abnormal wear or damages are present on the contacts.

The appearance of contacts after a very low number of operation in an AC-3 application.

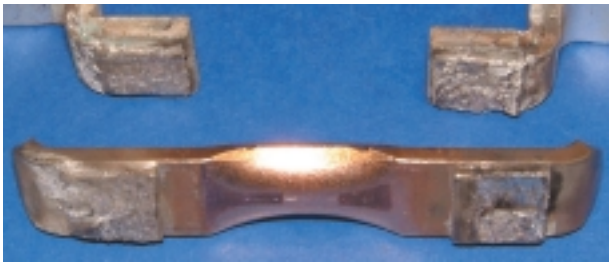
A contact just having reached a ‘good worn in’ level in an AC-3 application.

Interpreting levels of electrical contact wear

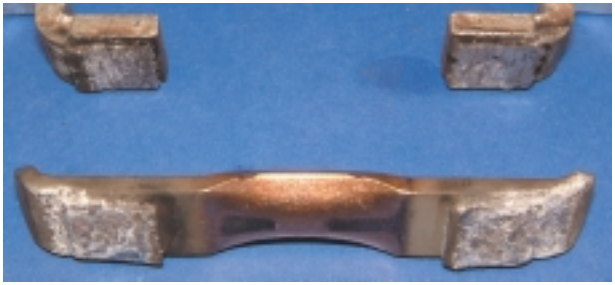
Determining the level of wear on contactors in use is essential from both the functional and economical point of view. Premature service on contactors will increase the overall cost. However, service at the right time to avoid interruptions or breakdowns is more cost effective.

General

The rate of wear is different depending of the utilization category or the application of the contactor. For motor control it also depends on the selected starting method. The following main utilization categories are the most common.



Early stage of fixed and movable contacts in an AC-3 application.



Mid-life stage of fixed and movable contacts in an AC-3 application

End of life of fixed and movable contacts in an AC-3 application

AC-1. (General purpose) Non-inductive or slightly inductive loads, resistance furnaces.

The closing of the main contacts is relatively easy as the starting current is equivalent to the rated current of the load. Breaking is made at full voltage, the arc has a rather low level of energy.

AC-2. Slip-ring motors. Starting, switching off

Typical making and breaking is with approximately 2,5 times the rated current of the motor (Ie x 2.5) the voltage is corresponding to the nominal voltage.

AC-3. Cage motors. Starting, switching off running motors

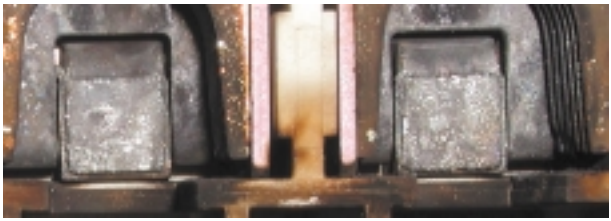
Closing of the main contacts with approximately 6 to 8 times the rated motor current, depending on motor characteristics and type of load.
Breaking is easier, as the current equals the rated motor current, and voltage is reduced to 17 % of the rated voltage.
Typical electrical wear comes from the contact making operation.
Visual inspection of an AC-3 application normally shows none or very little material from the contact tips thrown out into the arc-extinction packages.

AC 4. Cage motors. Starting, plugging, inching.

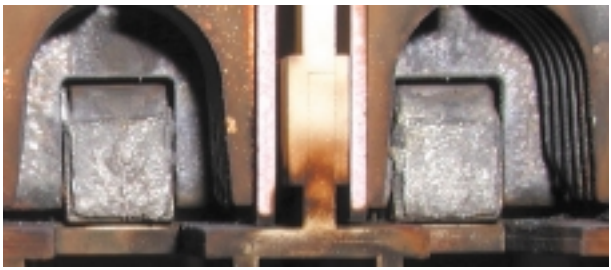
Making and breaking the motor starting current approximately 6 to 8 times the rated motor current. Voltage is not reduced and equals the rated voltage of the motor.

Both making and breaking are contributing to the contact wear. The arc-extinction packages have an important role in extinguishing the arc. Therefore material from the contact tips is in most cases thrown out in the packages. See Figure B on page 5.

Contact wear in AC 4 application, making/breaking locked rotor current



Early stage of fixed (above) and movable contacts (right), 5000 operations.



Mid-life stage of fixed (above) and movable contacts (right) 10000 operations.

End of life.

Changing Contacts

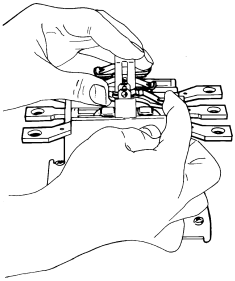
Typical appearance of contacts (Fig. A) and extinction package (Fig B) when breaking locked rotor current (LRC) in an AC-4 application.

Changing contacts on installed units.

EH/ EK Contactors

(1SFC 380002-89)

Replace all of the main contacts at the same time.



EH 100 ... 300

- Remove the arc-chute.
- Press out the moving contacts. Lift the contact somewhat to let the contact easier slide out.
- Exchange the fixed contacts.
- Put in the new moving contacts.

EH 370...800,
EK 370...1000

- Remove the arc-chute.
- Press out the moving arc contacts, see Fig. 1.
- Moving main contacts: Lift the respective clamp and press the contact into neutral position. See Fig. 2. Remove the contacts.
- Exchange the fixed contacts. See Fig. 3.
- Put in the new movable contacts.

Trouble shooting

Some examples of common reasons for excessive contact wear and shortened contact life:

Voltage drop during start up of the motor
Voltage drop to less than 85 % of nominal voltage for 5 to 10 ms can be enough for the contactor to start opening.
Also, other disturbances in the control voltage could be responsible for this problem.
The result of these voltage problems can be increased contact wear and also lead to welding of main contacts.

...related to different starting methods.

DIRECT ON LINE (ACROSS-THE-LINE) MOTOR STARTING

Current peaks due to heavy duty starting

- If the application requires a high level of torque during start-up, for example a fan or a pump, it is important that the contactor's making capacity and short time withstand current are capable of handling the starting current and current peak.

Restarting with motor idling

- Attempting to restart the motor before the motor has come to a full stop will cause a current peak that theoretically can reach twice the current compared to starting the motor from a standstill.
  This can result in welded contacts.

STAR DELTA (WYE-DELTA) STARTERS
Change over time between star and delta.

- Setting the change over time between star and delta too short will not allow the motor to reach 80-90% of its nominal speed. This will cause the star contactor to break a higher current than expected. If the starter stays in the star position for too long of a period; this will increase the stress of the star contactor because the star contactor is mainly sized for the short time current rating.
- The change over time between the star and delta is important. If no timer or other device is used to get an idle time between opening of the star contactor and closing of the delta contactor, there is a risk that the arc inside the star contactor could remain and create a short circuit.

If the elapsed time is too long, the motor starts to decelerate and the delta closing will create a higher current peak than expected. This can result in welded contacts.
Generally the idle time should not exceed 50 ms.

The weather station, type IC1000, is used in wind parks for surveillance and collection of the following data: Wind speed, win direction, temperature, and air pressure.

- The weather station is supplied in a weatherproof GRP-Cabinet IP65.
- The weather station is supplied complete with all standard sensors.
- The mast (pole), is not scope of supply.
- For data collection and stastitics, the weather station communicates with the Mita-Teknik management system.
- The wind speed is measured in the range(0-60)m/s. The primary ultrasonic anemometer is batched by a reference anemometer, mounted at a different level.
- Communication in wind parks with WP3000 controllers.
- The weather station logs wind & weather data and system information, e.g. summary of the latest 31 days in 1 day intervals. 36 hours log for 10 min. mean, max., min. and std. deviation values.
- The wind direction is measured in the range (0-359)°.
- The temperature is measured in the range (-40 - +70.0) °C
- The air pressure is measured in the range (0-200.0)kPa.
- As an option, the weather station is prepared for the connection of ice & lightning detectors, rain sensors, sun sensors etc.
- The weather station is UPS backed.
- The weather station IC1000 (Part no.: 99599018) is produced in accordance with the demands in the DS/EN ISO 9001-standard and is EMC-tested according to EN50082-2 and EN50081-2.

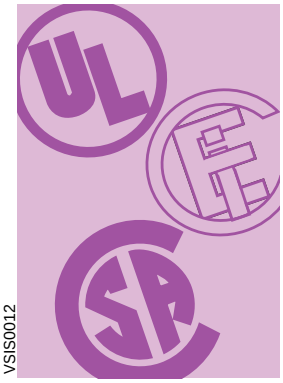
Tecnología, innovación y fiabilidad.
El fruto de la investigación más avanzada

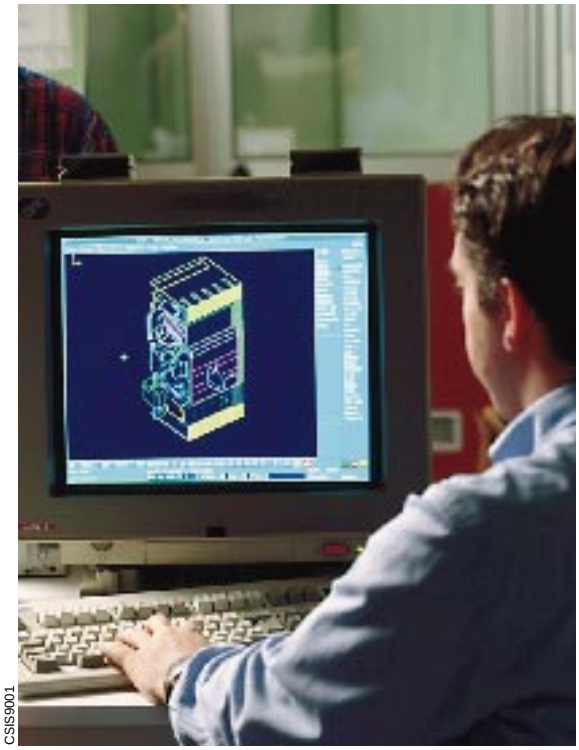


VSIS0012

Siete modelos de interruptores conformes a las normas internacionales IEC 947-2.
SACE Isomax S significa también una gama de interruptores automáticos conformes a las normas estadounidenses UL489 y canadienses CSA 22.2.

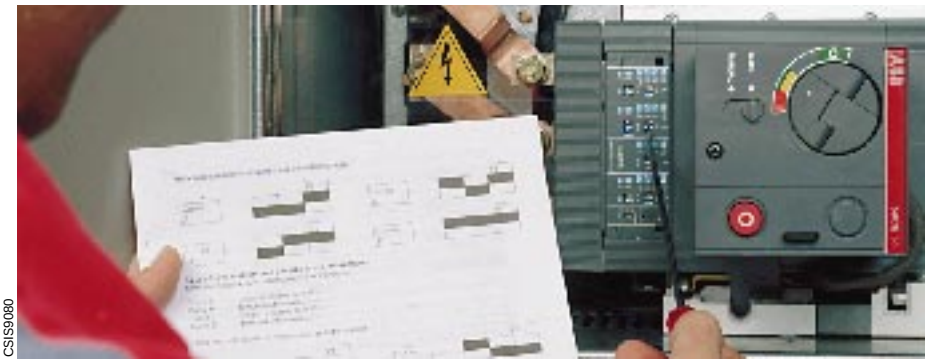
Nueva tecnología para la protección y el control de las instalaciones

La rápida y continua evolución tecnológica ha llevado a un constante aumento de la complejidad de las instalaciones eléctricas; hoy más que nunca las mismas aplicaciones requieren continuidad de servicio, fiabilidad y un número de intervenciones de mantenimiento lo menor posible.
Para que las instalaciones satisfagan estas condiciones son fundamentales los aparatos de protección y, en especial, los interruptores automáticos y diferenciales que, en consecuencia, adquieren un papel fundamental.
Para responder a estas nuevas exigencias de las instalaciones, ABB SACE ha proyectado la nueva serie de interruptores automáticos en caja moldeada de baja tensión SACE Isomax S, que representa un salto generacional en la tecnología del proceso de interrupción de la corriente y, más en general, en la distribución y en el control de la energía eléctrica.
Toda la gama se articula en cinco modelos básicos, S1, S2, S3, S4, S5, S6 y S7, con corrientes permanentes asignadas de 125 a 1600 A y con poder de corte de 16 a 100 kA (380-415 V).



CSIS9001

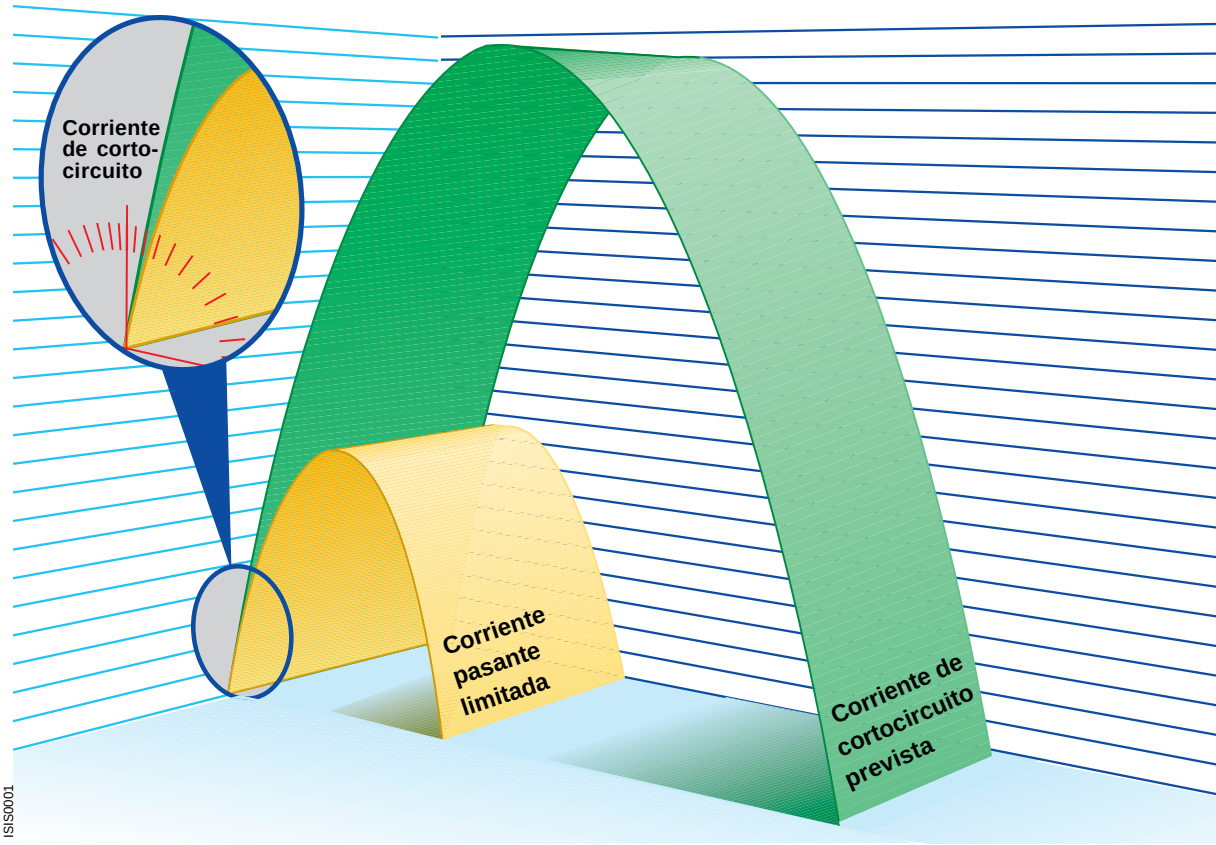
La gama SACE Isomax S, fruto de un atento análisis de las exigencias del mercado, ofrece un alto nivel de prestaciones con unas dimensiones generales especialmente reducidas, flexibilidad, uso práctico, facilidad de instalación y, por lo tanto, un alto nivel tecnológico. En los relés con microprocesador, la parte electrónica, caracterizada por la precisión y la fiabilidad obtenidas gracias a una realización esmerada tanto de los proyectos de los componentes como de los algoritmos de funcionamiento, ha consentido añadir a las tradicionales funciones de protección típicas de los relés termomagnéticos, funciones como el control y la comunicación para obtener una integración completa de los interruptores automáticos con las lógicas de gestión relativas a los sistemas de supervisión y control de la red eléctrica.
Los algoritmos que determinan las funciones de protección se memorizan directamente en el microprocesador del relé. El funcionamiento se controla en los laboratorios de ABB SACE y se basa en la medición del verdadero valor eficaz según criterios de medición, muestreo y reconstrucción de la señal de corriente adecuada a las diferentes condiciones de defecto que se pueden producir en una instalación.
La nueva serie ha sido estudiada de acuerdo con los más modernos criterios ergonómicos como demuestran los premios otorgados a los interruptores automáticos SACE Isomax S en el Forum Design de Hannover y en el Electro de París.
Los interruptores SACE Isomax S se caracterizan por un innovador sistema de corte, alcanzan niveles de seguridad casi totales para el personal encargado de las instalaciones y se realizan completamente con materiales reciclables; esto demuestra que una mayor atención hacia el hombre y el medio ambiente no es incompatible con las eventuales soluciones de los problemas técnicos relacionados con la distribución de la energía eléctrica.



CSIS9080

La mayor velocidad de apertura de los contactos, la acción dinámica de soplado ejercida por el campo magnético y la estructura de la cámara de arco contribuyen a extinguir el arco en el menor tiempo posible con la consiguiente limitación del valor de la energía específica pasante I^2t y del pico de corriente.

CSIS9002
ISIS0001



Corriente alterna y corriente continua. Una única gama para todas las aplicaciones

CSIS9003

La estructura modular en siete modelos, las profundidades coordinadas, los volúmenes reducidos y la variedad de conexiones permiten reducir las dimensiones de los cuadros y simplificar la instalación incluso en cuadros prefabricados.

Mismas posibilidades de aplicación

Los interruptores automáticos SACE Isomax S se pueden utilizar en todas las instalaciones industriales y civiles para la producción y la distribución de energía eléctrica en corriente alterna con corrientes de servicio de 10 a 1600 A y en corriente continua de 10 a 800 A. Por lo tanto, se aplican en los cuadros de distribución primaria (Power Center) y secundaria (Panel Board) para la protección y el mando de motores (Motor Control Center), generadores y usuarios finales. Sin embargo, las prestaciones son especialmente interesantes cuando se presentan situaciones críticas (corrientes nominales y de defecto muy elevadas) o cuando se necesitan instalaciones complejas (exigencias especiales de coordinación y automatización de las instalaciones). Además, la amplitud de la gama y las posibilidades de empleo están garantizadas por la presencia de una serie de accesorios completa y flexible, idénticos para los grupos de interruptores S1-S2/S3-S4-S5/S6-S7. Esto consiente satisfacer cualquier tipo de exigencia, racionalizar el almacén y reducir las reservas necesarias.

VSIS0003

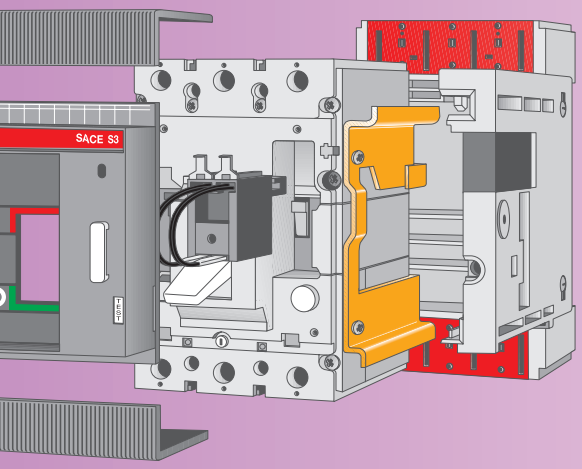
Las aplicaciones de corriente continua y de corriente alterna consienten satisfacer todas las exigencias de distribución, protección y control de los dispositivos de la instalación, desde los cables hasta las máquinas.

Funcionalidad y seguridad para los usuarios finales

Los interruptores automáticos, diferenciales, de maniobra-seccionadores de la serie SACE Isomax S han sido proyectados de manera que todas las personas que los utilizan (instaladores, operadores y encargados del mantenimiento) trabajen en plena seguridad gracias a algunas características especiales como:

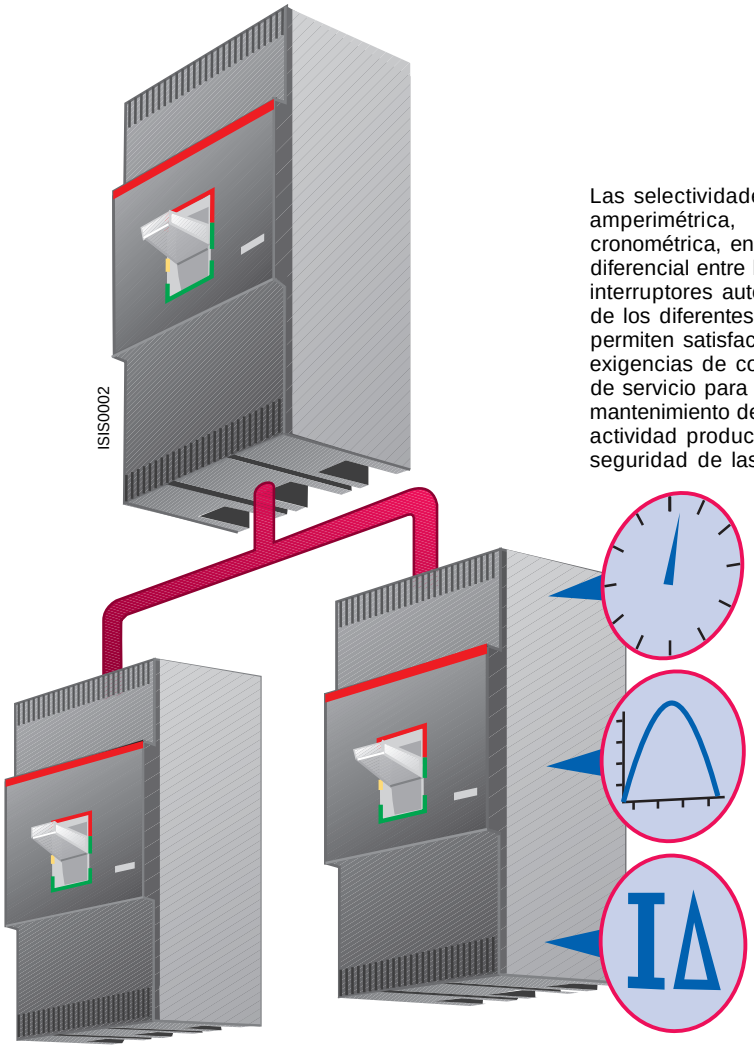
- **doble aislamiento**
- **bloqueo de la puerta de la celda con interruptor cerrado**
- **posibilidad de extraer el interruptor con la puerta de la celda cerrada**
- **seccionamiento de los circuitos auxiliares de los accesorios para las versiones enchufables y extraíbles**
- **maniobra positiva gracias a la cual se tiene la certeza de que la posición de la palanca (interruptor abierto o cerrado) corresponde exactamente a la posición de los contactos del interruptor**
- **facilidad de inspeccionar el interruptor con lo que es posible efectuar el correcto mantenimiento y reducir los tiempos de intervención y los paros de la instalación.**

Para satisfacer de la mejor manera cualquier exigencia de la red de distribución, los nuevos interruptores automáticos unen, a las tradicionales funciones de protección, la coordinación selectiva, la protección de tierra, la medición y la transmisión de los datos y la posibilidad de la gestión centralizada.



Los interruptores automáticos con corrientes asignadas de 10 a 1600 A de corriente alterna pueden combinarse con relés diferenciales que funcionen con una tensión asignada de servicio a partir de 50 V. Esto garantiza la seguridad continua de la instalación incluso en condiciones de funcionamiento crítico debido a bajadas de tensión por defectos de alimentación; en estas circunstancias, la protección diferencial contra contactos indirectos y riesgos de incendio por pérdida de los aislamientos permanece activada.

Los relés diferenciales pueden usarse para corrientes de fuga a tierra de 0,03 a 30 A con actuación retardable hasta 5 s y se pueden aplicar a todos los interruptores automáticos de la serie SACE Isomax S; es posible elegir entre los relés diferenciales SACE RC211 o RC212 (para montar directamente en versión lateral o vertical a los interruptores S1, S2 y S3) y el relé diferencial de cuadro SACE RCQ (utilizable con todos los interruptores).



Las selectividades amperimétrica, cronométrica, energética y diferencial entre los interruptores automáticos de los diferentes modelos permiten satisfacer las exigencias de continuidad de servicio para el mantenimiento de la actividad productiva y la seguridad de las personas.

Dimensionamiento óptimo, versatilidad en la aplicación. La mejor relación entre las prestaciones y los costes

Múltiples soluciones para proyectar las instalaciones

Con los interruptores automáticos SACE Isomax S el proyectista dispone de una amplia gama de soluciones que le permiten dimensionar adecuadamente cualquier tipo de instalación, tanto desde un punto de vista técnico como económico.

La tipología de los interruptores comprende:

- **Interruptores automáticos en versión fija, enchufable y extraíble, con cinco niveles de poder de corte de 16 a 100 kA, identificados por las siglas B, N, S, H y L**
- **Interruptores de maniobra-seccionadores**
- **Interruptores automáticos diferenciales**
- **Interruptores diferenciales**
- **Interruptores para proteger los motores con relés solo magnéticos**
- **Interruptores para máquinas herramienta**
- **Interruptores para ambientes marinos o tropicales**
- **Componentes de la serie SACE SD para la integración en sistemas de supervisión y control.**

La variedad de las versiones es fruto de la combinación de las ejecuciones disponibles y de la posibilidad de elegir entre diferentes tipos de relés (termomagnéticos o electrónicos con microprocesador) de manera que se puedan satisfacer todas las exigencias de aplicación. La elección del modelo permite identificar las características eléctricas fundamentales (corrientes asignadas y poder de corte), la elección del relé, el tipo de aplicación (corriente alterna, corriente continua, protección contra la sobrecarga, cortocircuito, defecto a tierra, comunicación y supervisión).

Tipo	Iu (40 °C)	Ue [V]		Categoría	Relé	Icu (380 - 415 V c.a.)

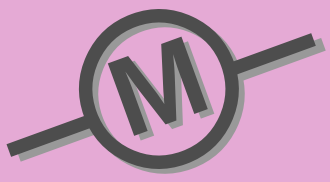
S7 1250	1250 A	690	–	B	µP				S	H		L
S7 1600	1600 A	690	–	B	µP				S	H		L

TM = Relés de sobrecorriente termomagnéticos
µP = Relés de sobrecorriente con microprocesador

Interruptores automáticos para corriente continua

Los interruptores automáticos para corriente continua con relés termomagnéticos se encuentran disponibles para tensiones de servicio hasta 750 Vcc (con 3 polos en serie) y para corrientes de servicio de 10 a 800 A. La conexión en serie de los polos consiente realizar aplicaciones en condiciones de uso más difíciles y en cualquier tipo de red (aislada, con polaridad a tierra y con punto medio de la alimentación a tierra).

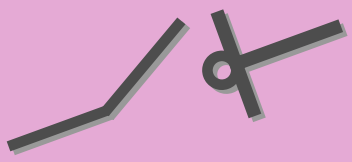


Interruptores automáticos para la protección de motores

Son ideales para la protección y la maniobra de motores para potencias hasta 355 kW, alcanzando un nivel de coordinación “tipo 2” con arrancadores ABB.
El arrancador se compone de diferentes dispositivos según si el interruptor automático realiza funciones de maniobra, protección contra el cortocircuito o contra la sobrecarga.

Interruptores automáticos para el mando de máquinas herramienta

Las versiones con corrientes asignadas de 32 a 400 A se encuentran disponibles en ejecución para el mando y el control de máquinas herramienta, incluso de elevada potencia. Concretamente, la ejecución con mando giratorio en el interruptor, relé de mínima tensión y contacto auxiliar anticipado (que mantiene desexcitado el relé de mínima con el interruptor automático abierto) ha sido estudiada para cumplir con las normas IEC 204-1, CEI 44-5 y VDE 0113.

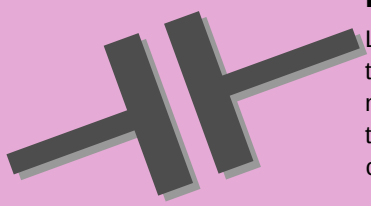


Interruptores de maniobra-seccionadores

Los interruptores de maniobra-seccionadores derivan de los correspondientes interruptores automáticos de los cuales conservan inalteradas las dimensiones generales, las ejecuciones y los accesorios. El dispositivo de disparo puede ser accionado por el relé de mínima tensión o por el relé de apertura. También se pueden dotar con relés diferenciales.

Interruptores automáticos para la protección de generadores

La corriente de cortocircuito permanente, en caso de defecto aguas abajo de un generador, depende de la impedancia síncrona de la máquina y, en general, es ligeramente superior a la corriente asignada del generador. Por este motivo, es necesario utilizar interruptores automáticos con un umbral de actuación instantáneo bajo, disponibles en las versiones con relé electrónico con microprocesador.



Interruptores automáticos para la protección de condensadores

La maniobra de conexión de una batería de condensadores puede provocar una sobrecorriente transitoria, incluso de gran intensidad. Gracias a los elevados poderes de cierre, a la larga durabilidad mecánica y eléctrica y al amplio campo de regulación de los diferentes parámetros, los interruptores automáticos SACE Isomax S están especialmente indicados para la maniobra y la protección de las baterías de condensadores.

Sistemas centralizados de supervisión y control

La fiabilidad, la eficiencia y la calidad del servicio de distribución de la energía eléctrica en baja tensión están considerablemente reforzadas gracias a una continua supervisión de los servicios y de todos los parámetros de la misma instalación, de manera que ha sido posible añadir nuevas oportunidades, como la actualización en tiempo real del estado de conexión de la red, el mando remoto de los interruptores de maniobra-seccionadores, la recogida de datos sobre el servicio de la red, el mantenimiento preventivo, la reconstrucción o nivel de gestión de la situación de la instalación, la gestión integrada de la red de distribución de la energía eléctrica. Las informaciones sobre la instalación se recogen mediante componentes de campo con microprocesadores que pueden montarse directamente en los aparatos, como el relé SACE PR212/P, o mediante dispositivos capaces de adquirir magnitudes analógicas y/o digitales significativas para el control de la instalación, como los dispositivos de la familia SACE SD. Además, el uso del software SACE SD-View 810 consiente transformar un simple ordenador personal en una estación para la supervisión y el control de las instalaciones de distribución de energía eléctrica.

Una elección guiada...
.....para una fácil instalación

Elaboración de proyectos y dimensionamiento de las instalaciones eléctricas

Se encuentran disponibles cinco instrumentos de trabajo muy útiles (el software DOC, el kit de reglas, la guía para la selección de aparamenta de baja tensión, el catálogo electrónico C.A.T. y el software INSINT) que facilitan los cálculos, aseguran la conformidad del equipo con las normativas y disminuyen los riesgos de error.

CSIS9004

El software DOC permite que el proyectista realice, en poco tiempo, un correcto dimensionamiento técnico y económico utilizando los equipos ABB.
Asimismo, dicho software permite que el proyectista desarrolle una documentación del proyecto clara y completa sobre las bases de los modelos de cálculo previstos por las normativas y de los datos experimentales deducidos en las pruebas sobre los componentes.

CSIS9005

Cuatro reglas de diferente color, que constituyen el kit ABB, permiten rápidos cálculos de dimensionamiento del equipo eléctrico según los métodos deducidos de las vigentes normas UNE, IEC y de la práctica en el sector. Es posible efectuar:
– El dimensionamiento de los cables y el cálculo de las corrientes de cortocircuito (regla amarilla).
– La Verificación de las protecciones contra los contactos directos y de cortocircuito de los cables (regla naranja).
– La coordinación selectiva y de acompañamiento (regla verde).
– El dimensionamiento de las líneas de motor y salidas de los transformadores (regla azul).

CSIS9006

La Guía para la selección de aparamenta de baja tensión permite el cálculo de la instalación y la optimización técnica y económica en la selección de la aparamenta.
Constituye una herramienta de consulta práctica e imprescindible para proyectistas e instaladores.

CSIS9007

Para facilitar la elección de los interruptores se encuentra disponible el **catálogo electrónico multimedia C.A.T.** (**C**omputer **A**ided **T**echnical selection) en CD-ROM, con el cual es posible, mediante unos recorridos guiados, seleccionar y solicitar directamente el interruptor más adecuado a las exigencias de la instalación y elaborar una documentación técnico-comercial personalizada sobre los productos formada por fichas técnicas, curvas de actuación, dimensiones, pedido, etc., todo ello impreso o en un fichero.
INSINT, instrumento disponible en disquetes en el cual se recogen, en formato “dxf” y “dwg”, los planos de dimensiones de los interruptores en las varias ejecuciones, disponibles ya en el CD-ROM del C.A.T.

Racionalización constructiva

Las características constructivas de los nuevos interruptores automáticos simplifican considerablemente la instalación y la conexión.
Los criterios de elaboración del proyecto y los nuevos materiales utilizados han permitido mejorar la relación entre el poder de corte y el volumen del interruptor automático.
En consecuencia, y gracias también a las características de los interruptores - modularidad en 7 modelos, profundidades coordinadas, volúmenes reducidos y marco común (de S1 a S5 para ventana de 45 mm o de S3 a S7 para ventana de 105 mm) - ha sido posible reducir especialmente las dimensiones de los cuadros.

A partir del modelo S3, los accesorios se pueden montar directamente por la parte frontal; unos huecos especiales realizados de acuerdo con el perfil de los accesorios facilitan la inserción. No se requieren regulaciones y, en ningún caso, es necesario quitar la tapa del interruptor, gracias a la cual se garantiza el doble aislamiento y, por lo tanto, el mejoramiento de las condiciones de seguridad del operador en la gestión y la inspección de las instalaciones. Para los interruptores S1 y S2, los accesorios se fijan a la tapa del interruptor.
Además, la diversificada gama de terminales disponibles hace que los interruptores SACE Isomax S sean adecuados para cualquier tipo de conexión (superiores de un tipo e inferiores de tipo diferente), para la mayor flexibilidad de instalación.

CSIS9008

Normas, homologaciones, certificados y sistemas de calidad empresarial

Los interruptores automáticos SACE Isomax S y sus accesorios responden a las normas internacionales IEC 947-2, EN 60947-2 (armonizadas en 17 países del CENELEC), UNE EN 60947 e IEC 1000 y son conformes a las directivas CE:

– "Low Voltage Directives" (LVD) nº 73/23 EEC.
– "Electromagnetic Compatibility Directive" (EMC) nº 89/336 EEC.

Los certificados de conformidad con las normativas de productos anteriormente mencionadas, son expedidos, según lo establecido por la norma europea EN 45011, por el organismo de certificación italiano ACAE (Associazione per la Certificazione delle Apparecchiature Elettriche), reconocido por el instituto europeo LOVAG (Low Voltage Agreement Group).

El Sistema de Calidad ABB SACE es conforme a la norma internacional ISO 9001 (modelo para asegurar la calidad durante la elaboración de proyectos, desarrollo, fabricación, instalación y asistencia) y a las equivalentes normas europeas EN ISO 9001 e italianas UNI EN ISO 9001.

El tercer instituto de certificación es el RINA-QUACER.

ABB SACE ha obtenido, en 1990, el primer certificado con validez trienal y, en la actualidad, ha obtenido la tercera reconfirmación.

Los equipos son conformes a cuanto dispuesto por las normativas para las instalaciones en bugues y han sido homologados por los registros navales indicados al lado.

CSIS9009

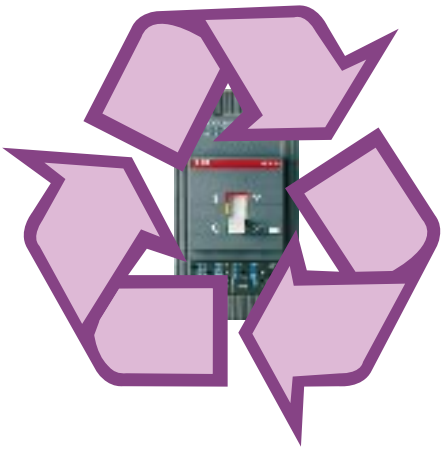
CSIS9098

CSIS9099

ISO 9001

La atención por la salvaguardia del medio ambiente es otra cuestión prioritaria para ABB SACE como demuestra el hecho de que el sistema de gestión medio-ambiental ha obtenido la certificación del instituto RINA. ABB SACE, primera industria del sector electromecánico que en Italia ha obtenido este reconocimiento, ha reducido un 20% el consumo de materias primas y de residuos creados durante la fabricación gracias a una revisión del proceso productivo desde un punto de vista ecológico.

El empeño de ABB SACE en la protección del medio ambiente se concretiza también en las evaluaciones del ciclo de vida de los productos (LCA, del inglés Life Cycle Assessment), realizadas en el Centro de Investigación. La selección de los materiales, de los procesos y de los embalajes se ha efectuado con miras a reducir el impacto real del producto en el medio ambiente y prever la eficacia energética y su reciclabilidad.



CSIS9010

Un producto flexible para una gestión fácil. Servicio y asesoramiento para cualquier exigencia

Pedidos inmediatos y gestión flexible

Para los interruptores automáticos de la serie SACE Isomax S se han previsto unos procedimientos de realización de pedidos muy rápidos; además, la lógica según la cual se ha configurado la serie, permite gestionar los almacenes de manera eficiente y flexible.
Es posible generar un fichero de pedido compatible con el sistema EDIFACT (Metel o ABB), listo para convertirse en formato EDI y enviarse electrónicamente. El uso del EDI (Electronic Data Interchange) para el envío del pedido, racionaliza la cadena logística y reduce los tiempos de transmisión y los riesgos de error. El envío mediante EDI permite la carga automática del pedido en ABB SACE con el envío inmediato al departamento de producción y la confirmación del pedido al cliente.
Para facilitar la realización de los pedidos se encuentran disponibles tanto los códigos correspondientes al interruptor ensamblado como los códigos correspondientes a los accesorios o kits de componentes. La disponibilidad de los accesorios unificados por grupos de interruptores permite reducir la cantidad en el almacén y los tiempos de aprovisionamiento muy breves permiten limitar los stocks ya que se pueden restablecer con facilidad.

La formación: un instrumento indispensable para los profesionales

ABB SACE, empresa del sector distribución del grupo ABB, desea poner a disposición de los profesionales su experiencia, acumulada en más de 60 años de actividad, mediante cursos de formación técnica que, realizados por expertos, representen una oportunidad para la puesta al día y el enriquecimiento.
La información y la formación son siempre factores de éxito para el crecimiento y el desarrollo profesional. La puesta al día profesional, tanto desde un punto de vista técnico y del producto como de un punto de vista normativo y legislativo, es indispensable debido a las notables implicaciones para la seguridad de las personas y de las instalaciones. El primer objetivo de los cursos es, precisamente, responder a las exigencias de información de los profesionales, sobre todo, convirtiendo los conceptos técnicos y normativos-legislativos en términos prácticos que se puedan aplicar directamente a los diferentes productos e instalaciones.

CSIS9081

CSIS9082

El “Servicio ABB SACE”

También existen cursos de formación cuyo objetivo es la preparación del personal de servicio y de mantenimiento que trabaja en los interruptores y los sistemas ABB SACE.
Con este objetivo, la empresa, en respuesta a las exigencias de adecuación y mantenimiento de las instalaciones eléctricas existentes, dispone de una “Division Service” en su estructura que se propone como interlocutor cualificado para desarrollar, en estrecha colaboración con los gestores y usuarios de las instalaciones, actividades de mantenimiento, reparación y revisión en la sede de ABB SACE y en los locales del usuario, servicio de recambios y montaje y puesta en servicio de cuadros de construcción propia.

Notas

1) Todas las versiones con Icu=35kA están certificadas para 36kA.
2) Para interruptores S3 N/H/L, S4 N/H/L, S5 N/H y S6 N/S/H, la prestación porcentual de Ics a 690V se reduce un 25%.
3) Los interruptores en versión extraíble se suministran con el frontal para el mando por palanca o con los accesorios alternativos a éste como, por ejemplo, el mando giratorio o el mando motor.
4) Para el interruptor S5, la versión enchufable se encuentra disponible solamente para la corriente asignada de 400A (S5 N/H/L/ 400).
5) El interruptor SACE S3 con poder de corte L a 690V sólo se puede alimentar desde la parte superior.

Las versiones

Los interruptores de maniobra-seccionadores son de tres tipos: S3D, S6D y S7D y derivan de los correspondientes interruptores básicos, a saber:

- Los interruptores S3D 100-160-250-320 A derivan del interruptor básico S3N250
- Los interruptores S6D 400-630-800 A derivan del interruptor básico S6N630
- Los interruptores S7D 1000-1250-1600 A derivan del interruptor básico S7S1250.

En su campo de empleo, estos interruptores son verdaderos interruptores de maniobra-seccionadores ya que no se ha previsto ningún disparo directo para ningún nivel de corriente que los atraviese durante su uso.

La protección

Tienen que estar protegidos por interruptores automáticos instalados aguas arriba o formar parte de un conjunto en el cual se hayan instalado dispositivos de protección coordinados con los mismos. Cada interruptor de maniobra-seccionador SACE Isomax está protegido a condición de que aguas arriba del mismo haya un interruptor automático SACE Isomax de características adecuadas o inferiores a las del interruptor del cual deriva y hasta el máximo poder de corte del nivel H. Por ejemplo, un interruptor de maniobra-seccionador de tipo S3D está protegido si hay un interruptor S3H, S3N, S2B-N-S o S1B-N aguas arriba. En caso de cortocircuito, la actuación del interruptor automático situado aguas arriba garantiza la protección (backup) del interruptor de maniobra-seccionador situado aguas abajo.

Las funciones

Los interruptores de maniobra-seccionadores se emplean principalmente como interruptores generales de subcuadros, como órganos de maniobra y seccionamiento de líneas, de barras o de conjuntos de maniobra, como un acoplador de barras o en un conjunto de maniobra y protección de un motor. Los interruptores de maniobra-seccionadores pueden efectuar y garantizar:

- la maniobra de las corrientes en condiciones normales del circuito: cierre, conducción y corte;
- el seccionamiento del circuito: con la palanca en posición de abierto, se tiene la certeza de que todos los polos se encuentran en la posición de abierto (maniobra positiva) y las distancias de aislamiento son las adecuadas para no favorecer el cebado del arco, en conformidad con las normas IEC 947 sobre la aptitud al seccionamiento;
- el cierre en específicos valores de cresta de corriente de cortocircuito, poder de cierre Icm:
  - S3D: 10 kA
  - S6D: 30 kA
  - S7D: 52,5 kA.

  El poder de cierre es muy importante para la seguridad ya que un aparato de maniobra ha de poder soportar, sin destruirse, las solicitaciones dinámicas, térmicas y de corriente que pueden producirse durante el cierre, hasta las condiciones de cierre en cortocircuito.
- la capacidad de soportar en posición de cerrado la corriente asignada de corta duración admisible I_{cw} durante 1 segundo:
  - S3D: 6,5 kA
  - S6D: 15 kA
  - S7D: 25 kA.

La maniobra de apertura o cierre es de tipo independiente con actuación rápida, para que la velocidad y la fuerza de la maniobra sean independientes de la fuerza ejercida por el operador.

Accesorios y aplicaciones

En los interruptores de maniobra-seccionadores se pueden realizar en todas las versiones y aplicaciones de los correspondientes interruptores de los que derivan.

El dispositivo de disparo puede ser accionado por el relé de mínima tensión o por la bobina de apertura. El interruptor S3D también se puede equipar con los relés diferenciales SACE RC211/3 - RC212/3. Los interruptores de maniobra-seccionadores conservan inalteradas las dimensiones generales, las ejecuciones, los sistemas de fijación y la posibilidad de incorporar los accesorios de los interruptores automáticos de los cuales derivan.

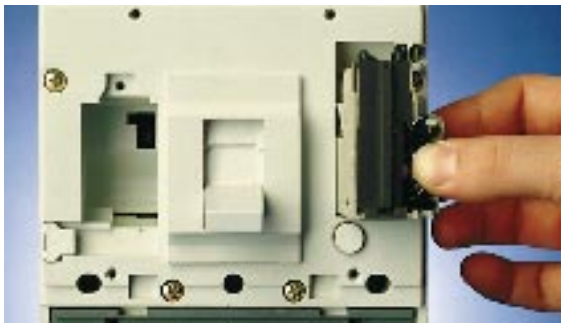
Los interruptores SACE Isomax S, conformes a las normas UL489 y CSA 22.2 se pueden pedir mediante unos códigos especiales que suministra ABB SACE. La conformidad con las normas indicadas está certificada y declarada en la etiqueta de las prestaciones. La gama se compone de interruptores automáticos en caja moldeada, interruptores automáticos con relés exclusivamente magnéticos (Motor Control Protection - MCP) e interruptores de maniobra (Molded Case Switch - MCS).
Los interruptores se suministran en ejecución fija con terminales anteriores para cables de cobre-aluminio y se encuentran disponibles, con la correspondiente certificación, los siguientes accesorios:

– relé de mínima tensión y correspondiente conector
– relé de apertura y correspondiente conector
– contactos auxiliares y correspondiente conector
– mando a motor (de acción directa y por acumulación de energía) y correspondiente conector
– mando giratorio
– frontal para mando por palanca
– cubrebornes y tornillos precintables
– unidad “Trip test” para relés con microprocesador.

Para mayor información, ponerse en contacto con el distribuidor local.

Características constructivas



CSIS9027

Doble aislamiento

La técnica del doble aislamiento consiste en la separación total entre los circuitos de potencia y los auxiliares y caracteriza todos los interruptores automáticos SACE Isomax S a partir del tamaño S3. La sede de cada accesorio eléctrico está completamente segregada del circuito de potencia; de esta manera, se evita todo riesgo de contacto con las partes activas y se aumenta, así, las condiciones de seguridad del operador en la gestión y la inspección de las instalaciones.
Entre las partes activas interiores, el interruptor automático presenta, además, un aislamiento redundante, tanto por el espesor de los materiales como por las distancias, superiores a las requeridas por las Normas IEC y conformes a cuanto previsto por los estándares estadounidenses.

CSIS9028

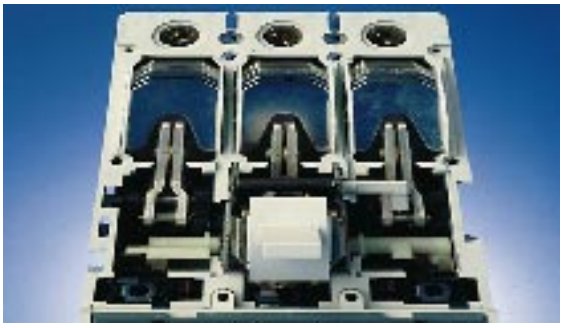
Maniobra positiva

La palanca de maniobra indica siempre la posición precisa de los contactos móviles del interruptor automático garantizando, así, unas señalizaciones seguras y fiables (I = Cerrado; O = Abierto; *línea amarilla* = Abierto por actuación de los relés). El mecanismo del mando del interruptor es de disparo libre independiente de la presión sobre la palanca y de la velocidad de la operación. La actuación de los relés abre automáticamente los contactos móviles: para cerrarlos hay que rearmar el mando, empujando la palanca de maniobra desde la posición intermedia hasta la extrema inferior de abierto.
Para interruptores enchufables o extraíbles, la separación de la parte móvil de la parte fija solamente puede efectuarse con el interruptor abierto (contactos móviles separados de los contactos fijos).

ISIS0016

Selectividad

La completa gama de relés disponibles permite coordinar las funciones de protección de los interruptores automáticos según cadenas de selectividad de tipo amperimétrico, cronométrico, energético o diferencial. De esta manera es posible aislar sólo la zona del defecto y asegurar la máxima continuidad de servicio. Los interruptores automáticos de categoría B se encuentran disponibles a partir de 400 A de corriente permanente asignada.



CSIS9029

Facilidad de control

Con el interruptor fuera de servicio es posible controlar directamente el estado de las piezas interiores y de los componentes activos del interruptor. Las cámaras de arco y los contactos fijos y móviles son accesibles tras quitar simplemente la tapa del interruptor. Esta operación, facilitada por el número limitado de componentes, reduce los tiempos de mantenimiento y garantiza un nivel superior de seguridad.

CSIS9030

Aptitud al seccionamiento

En la posición de abierto, el interruptor automático garantiza el seccionamiento del circuito en conformidad con la Norma IEC 947-2. Para interruptores extraíbles o enchufables, en posición de extraído o removido, los circuitos de potencia y auxiliares se encuentran aislados, para garantizar que ninguna parte se encuentre bajo tensión. En estas condiciones es posible efectuar, mediante los correspondientes conectores, pruebas en blanco y maniobrar el interruptor con plena seguridad. Las distancias de aislamiento redundantes garantizan la ausencia de corrientes de fuga y la rigidez dieléctrica a eventuales sobretensiones entre entrada y salida.

CSIS9031

Extracción con la puerta cerrada

Este sistema, presente por primera vez en una serie de interruptores automáticos en caja moldeada, a partir de 160 A, permite insertar y extraer el interruptor con la puerta de la celda cerrada, aumentando la seguridad del operador y permitiendo realizar cuadros de baja tensión a prueba de arco interno. La extracción se puede efectuar sólo con el interruptor abierto, utilizando una manivela de extracción suministrada con el interruptor en ejecución extraíble.

CSIS9109

Compatibilidad electromagnética

Con el uso de los relés de sobreintensidad con microprocesador SACE PR211/P y PR212/P y de los relés electrónicos diferenciales SACE RC211 y RC212 se garantiza la ausencia de intervenciones intempestivas incluso bajo la presencia de interferencias provocadas por aparatos electrónicos, perturbaciones atmosféricas o descargas de naturaleza eléctrica. Además, no se generan interferencias a otros aparatos electrónicos cerca de la instalación . Todo ello, en conformidad con las normativas IEC 947 - 2 Apéndice F, IEC 1000-4, EN 61000-4, EN 50081-2, Directiva Europea Nº 49/12-12-1992 sobre la compatibilidad electromagnética - EMC.

CSIS9110

Tropicalización

Todos los interruptores automáticos y accesorios de la serie SACE Isomax S respetan las más severas prescripciones para el uso en un clima cálido-húmedo-salino (conformidad al climatograma 8 de las normas IEC 721-2-1) gracias a:

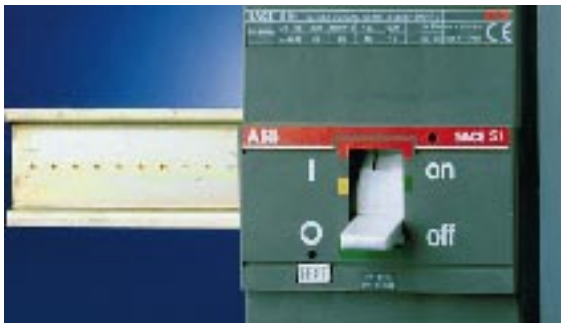
- Cajas aislantes de resinas sintéticas reforzadas con fibra de vidrio.
- Tratamiento anticorrosivo en las partes principales metálicas (ambiente C - UNI 3564-65).
- Cincado Fe/Zn 12 (UNI ISO 2081) protegido por una capa de conversión formada, prevalentemente, por cromados (UNI ISO 4520).

Características constructivas

CSIS9112

Grados de protección

En los interruptores automáticos SACE Isomax S se han adoptado diversas soluciones para alcanzar el grado de protección IP20, para el interruptor en ejecución fija, enchufable y extraíble, salvo los terminales, e IP30 para las partes frontales de los interruptores instalados en el cuadro.
Las partes fijas siempre están predispuestas con grado de protección IP20. Es posible alcanzar el grado de protección IP54 con el interruptor instalado en cuadro utilizando el mando giratorio reenviado a la puerta de la celda y el correspondiente accesorio para protección IP54 que se pueden pedir por separado.



CSIS9033

Montaje sobre guía DIN hasta 630 A

Los accesorios de fijación a los perfiles normalizados DIN EN 50022 para S1 y S2 y DIN EN 50023 para S3, S4 y S5 simplifican el montaje de los interruptores automáticos hasta 630 A en cuadros estándares. Esto permite disponer de estructuras de soporte normalizadas y simplifica la fase de elaboración de proyecto y de realización de la carpintería del cuadro

CSIS9111

Resistencia a las vibraciones

Los interruptores son insensibles a las vibraciones generadas mecánicamente o por efecto electromagnético en conformidad con las normas IEC 68-2-6 y a los estándares más severos de las entidades de clasificación:
– RINA
– DET Norske Veritas
– Lloyd's Register of Shipping
– Germanischer Lloyd
– Bureau Veritas.

CSIS9035

Posiciones de instalación

Las características asignadas del interruptor no varían sea cual sea la posición de instalación. En conformidad a las Normas IEC 947-2, los interruptores automáticos SACE Isomax S se pueden alimentar indiferentemente mediante los terminales superiores o inferiores sin perjudicar la funcionalidad del aparato.
Se pueden instalar en cuadros, directamente montados en la placa de fondo o en la guía DIN hasta el modelo S5.

CSIS9101

Ejecuciones y terminales de conexión

Los interruptores automáticos SACE Isomax S están formados por una caja aislante que sirve de estructura portante realizada con material vitro-poliéster que garantiza la indeformabilidad incluso en las condiciones más severas de cortocircuito. El disparo de los contactos móviles es libre y consiente que éstos retornen y permanezcan en la posición de abierto cuando la apertura está provocada por los relés de sobreintensidad, y también después del inicio del cierre del interruptor automático o bien en caso de que la palanca del mando de cierre se mantenga por fuerza. La acción de disparo es simultánea para todos los polos del interruptor automático.
Toda la gama se realiza solamente en 3 profundidades:
– 70 mm para S1 y S2 (10-160 A);
– 103,5 mm para S3, S4, S5 y S6 (32-800 A);
– 138, 5 mm para S7 (400-1600 A).
con lo cual es posible realizar cuadros con celdas adecuadas a varios interruptores y la fijación en la placa de fondo a la misma cota.

La parte frontal de los interruptores ha sido normalizada por grupos:
– H = 45 mm para S1, S2, S3, S4 y S5 (10-630 A)
– H = 105 mm para S3, S4, S5, S6 y S7 (32-1600 A)
con lo que se consigue obtener notables ventajas en cuanto a la normalización de los cuadros.
El interruptor en ejecución fija, tripolar o tretrapolar prevé:
– los terminales superiores e inferiores iguales, del tipo anterior para cables de cobre para S1 y S2 (con diafragmas separadores) y del tipo anterior para conexión en barra para S3, S4, S5, S6 y S7;
– el mando por palanca;
– el relé de sobreintensidad, termomagnético para S1, S2, S3, S5 y S6 o bien electrónico con microprocesador para S4, S5, S6 y S7;
– el marco para la puerta del cuadro.

Los interruptores automáticos SACE Isomax S están disponibles en ejecución FIJA, ENCHUFABLE o EXTRAÍBLE, tripolar o tetrapolar.

CSIS9036

F
FIJO

CSIS9037

P
ENCHUFABLE

CSIS9038

W
EXTRAÍBLE

El interruptor en ejecución ENCHUFABLE se compone de:
– parte fija que se tiene que instalar directamente en la placa de fondo de compartimiento;
– parte móvil obtenida del interruptor fijo con el añadido de los contactos de seccionamiento en correspondencia de los terminales de conexión, de la estructura metálica posterior para la fijación a la parte fija y de los cubre bornes.

La remoción del interruptor se efectúa desenroscando los tornillos de fijación superiores e inferiores. Un bloqueo impide la inserción y la remoción del interruptor automático con los contactos en posición de cerrado.

Interruptor	F Fijo	P Enchufable	W Extraíble

S6 800	■	–	■
S7 1250	■	–	■
S7 1600	■	–	■

El interruptor en ejecución EXTRAÍBLE se compone de:
– parte fija que se tiene que instalar directamente en la placa de fondo de compartimiento o bien en el perfil (hasta S5), con el grupo guía lateral montado en la parte fija para consentir el movimiento de extracción/inserción;
– parte móvil obtenida del interruptor fijo con el añadido de los contactos de seccionamiento en correspondencia de los terminales de conexión, de la estructura metálica posterior (que se acopla al lateral previsto en la parte fija para el deslizamiento) y de los cubre-bornes.
– accesorio que se tiene que aplicar en la parte frontal del interruptor, a elegir entre frontal para mando por palanca, mando a motor y mando giratorio; la aplicación de uno de estos accesorios consiente realizar el bloqueo del interruptor en posición de extraído.

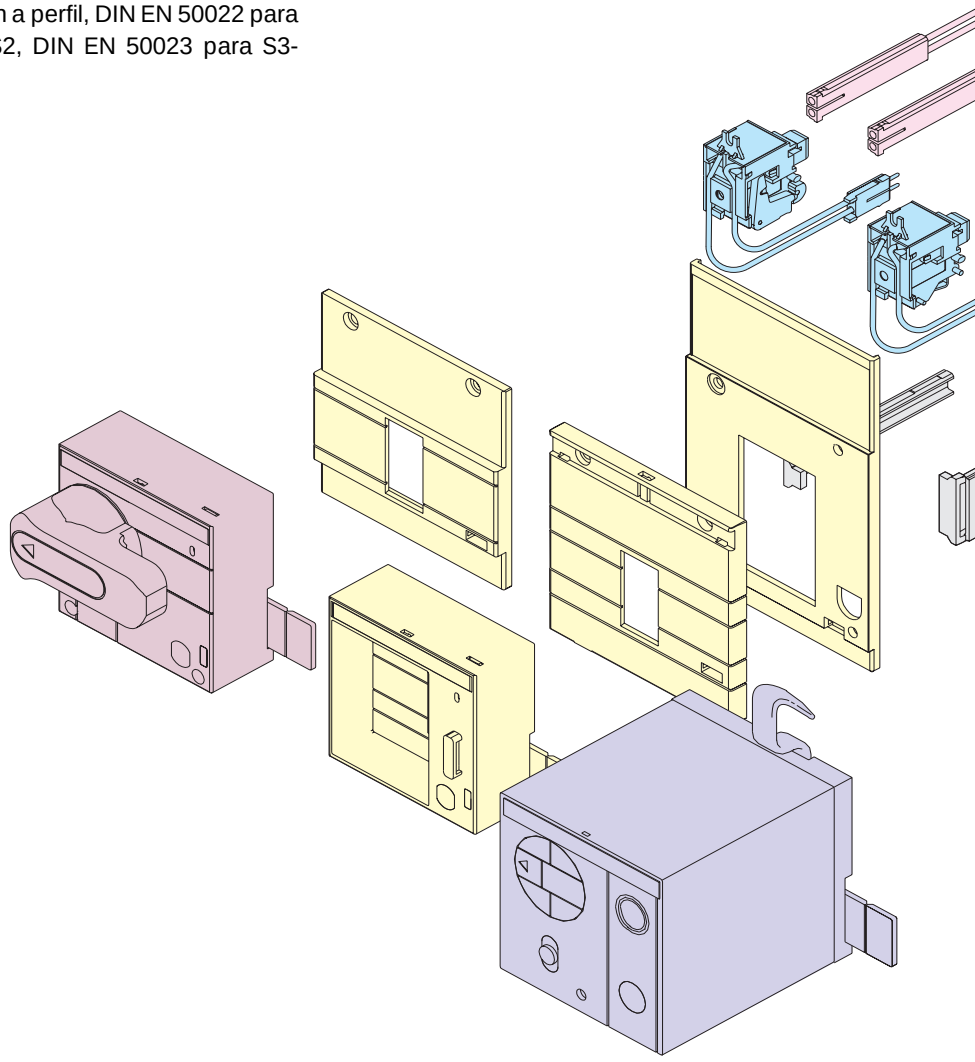
La inserción/extracción de la parte móvil se efectúa por medio de la correspondiente manivela de maniobra suministrada con el interruptor en la versión parte móvil de interruptor extraíble o con el kit de transformación del interruptor fijo en parte móvil de interruptor extraíble. El mecanismo permite poner el interruptor en posición de seccionado (con los circuitos de potencia y auxiliares desconectados) con la puerta de la celda cerrada, mejorando así la seguridad del operador. La manivela puede insertarse solamente con el interruptor abierto.

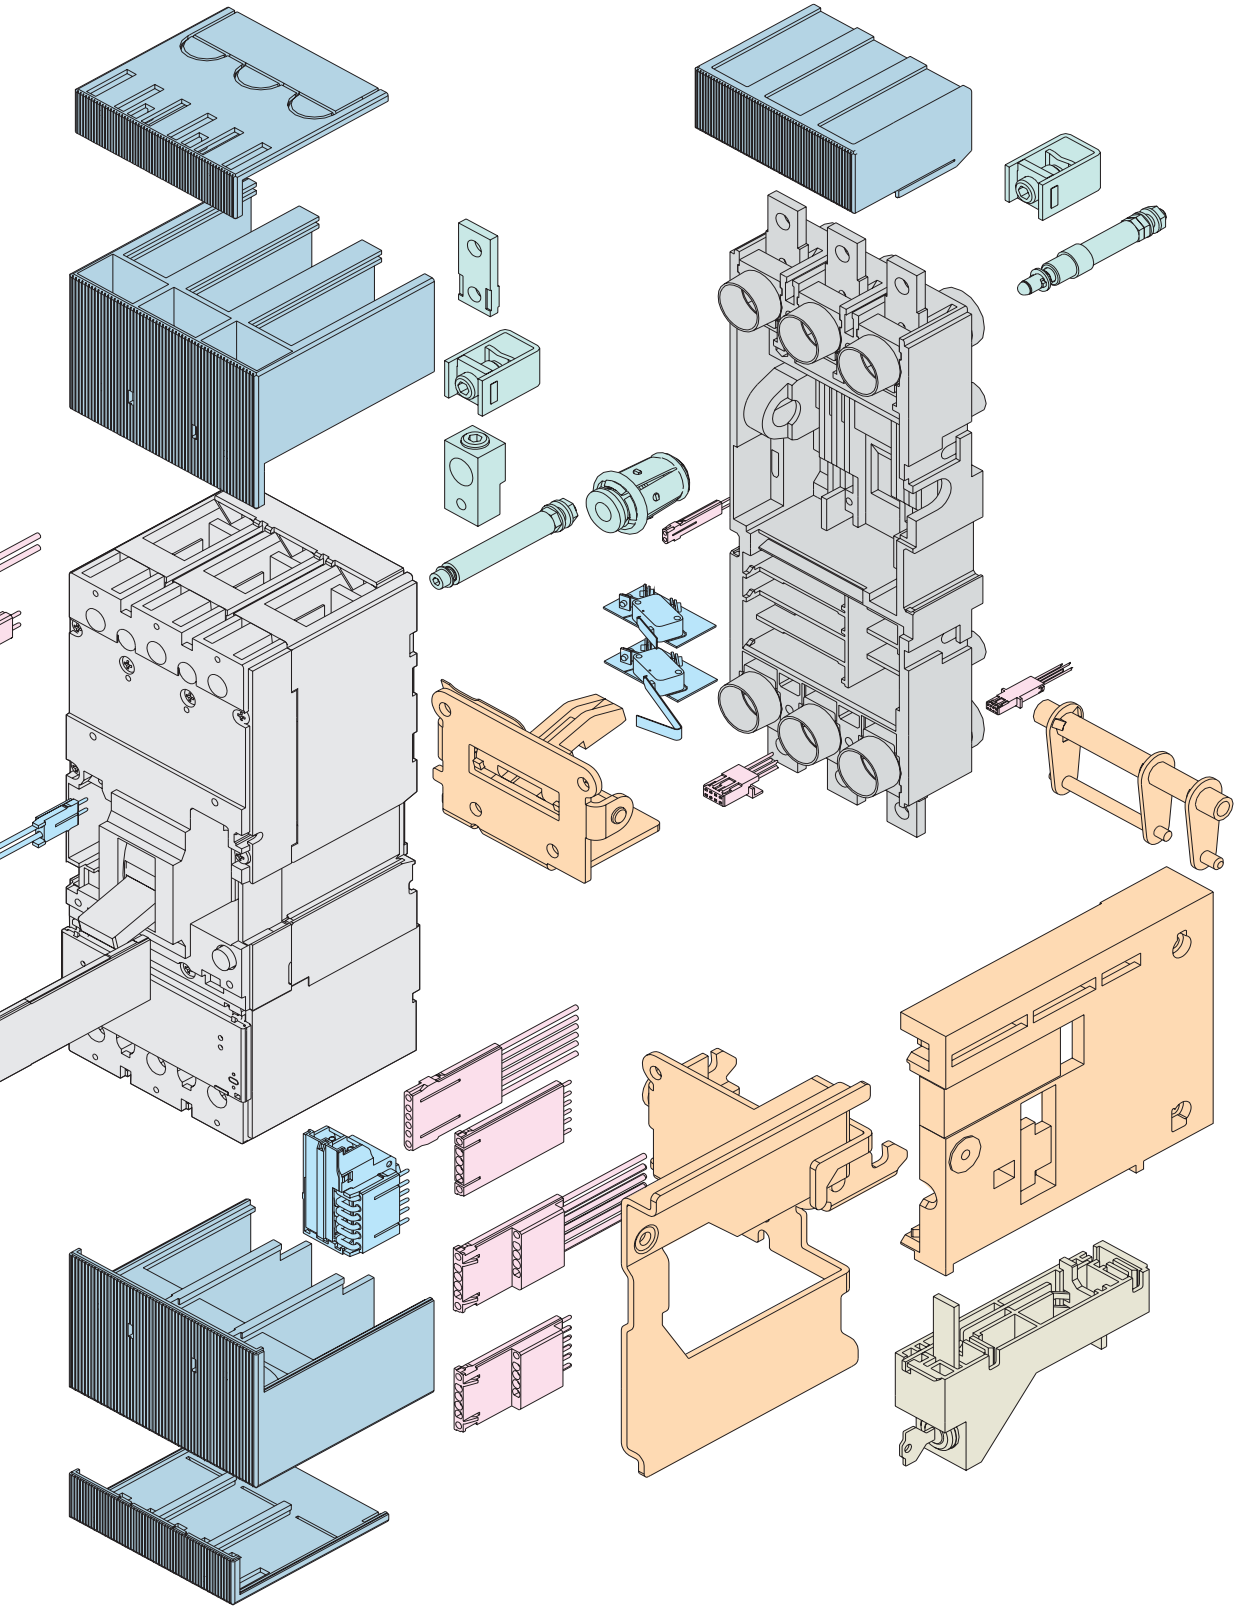
Tras remover o extraer el interruptor, puede maniobrarse en abierto/cerrado y, mediante las correspondientes prolongaciones de conexión, pueden realizarse pruebas en blanco de funcionalidad de los circuitos de mando auxiliar.

Accesorios

Partiendo dal interruptor automático en ejecución fija, mediante el montaje del kit de transformación, se obtienen todas las demás versiones que satisfacen las diversas exigencias de instalación.
Están disponibles:
– El kit para la transformación de interruptor fijo a parte móvil para interruptor enchufable y extraíble
– El kit de transformación para los terminales de conexión que permiten obtener terminales anteriores y posteriores para cable CU/Al, terminales anteriores y posteriores para pletina.

También están disponibles diversos accesorios:
– Relé de apertura
– Relé de mínima tensión
– Contactos auxiliares
– Contactos de posición
– Accesorio para fijación a perfil, DIN EN 50022 para los interruptores S1-S2, DIN EN 50023 para S3-S4-S5
– Mando motor de acción directa y de acumulación de energia
– Mando giratorio directo y reenviado para la puerta del compartimiento
– Relés diferenciales
– Accesorios para relés de sobrecorriente con microprocesador como la unidad de señalización, la unidad de diálogo y la unidad de actuación, y TA externo
– La parte fija para interruptores enchufables o extraíbles con terminales anteriores para cable o pletina y terminales posteriores para pletina.





Relés de sobreintensidad con microprocesador

CSIS9039

Relé SACE PR211/P

CSIS9040

Relè SACE PR212/P

Los interruptores automáticos SACE Isomax S4, S5, S6 y S7 para la protección en corriente alterna pueden equiparse con relés de sobreintensidad de la serie SACE PR211/P y SACE PR212/P realizados con la tecnología electrónica del microprocesador. Esto permite obtener funciones de protección que garantizan una elevada fiabilidad, precisión de las intervenciones e insensibilidad al ambiente exterior. La alimentación necesaria para el correcto funcionamiento está suministrada directamente por los transformadores de corriente del relé, en presencia de una corriente de fase ≥15% de la corriente nominal de los mismos, incluso con una sola fase bajo tensión. La regulación es única para las fases y el neutro y el disparo es simultáneo para todos los polos del interruptor con características de actuación que no notan la influencia del ambiente externo. La funcionalidad del relé puede controlarse mediante el dispositivo de test SACE TT1 portátil, alimentado con pilas normales.

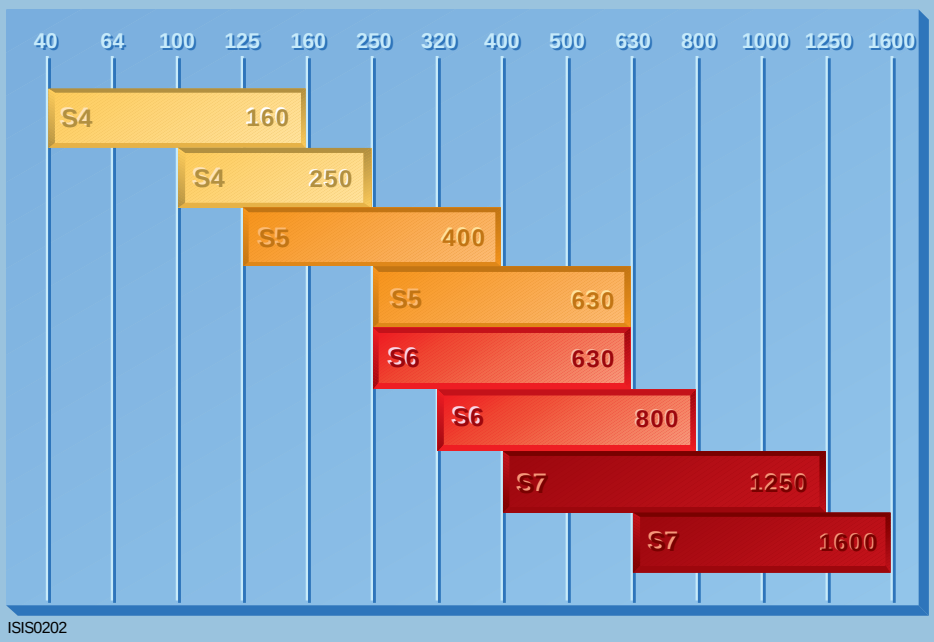
SACE PR211/P

El relé SACE PR211/P realiza funciones de protección contra la sobrecarga L y el cortocircuito instantáneo I, y se encuentra disponible en las versiones con funciones I y LI.
Gracias a la amplitud de las regulaciones, dicho relé está especialmente indicado para todas las aplicaciones de distribución en las cuales se necesitan fiabilidad y precisión en las actuaciones y cuando se necesita exclusivamente la protección magnética (de 1,5 ...12 x In), utilizando el relé SACE PR211/P en la versión I.

SACE PR212/P

El relé SACE PR212/P realiza funciones de protección contra la sobrecarga L, el cortocircuito retardado S e instantáneo I, y contra el defecto a tierra G. Se encuentra disponible en las versiones PR212/P con funciones LSI y LSIG; esta última consiente adoptar las unidades de señalización PR212/K, de diálogo PR212/D y de actuación PR212/T que pueden utilizarse simultáneamente o por separado, salvo la unidad de actuación PR212/T que se suministra siempre con la unidad de diálogo.
Está especialmente indicado en aplicaciones con exigencias de coordinación selectiva, protección de tierra contra los riesgos de incendio y defectos evolutivos, control y parametrización remoto, supervisión de la red y gestión centralizada de las cargas.

En los interruptores tretrapolares, normalmente el neutro está protegido con regulaciones que corresponden al 50% de la regulación de la protección de las fases. Con los interruptores tripolares y neutro distribuido, se pueden utilizar transformadores



Campo de aplicación de los interruptores automáticos con relé de sobreintensidad con microprocesador.

amperimetricos externos que se han de conectar directamente tanto al relé SACE PR211/P como al relé SACE PR212/P según las regulaciones indicadas en la tabla. Si se solicita en el pedido, es posible obtener la protección plena del neutro con una regulación correspondiente al 100% de la regulación de la protección de las fases.

Relés de sobreintensidad termomagnéticos

CSIS9041

Los interruptores automáticos SACE Isomax S1, S2, S3, S5 y S6 pueden equiparse con relés termomagnéticos y se utilizan en la protección de redes en corriente alterna con los interruptores S1, S2 y S3 (para aplicaciones de 10 a 250 A) y en corriente continua con los interruptores S1, S2, S3, S5 y S6 (de 10 a 800 A). Efectúan la protección contra las sobrecargas con dispositivo térmico (con umbral fijo para S1 y regulable para S2, S3, S5 y S6) realizado con la técnica del bimetal y la protección contra el cortocircuito con dispositivo magnético (con umbral fijo para S1, S2 y S3 y regulable para S5 y S6). Los interruptores tetrapolares se suministran siempre con el neutro protegido por el relé.

Los relés solo magnéticos en los interruptores automáticos SACE S1, S2 y S3 poseen un umbral de intervención fijo según lo indicado en la tabla. Para S1, el relé solo magnético está disponible en la versión con poder de corte N=25 kA; para S2 con poder de corte S= 50 kA, no está disponible el relé solo magnético en la versión 5Ith.

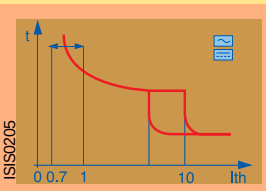
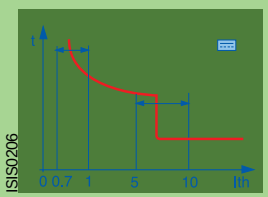
La indicación “R” identifica la corriente de regulación para la protección de las fases (L1-L2-L3) y del neutro (segunda línea). Las combinaciones indicadas son las combinaciones suministradas de serie. Bajopedido, se pueden suministrar interruptores con neutro al 100% de la regulación de las fases

Los relés termomagnéticos en los interruptores automáticos SACE S2 y S3 poseen el elemento térmico con umbral regulable 0,7 ... 1 x In. El valor de corriente regulado que se obtiene actuando en el correspondiente selector tiene que considerarse nominal a 40 °C. El elemento magnético posee un umbral de actuación fijo con valores de intervención que varían en función de la regulación de las fases.



ISIS0205

Los relés termomagnéticos en los interruptores automáticos SACE S5 y S6 poseen el elemento térmico con umbral regulable 0,7 ... 1 x In. El valor de corriente regulado que se obtiene actuando en el correspondiente selector tiene que considerarse nominal a 40 °C. El elemento magnético se puede regular de 5 ... 10 x In. En la tabla se indican los valores máximos de intervención magnética (10 x In) para la protección de las fases (L1-L2-L3) y del neutro.



ISIS0206

Los umbrales de intervención de la protección magnética dependen de la regulación adoptada tanto para la protección de las fases (L1-L2-L3)como del neutro. Los relés denominados 10 Ith están indicados para todas las aplicaciones de distribución mientras que los relés denominados 5 Ith se usan especialmente cuando se necesita un umbral de intervención magnética baja.

Relés diferenciales

CSIS9042

CSIS9043

Relés diferenciales SACE RC211 y RC212

Los relés diferenciales de la serie SACE RC211 y RC212 pueden instalarse tanto en los interruptores automáticos SACE Isomax S1, S2 y S3 como en el interruptor de maniobra-seccionador SACE S3D. Los interruptores automáticos diferenciales combinan en un único aparato la función diferencial con la función de protección contra las sobrecorrientes e intervienen tanto por la fuga de corriente hacia tierra como por la sobrecarga/cortocircuito. Los interruptores diferenciales “puros”, que se obtienen con el interruptor de maniobra-seccionador S3D solamente son sensibles a la corriente de defecto a tierra y se utilizan generalmente como seccionadores principales en pequeños cuadros de distribución hacia servicios finales.

El uso de interruptores diferenciales “puros” y “no puros” permite la monitorización y el control continuo del estado de aislamiento de la instalación con lo que se asegura una protección eficaz contra los riesgos de incendio y de explosión y, en los casos de dispositivos con $I_{\Delta N} \leq 30$ mA, aseguran la protección de las personas contra los contactos directos e indirectos como integración de las medidas obligatorias previstas por las normativas y por las prescripciones de seguridad.

Los relés diferenciales SACE RC211 y RC212 han sido realizados con tecnología electrónica analógica. No requieren alimentación auxiliar ya que se alimentan directamente de la red y el funcionamiento está garantizado incluso con una sola fase en tensión y en presencia de corrientes unidireccionales pulsantes con componentes continuas. Es posible controlar constantemente las condiciones de funcionamiento del relé mediante pulsador de prueba del circuito electrónico e indicador magnético de intervención diferencial.

Los relés diferenciales están realizados en conformidad con las normativas:

– IEC 947-2 apéndice B,
– IEC 255-4 e IEC 1000: para la protección contra los disparos intempestivos;
– IEC 755: para la insensibilidad a las componentes continuas de corriente.

Los relés SACE RC211 y RC212 actúan directamente en el interruptor mediante un solenoide de apertura suministrado con el relé, que se tiene que alojar en el correspondiente hueco realizado en la zona del tercer polo.

Relé diferencial SACE RCQ

CSIS9044

Los interruptores automáticos SACE Isomax S4, S5, S6 y S7 pueden combinarse con los relés diferenciales SACE RCQ con transformador toroidal separado (se tienen que instalar externamente en los conductores de línea) y se pueden utilizar con umbrales hasta 30 A de intervención y retardos hasta 5 s o cuando las condiciones de instalación son especialmente difíciles, como en el caso de interruptores ya instalados, espacio reducido en la celda del interruptor, etc.

El relé de cuadro SACE RCQ, gracias a la amplia gama de regulaciones, es adecuado para aplicaciones en las cuales se desea realizar un sistema de protección diferencial coordinado con varios niveles de distribución, desde el cuadro principal a los servicios finales. Está especialmente indicado cuando se requiere una protección diferencial de baja sensibilidad como, por ejemplo, en cadenas selectivas parciales (amperimétrica) o totales (cronométrica), y en aplicaciones de alta sensibilidad (con sensibilidad fisiológica) para realizar la protección de las personas contra los contactos directos.

Cuando se produce una caída de la tensión de alimentación auxiliar, actúa el mando de apertura tras un tiempo mínimo de 100 ms y tras el tiempo programado más 100 ms.

El relé SACE RCQ es adecuado en presencia de corrientes de tierra exclusivamente alternas (Tipo AC), para corrientes alternas y/o pulsantes con componentes continuas (Tipo A) y para realizar la selectividad diferencial.

El relés SACE RCQ es del tipo de acción indirecta y actúa en el mecanismo de disparo del interruptor automático mediante el relé de apertura del interruptor y que se tiene que solicitar e que se tiene que montar en el correspondiente alojamiento del interruptor automático.

Condiciones de uso

CSIS9107

Temperatura de funcionamiento

Los interruptores automáticos SACE Isomax S pueden utilizarse en condiciones ambientales en las cuales la temperatura de la atmósfera circundante presente unos valores comprendidos entre –25 y +70 °C. Los interruptores automáticos equipados con relés de sobreintensidad termomagnéticos poseen el elemento térmico regulado para una temperatura de referencia de 40 °C. Para temperaturas comprendidas entre 40 y 70 °C a paridad de regulación se produce una disminución del umbral de intervención térmica debido al comportamiento del bimetal del relé ante la temperatura. Para temperaturas inferiores a 40 °C, se tiene que considerar, en cambio, un aumento de los umbrales de intervención térmica (véanse las tablas en el capítulo “Accesorios, relés y curvas características”). Los relés electrónicos con microprocesador no sufren variaciones de las prestaciones cuando varía la temperatura, pero hay que reducir la regulación máxima para la protección contra las sobrecargas (L) para tener en cuenta los fenómenos de inercia que se producen en las partes de cobre del interruptor atravesadas por la corriente de fase (contactos, móviles y fijos, terminales de conexión) que comportan una disminución de la corriente permanente asignada. Para temperaturas superiores a los 70 °C, no se garantiza el mantenimiento de las prestaciones del interruptor automático. Para asegurar la continuidad de funcionamiento de las instalaciones hay que valorar con atención cómo poder mantener la temperatura dentro de los límites aceptables para el funcionamiento de los diferentes dispositivos y no sólo de los interruptores automáticos, es decir, hay que valorar si conviene utilizar, por ejemplo, sistemas de ventilación forzada en los cuadros y en los locales en los que están instalados.

CSIS9108

Altitud

Hasta 2000 metros de altitud, los interruptores automáticos SACE Isomax S no sufren alteraciones en las prestaciones asignadas. Al aumentar la altitud, se modifican las propiedades de la atmósfera en cuanto a la composición, la capacidad dieléctrica, el poder refrigerante y la presión. Por lo tanto, las prestaciones de los interruptores automáticos pasan a un clase inferior, que puede determinarse esencialmente mediante la variación de los parámetros significativos como la tensión asignada máxima de funcionamiento y la corriente asignada permanente.

Altitud		[m]	≤ 2000	3000	4000

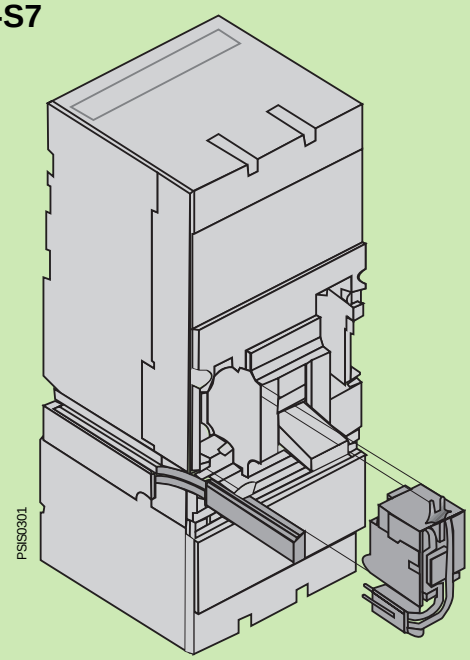
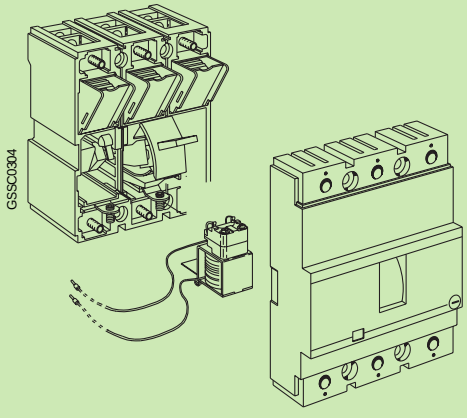
Relés de apertura y mínima

Permiten la apertura del interruptor automático mediante un mando eléctrico (relé de apertura) o mediante la variación de la tensión de alimentación en los bornes del interruptor (relé de mínima tensión). Los relés de apertura y de mínima tensión, alojados y fijados en un hueco de la parte izquierda del interruptor, son siempre en alternativa entre sí.
La alimentación se efectúa mediante los correspondientes conectores que se pueden utilizar indiferentemente para los dos relés. Se exceptúan los interruptores SACE S1 y S2 para los cuales la alimentación se efectúa mediante cables libres de 0,6 m de longitudo con conectores macho - hembra volantes.

SACE S3-S4-S5-S6-S7



SACE S1-S2



Para los interruptores SACE S1 y S2, los relés de apertura y de mínima se fijan a la tapa del interruptor.

Relé de apertura

Permite abrir el interruptor automático mediante un mando eléctrico. El funcionamiento del relé está garantizado para una tensión comprendida entre el -30% y el +10% del valor de la tensión asignada de alimentación Un, en corriente continua y corriente alterna. Se suministra siempre con contacto auxiliar de final de carrera. En la tabla se indican los valores de potencia absorbida en el arranque

Ps	**S1 ... S5**	~	100	[VA]
		-	120	[W]
	S6 - S7	~	150	[VA]

A cada fila y a cada grupo de interruptores (S1, S2, S3, S4, S5, S6 y S7) les corresponde un relé y un código de pedido.

CSIS9046

Conectores para relés

Permiten conectar el relé de apertura o el de mínima tensión al circuito de alimentación. Se encuentran disponibles en las versiones:
– conector macho - hembra para interruptores S1 y S2
– para interruptores fijos S3 .. S7
– para interruptores enchufables/extraíbles S3..S7
El montaje se efectúa a presión en los correspondientes alojamientos situados en el lado izquierdo del interruptor. Normalmente se suministran con cables de 1 m de longitud. Para los interruptores SACE S3, S4 y S5 en ejecución fija se encuentran disponibles bajo demanda con cables de 2 m de longitud.

Prolongación de control

Disponible para interruptores automáticos SACE S3, S4, S5, S6 y S7, permite alimentar los relés con el interruptor en posición de extraído. De esta manera, con el interruptor en condiciones de seguridad, es decir, seccionado con respecto a los circuitos de potencia, es posible efectuar pruebas en blanco sobre la funcionalidad del interruptor.

CSIS9047

Relé de mínima tensión

Abre el interruptor automático por falta de tensión de alimentación del relé o debido a disminuciones hasta valores por debajo de 0,7 x Un con un campo de intervención de 0,7 a 0,35 x Un. Tras la intervención es posible volver a cerrar el interruptor automático a partir de una tensión superior a 0,85 x Un. El montaje del relé se efectúa a presión en la correspondiente sede situada en la parte izquierda del interruptor. Para los interruptores SACE S1 y S2 se sujeta a la tapa.

En la tabla se indican los valores de potencia absorbida durante el servicio,

Pc	**S1 ... S5**	~	6	[VA]
		-	3	[W]
	S6 - S7	~	10	[VA]
		-	4	[W]

y los valores de la tensión de alimentación Un [V] para grupos de interruptores.

A cada fila y a cada grupo de interruptores (S1, S2, S3, S4, S5, S6 y S7) les corresponde un relé y un código de pedido.

CSIS9048

Relé de mínima tensión retardado

El relé de mínima tensión se puede suministrar con un retardador electrónico exterior para retardar la apertura del interruptor en caso de disminución o de falta de tensión de alimentación, según unos retardos fijos de 0,5 - 1- 2 - 3 [s] y evitar, así, intervenciones intempestivas causadas por defectos temporales en la tensión de alimentación del relé. Se encuentra disponible para los interruptores S3, S4, S5, S6 y S7 con tensiones de alimentación de 110 - 220 V (50 - 60 Hz); el relé de mínima tensión suministrado se encuentra alimentado por el retardador con una tensión de 310 Vcc.

Señalizaciones eléctricas

Permiten llevar al exterior del interruptor automático informaciones sobre el estado de funcionamiento del mismo.
La instalación de estos accesorios se efectúa directamente por la parte frontal del interruptor, en los correspondientes huecos, situados en la parte derecha del interruptor, totalmente segregados de las partes bajo tensión, proporcionando más seguridad al usuario.

CSIS9121

Contactos auxiliares

Realizan la señalización eléctrica del estado de funcionamiento del interruptor automático:
– Abierto/Cerrado: indica la posición de los contactos del interruptor.
– Intervención de relés: señala la apertura del interruptor debido a una intervención del relé de sobrecorriente (debido a sobrecarga, cortocircuito), diferencial, de apertura o de mínima tensión, pulsador de apertura de emergencia del mando del motor o debido a la activación del pulsador de prueba. La señalización se pone a cero al rearmar el interruptor (restablecimiento).

Para los interruptores SACE S3, S4, S5, S6 y S7, los contactos auxiliares del interruptor también se encuentran disponibles en versión dorada para señales digitales, adecuados al uso incluso para tensiones Un < 24 V, con el mismo tipo de señalizaciones y ejecuciones que los de versión estándar.
En alternativa se encuentran disponibles:
– Dos contacto de señalización (conmutados) abierto/cerrado.
– Un contacto de señalización (conmutado) abierto/cerrado más contacto de señalización (conmutado) de la intervención de relés.
– Un contacto de señalización abierto, un contacto de señalización cerrado y un contacto de señalización (normalmente abierto) de intervención de relés (sólo para S6 y S7).

CSIS9050

Conectores para contactos auxiliares

Permiten conectar los contactos auxiliares al correspondiente circuito de alimentación. Para los interruptores SACE S1 y S2, la alimentación se efectúa mediante cables libres o con conectores macho-hembra volantes. Para los interruptores SACE S3, S4, S5, S6 y S7 los contactos auxiliares (dotados con conectores macho) sólo se pueden alimentar mediante los correspondientes conectores hembra que se deben solicitar indicando el modelo y la versión del interruptor (fijo o enchufable/extraíble). El montaje se efectúa a presión en los alojamientos correspondientes situados en el lado derecho del interruptor.

CSIS9051

Prolongación de control para los contactos auxiliares

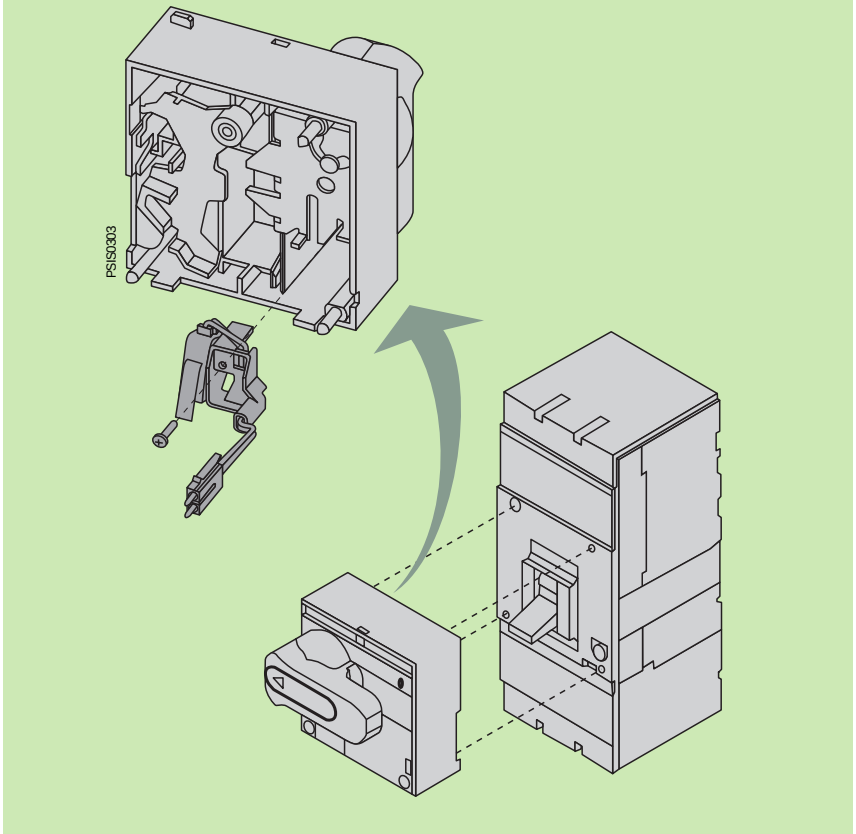
Disponible para los interruptores automáticos SACE S3, S4, S5, S6 y S7, permite conectar los contactos auxiliares al correspondiente circuito de alimentación con el interruptor en posición extraído. Con el interruptor en posición de seguridad, es decir, seccionado con respecto a los circuitos de potencia, es posible efectuar pruebas en blanco sobre la funcionalidad del interruptor.

CSIS9118

Contacto auxiliar anticipado para relés de mínima tensión

El contacto auxiliar anticipado para relé de mínima tensión, accionado por el mando giratorio, mantiene desexcitado el relé de mínima tensión con el interruptor abierto. Sólo se puede aplicar en los interruptores automáticos fijos SACE S3, S4 y S5 con mando giratorio montado directamente en el interruptor. Se suministra con conector hembra del tipo de doble patín para la conexión simultánea del relé de mínima tensión y del contacto de consenso.

SACE S3-S4-S5



PSIS0303

Mando a motor

Permite el mando de apertura y cierre del interruptor automático a distancia y está particularmente indicado para el uso en sistemas de supervisión y control de la red eléctrica. Está dotado con palanca de maniobra manual y pulsador de apertura de emergencia. Un selector permite pasar del funcionamiento automático al funcionamiento manual. Se encuentra siempre preparado para el bloqueo por candados (hasta tres candados con vástago de Ø 6 mm - no suministrados) y, si se solicita, se puede dotar con un bloqueo a llave en posición de abierto, con diferentes llaves para cada interruptor o llaves iguales para grupos de interruptores. La aplicación del mando a motor (en la parte frontal del interruptor) es en alternativa al frontal para el mando por palanca, al mando giratorio y al frontal H = 45 mm (siempre en dotación con el interruptor básico). El montaje del mando a motor no altera las propiedades ni la funcionalidad del interruptor automático. En particular no cambian las versiones disponibles (fija, enchufable/extraíble), los tipos de terminales ni los accesorios aplicables y, para los interruptores SACE S3, S4 y S5, los orificios de las puertas.
Para el uso del interruptor automático en sistemas de automatización en combinación con la unidad de actuación SACE PR212/T se utilizan las versiones con tensión de alimentación a 110Vca/Vcc y 220 V ca.

CSIS9052

Mando a motor de acción directa para interruptores SACE S3, S4 y S5

Los mandos de apertura y cierre se efectúan mediante el motor que actúa directamente en la palanca del interruptor. En la tabla se indican los valores de la tensión de alimentación Un (V).

CSIS9054

Conectores para mandos a motor

Los mandos a motor sólo se pueden alimentar mediante conectores específicos. Son del tipo de doble patín y permiten conectar simultáneamente el mando a motor y los contactos auxiliares con el correspondiente circuito de alimentación. Son en alternativa a los correspondientes conectores sólo para los contactos auxiliares ya que se instalan en el mismo alojamiento. Se tienen que solicitar especificando el modelo y la versión del interruptor (fija o enchufable/extraíble).

Prolongación de control para los mandos a motor

Disponible para los interruptores automáticos SACE S3, S4, S5, S6 y S7, permite conectar tanto los mandos a motor como los contactos auxiliares al correspondiente circuito de alimentación con el interruptor automático en posición de extraído. Con el interruptor en posición de seguridad, es decir, seccionado con respecto a los circuitos de potencia, es posible efectuar pruebas en blanco sobre la funcionalidad del interruptor.
Se tiene que solicitar especificando el modelo y la versión del interruptor (fija o enchufable/extraíble) y excluye automáticamente la correspondiente prolongación de control de los contactos auxiliares.

Mandos y bloqueos

CSIS9055

Mando giratorio

El mando giratorio facilita la maniobra del interruptor automático gracias a su empuñadura ergonómica. Se encuentra dotado siempre con bloqueo por candados que impide el cierre del interruptor. El ojal del bloqueo puede recibir hasta 3 candados - Ø vástago 6 mm (no suministrados).
Si se solicita, se puede dotar con un bloqueo de la puerta de la celda y un bloqueo a llave en posición de abierto. Para los interruptores automáticos SACE S3, S4, S5, S6 y S7, la aplicación del mando giratorio es en alternativa al frontal para bloqueos para interruptores con mando por palanca y al mando a motor. Se encuentran disponibles diferentes tipos de mandos giratorios.

	S1-S2	S3-S4-S5		S6-S7	
	F / P	F / P	W	F	W

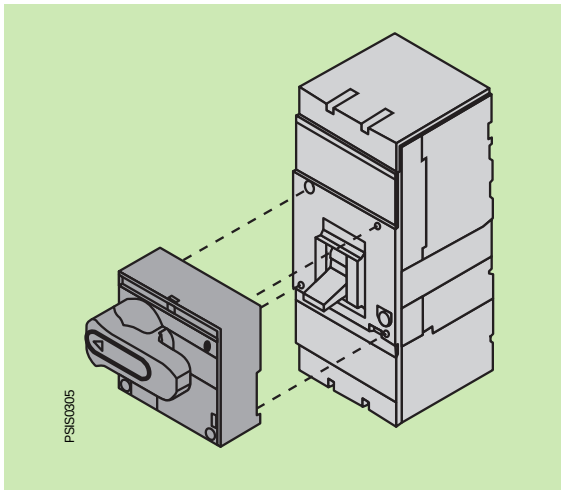
Prolongación para mando reenviado	300 mm	500 mm	-	-	-

Para los interruptores automáticos SACE S1 y S2, el mando giratorio es de tipo reenviado con un eje de prolongación de longitud fija para el montaje en la puerta de la celda. Se puede suministrar un accesorio para regular la distancia hasta una longitud de 300 mm. Para los interruptores automáticos SACE S3, S4 y S5, el mando giratorio de emergencia está dotado de una maneta de color rojo y una placa amarilla y es adecuado para el mando de máquinas herramienta. Para los interruptores SACE S3, S4 y S5, la versión a distancia regulable para el montaje en la puerta de la celda para interruptor fijo o enchufable se suministra con eje de prolongación de 300 mm de longitud. Se puede suministrar un accesorio para regular la distancia hasta una longitud de 500 mm. La posición del mando giratorio indica con exactitud la posición de los contactos: abierto, cerrado, abierto por relés, etc.. La regulación de los relés de sobreintensidad y la tarjeta de caracteristicas del interruptor automático permanecen accesibles al usuario. Para los interruptores fijos SACE S6 y S7 siempre se suministra el marco para la puerta de la celda, mientras que para los interruptores fijos o enchufables SACE S3, S4 y S5 se puede utilizar el marco normal suministrado con el interruptor fijo con mando por palanca.



PSIS0305

CSIS9056

Frontal para mando por palanca

Se puede instalar en los interruptores automáticos SACE S3, S4, S5, S6 y S7 fijos, enchufables o extraíbles. En caso de interruptores extraíbles instalados en celda, permite mantener el grado de protección IP40 durante toda la carrera de seccionamiento del interruptor. Se suministra siempre con bloqueo por candados en posición de abierto (Ø vástago 6 mm hasta tres candados - no suministrados) que impide el cierre del interruptor. Si se solicita, se puede dotar con bloqueo a llave en posición de abierto para uno o más interruptores y con bloqueo de la puerta de la celda. Se encuentra disponible en las versiones:
– para interruptor fijo o enchufable;
– para interruptor extraíble.
Para los interruptores fijos SACE S6 y S7 siempre se suministra el marco para la puerta de la celda, mientras que para los interruptores fijos o enchufables SACE S3, S4 y S5 se puede utilizar el marco normal suministrado con el interruptor fijo con mando por palanca.

CSIS9057

Bloqueo a llave en posición de abierto

Permite bloquear la maniobra mecánica de cierre del interruptor automático. Se encuentran disponibles en la versiones:
– bloqueo con llave diferente para cada interruptor;
– bloqueo con llaves iguales para grupos de interruptores.

Se suministran bloqueos diferentes para mando a motor de acción directa, mando a motor de acumulación de energía, mandos giratorios o frontal para bloqueos para mando por palanca. El bloqueo del interruptor automático en posición de abierto asegura el seccionamiento del circuito en conformidad con la Norma IEC 947-2.

CSIS9060

Bloqueo de la puerta de la celda

Impide la apertura de la puerta de la celda con el interruptor cerrado. Se puede utilizar con los interruptores SACE S3, S4, S5, S6 y S7 en ejecución fija, enchufable o extraíble y equipados con mando giratorio o frontal para bloqueos para mando por palanca. Está formado por dos elementos: uno aplicado al mando giratorio o al frontal para bloqueos y el otro formado por un tope metálico que se debe aplicar en la puerta de la celda.
Para los interruptores automáticos SACE S1-S2 forma parte integrante del mando giratorio.

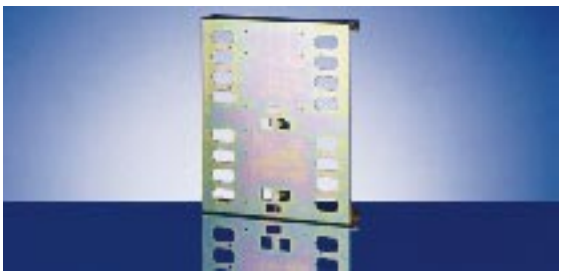
CSIS9058

Bloqueo por candados para palanca de maniobra

Se aplica a la tapa de los interruptores automáticos SACE S1 y S2 para impedir el movimiento de la palanca de maniobra. Si se encuentra activado, el interruptor permanece bloqueado en posición de abierto garantizando el seccionamiento del circuito en conformidad con la Norma IEC 947-2.

Bloqueo antimanipulación

Se aplica a la tapa de los interruptores automáticos SACE S2 y S3 en correspondencia con el botón de regulación del elemento térmico del relé termomagnético e impide la manipulación.



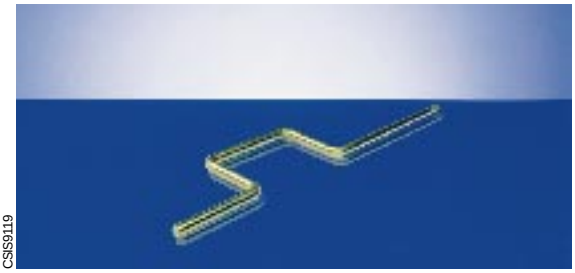
CSIS9061

Enclavamiento mecánico entre dos interruptores

Permite instalar dos interruptores en un único soporte y los convierte mecánicamente interdependientes mediante bielismos. Impide el funcionamiento en paralelo de dos fuentes de alimentación (por ejemplo normal - emergencia). Está formado por un kit de palancas y accesorios de montaje y por un soporte metálico.
Los interruptores y los accesorios de mando se tienen que solicitar aparte. El enclavamiento mecánico se encuentra disponible para interruptores SACE S3, S4, S5, S6 y S7 en dos versiones: para interruptores montados lateralmente y para interruptores sobrepuestos.

Kit de transformación

Los interruptores automáticos SACE Isomax S, a partir de la versión fija con terminales anteriores, se pueden transformar en las diferentes ejecuciones utilizando los Kit de transformación. Esto hace que la gestión del producto, de sus versiones y de los almacenes sea muy flexible. En cualquier caso, siempre es posible solicitar el interruptor en la versión deseada completamente preparada en la fábrica.



CSIS9119

Manivela de extracción

Permite extraer e insertar, incluso con la puerta cerrada, el interruptor extraíble en la parte fija. La manivela es igual para toda la gama de interruptores y se suministra siempre en dotación con el kit de transformación o con los interruptores suministrados en versión extraíble.

CSIS9062

Kit de transformación en parte móvil para interruptor enchufable

Permite transformar el interruptor fijo con terminales anteriores en la parte móvil de un interruptor enchufable. El kit está formado por:
– contactos de seccionamiento en forma de tulipa
– estructura metálica
– tornillos y tuercas de montaje
Para completar el interruptor se necesita la parte fija.

CSIS9063

Kit de transformación en parte móvil para interruptor extraíble

Permite transformar el interruptor fijo con terminales anteriores en la parte móvil de un interruptor extraíble. El kit está formado por contactos de seccionamiento, estructura metálica, tuercas y tornillos de montaje. El interruptor extraíble tiene que estar dotado con uno de los siguientes accesorios:
– frontal para bloqueos para mando por palanca
– mando giratorio directo
– mando a motor
para poder realizar el bloqueo a la extracción/inserción, si es necesario. Para completar el interruptor se necesita la parte fija.

Accesorios para parte fija del interruptor enchufable o extraíble

CSIS9104

CSIS9065

Parte fija

La parte fija permite realizar el interruptor automático en versión enchufable o extraíble. Se puede montar en el cuadro incluso como alimentación de reserva para completar con el interruptor automático cuando sea necesario. Para los interruptores en ejecución enchufable o extraíble existen diversas posiciones del interruptor:
– Enchufable: insertado - removido
– Extraíble: insertado - extraído - removido
La parte fija para interruptores en versión extraíble está dotada con una guía para sostener la parte móvil en las operaciones de seccionamiento o extracción de la parte móvil, para los interruptores SACE S3, S4 y S5.
Para los interruptores automáticos SACE S6 y S7 las guías son dos.

Guía para la parte fija

Guía para preparar la parte fija de interruptores en versión enchufable en la parte fija de interruptor extraíble SACE S3, S4 y S5.

Terminales para parte fija

Preparan la parte fija para recibir conexiones en cable o en barra. La parte fija para interruptor enchufable o extraíble puede dotarse con terminales de conexión según las indicaciones ilustradas en la tabla.

	S1	S2	S3	S3D	S4	S5	S6	S6D	S7	S7D
Anteriores			●	●	●	●	●	●	●	●
Anteriores para cables de Cu	●	●	●	●	●	●				
Posteriores roscados	●	●	●	●	●	●				
Posteriores planos horizontales							●	●	●	●
Posteriores planos verticales							●	●	●	●

En el caso de parte fija para interruptores SACE S3, S4 y S5 con terminales para cables de Cu se suministra en dotación los cubrebornes altos. Para la parte fija, cada código se refiere a un kit para la aplicación completa de los terminales, tanto superiores como inferiores.

Contactos de posición del interruptor

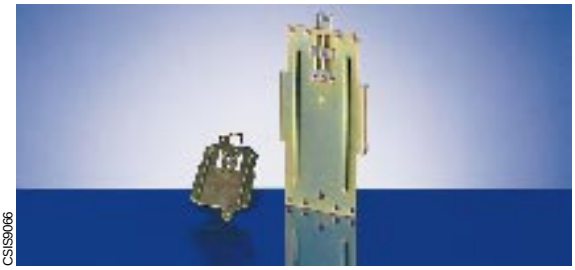
Para la parte fija de los interruptores automáticos SACE S2, S3, S4, S5, S6 y S7 efectúan la señalización eléctrica de posición del interruptor con respecto a la parte fija: insertado, extraído. Sólo se pueden conectar mediante cables libres y se encuentran disponibles en las versiones:
– contactos de señalización interruptor insertado
– contactos de señalización interruptor extraído
En la parte fija es posible instalar un número máximo de tres contactos para S2, dos contactos para S3, tres contactos para S4 y S5, y cinco contactos para S6 y S7, en cualquier combinación.
Los contactos de posición del interruptor también se encuentran disponibles en versión dorada para señales digitales, adecuados al uso incluso para tensiones Un < 24 V, con el mismo tipo de señalizaciones y ejecuciones que los de versión estándar.

SACE Isomax	Tensión asignada Un V~ (50-60 Hz)	V–	Carga óhmica In [A]	Carga óhmica- inductiva In [A]
S2		30	4	
	127		4	2A (cosφ = 0,3)
	220		4	2A (cosφ = 0,3)
S3-S4-S5-S6-S7		125	0,3	
		250	0,15	
	250		6	
	400		3	

Bloqueos para parte fija de interruptor extraíble

Existen una serie de bloqueos a llave o por candados para aplicar a la guía de la parte fija de un interruptor extraíble e impedir la inserción de la parte móvil. Se encuentran disponibles las siguientes versiones:
– Bloqueo por candados, que puede llevar hasta tres candados con Ø vástago de 6 mm (no suministrados).
– Bloqueo a llave en posición de extraido con diferente llave para cada interruptor.
– Bloqueo a llave en posición de extraido entre dos o más interruptores con la misma llave para cada grupo de interruptores.
– Bloqueo a llave tipo Ronis (sin llave).

Accesorios de instalación

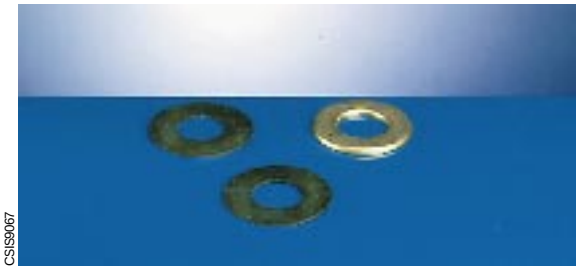


CSIS9066

Accesorio para fijación a perfil DIN

Se aplica al interruptor fijo y permite la instalación en el perfil normalizado DIN. Simplifica el montaje, en cuadros estándar, de los interruptores hasta 630 A.
- Accesorio para fijación a perfil DIN EN 50022 para los interruptores SACE S1 y S2.
- Accesorio para fijación a perfil DIN EN 50023 para los interruptores SACE S3, S4 y S5.

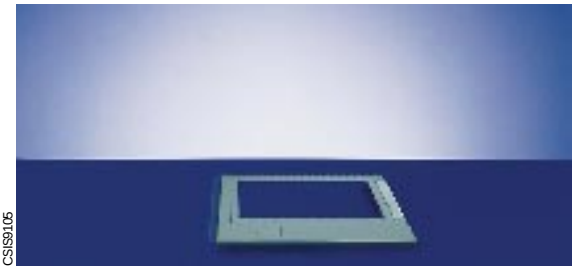
El kit para fijación a perfil DIN para los interruptores SACE S3, S4 y S5 también incluye el frontal H = 45mm.



CSIS9067

IP54 protection for crank handle

For meeting protection class IP54. Available in the following versions:
- for fixed-depth crank handle operating mechanism on compartment door for SACE S1-S2 circuit-breakers
- for adjustable-depth crank handle operating mechanism on compartment door for SACE S3-S4-S5-S6-S7 circuit-breakers.



CSIS9105

Marco para la puerta de la celda

Se suministra siempre con el interruptor automático. Para los interruptores SACE S3, S4 y S5, el marco suministrado con el interruptor fijo se puede utilizar también para el mando giratorio directo, el frontal de bloqueos para mando por palanca y el mando a motor para los interruptores en versiones fijo y enchufable. En caso de que se adopten estos accesorios en los interruptores SACE S6 y S7 en version fijo, se suministra un marco con el accesorio que se debe utilizar en lugar del suministrado con el interruptor fijo.

Para los interruptores extraíbles se suministran marcos específicos que pueden utilizarse también para el mando giratorio directo y el mando motor. Con el mando motor para los interruptores SACE S6-S7 se suministra un marco que se debe utilizar en lugar del suministrado. Para los interruptores SACE S1, S2 y S3 suministrados con diferencial SACE RC211 y RC212 montado lateralmente y preparados para la instalación en el perfil, no se suministra el marco.

CSIS9106

Ejecución extraíble

Los interruptores en ejecución extraíble tienen que estar siempre dotados, en alternativa, con frontal para bloqueos para mando por palanca (dotación estándar), mando giratorio o mando a motor.

Piezas de repuesto

Se encuentran disponibles las siguientes piezas de repuesto:
- palanca de maniobra
- grupo tapa
- cámaras de arco
- contactos de seccionamiento
- solenoide de apertura para relés diferenciales de la serie SACE RC211 y RC212
- kit de arandelas, tornillos y tacos para el montaje de los terminales de conexión

Para más detalles solicitar el catálogo de piezas de repuestos a la División Service de ABB SACE.

Relés diferenciales

CSIS9103

CSIS9102

Relés diferenciales electrónicos SACE RC211 y RC212

Los relés diferenciales electrónicos SACE RC211, RC212 se pueden instalar en los interruptores automáticos tetrapolares SACE S1, S2 y S3 en ejecución fija y se pueden suministrar en dos versiones:
– para el montaje lateral al interruptor
– para el montaje debajo del interruptor
Se encuentran disponible los siguientes relés:
– SACE RC211/1 y RC212/1 para interruptores S1
– SACE RC211/2 y RC212/2 para interruptores S2
– SACE RC211/3 y RC212/3 para interruptores S3
El interruptor automático tetrapolar con relé diferencial se puede dotar con accesorios eléctricos normalmente disponibles para el interruptor:
– relé de apertura
– relé de mínima tensión
– contactos auxiliares
– protección transparente antimanipulación del dispositivo de regulación del relé térmico para los interruptores automáticos SACE S2 y S3.

Los relés de apertura y de mínima tensión se instalan en el correspondiente hueco realizado en el cuarto polo.

Relé diferencial montado lateralmente al interruptor automáticos tetrapolar

Se suministra con:
– cables de potencia para la conexión a los terminales inferiores del interruptor (respetar la correspondencia del neutro y de las fases)
– un solenoide de apertura que se debe instalar en la zona del tercer polo dotado con conector macho - hembra para la conexión al diferencial.
– 2 bridas para la sujeción al perfil DIN (una para el interruptor y la otra para el diferencial)
– conector macho para conectar el pulsador de apertura a distancia (a realizar por el cliente).

Para los interruptores automáticos tetrapolares SACE S1 y S2, el relé diferencial está dotado con terminales anteriores para cables. Para el interruptor automático tetrapolar SACE S3, el relé diferencial está dotado con terminales anteriores y se suministra también un frontal H= 45 mm para el interruptor.
Si se solicita, se pueden montar en los interruptores S3 los terminales anteriores para cables, utilizando el kit estándar del interruptor.

Relé diferencial montado debajo del interruptor automático tetrapolar

Se suministra con:
– un solenoide de apertura que se debe instalar en la zona del tercer polo con conector macho - hembra para la conexión al diferencial.
– conector macho para conectar el pulsador de apertura a distancia (a realizar por el cliente) con el relé diferencial SACE RC212
– marco para la puerta de la celda (uno para SACE S1 y S2; dos para SACE S3)
– protección para el montaje en la zona entre el interruptor automático y el diferencial.

En la versión para interruptores automáticos tetrapolares SACE S1 y S2, el relé diferencial se suministra con terminales anteriores para cables. Si se solicita, se pueden montar los terminales posteriores roscados, utilizando el kit estándar del interruptor. En la versión para interruptores automáticos tetrapolares SACE S3, se suministra también un frontal H = 45 mm para el interruptor. El relé diferencial está dotado con terminales anteriores. Si se solicita, utilizando el kit estándar del interruptor, se pueden montar los:
– terminales anteriores para cables
– terminales anteriores prolongados
– terminales posteriores para cables
o se puede montar los terminales posteriores utilizando el kit de 4 piezas para el interruptor (código 1SDA023365R1) y el kit para el diferencial (código 1SDA025543R1).

Terminales anteriores para cables de cobre o aluminio

Permiten conectar cables de cobre o de aluminio directamente al interruptor.

Para el interruptor SACE S2 estos terminales se tienen que conectar a los terminales anteriores prolongados, que se suministran si el interruptor se solicita equipado directamente en fábrica; mientas que se tiene que especificar el kit de terminales anteriores prolongados, si se solicitan como piezas sueltas.

S6 800	F	3	95 ... 185	19	43
S7 1250	F	4	95 ... 240	21.5	43

El interruptor automático en versión base se suministra con:
- terminales anteriores para los interruptores automáticos SACE S3, S4, S5, S6 y S7;
- terminales anteriores para cables de cobre para los interruptores automáticos SACE S1 y S2.

Se encuentran disponibles diferentes tipos de terminales que se pueden combinar de varias maneras entre sí (superiores de un tipo, inferiores de otro tipo) permitiendo conectar el interruptor automático de la manera más idónea según las exigencias de instalación.

Se puede distinguir entre:
- **terminales anteriores** que permiten conectar cables o barras directamente desde la parte delantera del interruptor.
- **terminales posteriores** que permiten instalar los interruptores en cuadros con acceso posterior a las conexiones en cables y en barras.

Se encuentran disponibles terminales para la conexión de barras o cables con terminales y terminales para la conexión directa de cables. Para cada tipo de terminal se resumen las informaciones necesarias para efectuar la conexión. Para las conexiones con barras se aconsejan pletinas de dimensiones y formas diferentes. Además, se indica el grosor mínimo que debe poseer la pletina que se tiene que conectar, si es de composición diferente al aconsejado. Para la conexión directa con cables sin terminal se indican las secciones mínima y máxima de los cables que se pueden apretar en los bornes y el diámetro del borne. Se indican los valores del par de apriete que se tiene que aplicar a los tornillos de los terminales para cables y a los tornillos utilizados para conectar las barras a los terminales en pletina.

Los interruptores automáticos se pueden solicitar con los terminales deseados, directamente montados en la fábrica, o se pueden solicitar los terminales por separado en kits de 3, 4, 6 y 8 piezas. Existen unos códigos para solicitar directamente interruptores en la configuración con terminales superiores / inferiores del mismo tipo.

Cubrebornes aislantes

Los cubrebornes se aplican en los terminales del interruptor automático para evitar contactos accidentales con partes bajo tensión y garantizar, de esta manera, la protección contra contactos indirectos. Se encuentran disponibles:
- **cubrebornes bajos**, garantizan un grado de protección IP40 para interruptores fijos con terminales posteriores y para partes móviles de interruptores enchufables o extraíbles.
- **cubrebornes altos**, garantizan un grado de protección IP40 para interruptores fijos con terminales anteriores, anteriores para cables y posteriores.
- **cubrebornes para partes fijas** de interruptores enchufables o extraíbles, garantizan un grado de protección IP40 en el frente con la parte móvil insertada. Se encuentran disponible en una sola versión.

Los grados de protección indicados valen para el interruptor instalado en el cuadro.
En los interruptores fijos con terminales:
– anteriores
– anteriores prolongados
– anteriores para cables de cobre
se pueden montar los cubrebornes bajos y los cubrebornes altos, mientras que en los interruptores fijos:
– con terminales anteriores para cables de cobre o aluminio, sólo se pueden montar cubrebornes altos;
– con terminales posteriores planos verticales o horizontales, sólo se pueden montar cubrebornes bajos;
– con terminales posteriores roscados, siempre se suministran los cubrebornes bajos;
– con terminales posteriores para cables de cobre o aluminio, siempre se suministran cubrebornes altos.

Siempre se suministran los cubrebornes altos para los interruptores:
– SACE S2 160 con terminales anteriores para cables de cobre o aluminio.
– SACE S5 400 con terminales anteriores para cables de cobre o aluminio del tipo 2x120 mm².
– SACE S6 800 con terminales anteriores para cables de cobre o aluminio.

Para los interruptores SACE S7 sólo se encuentran disponibles cubrebornes bajos.
Para partes fijas de interruptores enchufables o extraíbles:
– con terminales anteriores prolongados, los cubrebornes se encuentran disponibles sobre demanda;
– con terminales anteriores para cables de cobre, los cubrebornes siempre se suministran;
– con terminales posteriores o en pletina, los cubrebornes no se pueden montar.

Para las partes móviles de los interruptores enchufables o extraíbles y en el kit de transformación de la ejecución del interruptor de fijo a parte móvil siempre se prevén cubrebornes bajos. Los cubrebornes bajos para los interruptores SACE S3, S4, S5 siempre se suministran con diafragmas separadores que se pueden utilizar para garantizar un mejor aislamiento entre las fases.
Los interruptores automáticos SACE S1-S2 siempre se suministran con diafragmas separadores que se pueden utilizar para garantizar un mejor aislamiento entre las fases de alimentación al interruptor automático.
El aislamiento de los conductores o de las barras en el exterior del interruptor corren a cargo del cliente.

Tornillos para precintar los cubrebornes

Se aplican a los cubrebornes de los interruptores fijos o a las partes móviles de los interruptores enchufables o extraíbles. Impiden la remoción de los cubrebornes, altos o bajos, y se pueden bloquear mediante un hilo y un precinto de plomo.

Terminales posteriores para cables de cobre o aluminio

Permiten conectar cables de cobre o aluminio directamente al interruptor.

Relés de sobreintensidad con microprocesador

Los relés con microprocesador SACE PR211/P y SACE PR212/P pueden instalarse en los interruptores automáticos SACE S4, S5, S6 y S7; están autoalimentados y garantizan el correcto funcionamiento de las funciones de protección, incluso con una sola fase en tensión, en presencia de una corriente mayor o igual al 15% del valor asignado de la fase.
El relé de protección está formado por los transformadores amperimétricos (tres o cuatro en función del número de polos del interruptor automáticos), por la unidad de protección SACE PR211/P o SACE PR212/P y por un solenoide de apertura de desmagnetización SA que actúa directamente en el mecanismo de disparo del mando del interruptor automático. Los transformadores amperimétricos se encuentran en el interior de la caja del relé de sobreintensidad y suministran la energía necesaria para el correcto funcionamiento de la protección y la señal necesaria para detectar la corriente. Se encuentran disponibles con corriente asignada primaria según se indica en la tabla.

	Iu [A]	In [A]

		tolerancia: ±20%			

solenoide de apertura SA, el cual conmuta un contacto para la señalización de intervención del relé de sobrecorriente. El restablecimiento de la señalización es de tipo mecánico y se efectúa mediante el rearme de la palanca de maniobra del interruptor automático.
Es posible efectuar la prueba del solenoide de apertura SA mediante el dispositivo de prueba SACE TT1. El resultado positivo de la prueba coincide con la apertura del interruptor.
En la versión con relé SACE PR212/P - LSIG es posible programar los parámetros de regulación de las funciones de protección directamente desde el frente (dip switch en posición MAN), o programar los parámetros a distancia (dip switch en posición ELT) gracias al uso de la unidad de diálogo SACE PR212/D.
En caso de anomalías al establecer los parámetros a distancia, la protección adopta automáticamente el grupo de parámetros programados manualmente en el frente del interruptor. Las unidades de señalización PR212/K o de diálogo PR212/D alimentan de manera continua el relé de protección PR212/P - LSIG (24 Vcc ± 20%) y esto permite programar a distancia los parámetros de regulación incluso con el interruptor abierto.

Dimensiones (H x L x P)	32 x 93 x 45 mm
Temperatura de funcionamiento	–25 °C ... +70 °C
Humedad relativa	90%
Frecuencia de trabajo	45 ... 66 Hz
Compatibilidad electromagnética (LF y HF)	IEC 947-2 Anexo F
Descargas electrostáticas	IEC 1000-4-2
Campo electromagnético irradiado	IEC 1000-4-3
Transitorios de breve duración	IEC 1000-4-4
MTBF previsto	15 años (45 °C)
Características del contacto de señalización	
Máxima corriente permanente asignada	0,5 A
Máxima tensión permanente asignada	24 Vcc/ca
Poder de corte asignado	3 W/VA
Aislamiento contacto/contacto	500 Vc.a.
Aislamiento contacto/bobina	1000 Vc.a.

CSIS9071

Unidad de señalización SACE PR212/K

La unidad de señalización SACE PR212/K puede convertir las señales digitales suministradas por la unidad de protección SACE PR212/P - LSIG en señales eléctricas mediante contactos eléctricos normalmente abiertos. Para el funcionamiento de la unidad se requiere una alimentación auxiliar con una tensión estabilizada a 24 Vcc (±20%, con ondulación máxima - ripple ±5%) e aislada de tierra y funciona independientemente de la presencia de la unidad de diálogo SACE PR212/D. Está conectada al bus interior de la unidad de protección mediante una línea de transmisión serie dedicada a la cual el usuario no puede acceder y por la que transitan todas las informaciones sobre el estado de activación de las funciones de protección en función de las cuales se cierran los correspondientes contactos de potencia para señalar:

– prealarma de la función de protección L (I>0,9 x I1)
– intervención de las funciones de protección L, S, I, G
– intervención del relé
– error de comunicación con la unidad de protección.

La señalización de prealarma permanece activa en toda la duración de la sobrecarga hasta que interviene el relé. Las señalizaciones de intervención de las protecciones se activan durante las fases de temporización y permanecen activadas incluso tras la intervención del relé. Si la señalización de anomalías en el bus interno es activa, la unidad PR212/K deshabilita automáticamente todas las señalizaciones precedentes. Un pulsador de RESET permite poner a cero todas las señalizaciones.

Características del relé de señalización

Alimentación auxiliar	24 V c.c. ±20% ondulación máxima 5%
Máxima corriente permanente asignada	5 A
Máxima tensión permanente asignada	250 V c.a. / 130 V c.c.
Poder de interrupción - carga resistiva	50 W / 800 VA (48 V c.c. e 220 V c.a.)
Poder de interrupción - carga inductiva	25 W / 500 VA (48 V c.c. e 220 V c.a.)
Aislamiento contacto/contacto	1000 Veff
Aislamiento contacto/bobina	2000 Veff

Unidad de diálogo SACE PR212/D

La unidad de diálogo SACE PR212/D permite la comunicación del interruptor automático hacia el exterior y viceversa, mediante una línea de transmisión serie EIA RS485 y según el protocolo de comunicación ABB INSUM (velocidad de transmisión 150 ... 19.200 baud). Se puede adoptar en presencia de la unidad de protección SACE PR212/P - LSIG y se efectúa con módulos exteriores adecuados para la instalación en perfil DIN para interruptores automáticos SACE S4 y S5 o se instala directamente en la caja del relé para interruptores automáticos SACE S6 y S7. Tiene que estar alimentada con una tensión estabilizada a 24 Vcc (±20%, con ondulación máxima - ripple ±5%) y aislada de tierra.

La comunicación hacia el exterior se dirige, en general, a una unidad de Front-End insertada en los sistemas de supervisión y control que, recoge y memoriza las informaciones correspondientes al tramo de instalación controlado y las envía a la unidad de gestión centralizada según las lógicas adoptadas.

Se pueden obtener, mediante el bus de campo, las informaciones correspondientes al estado de la unidad de protección y el estado del interruptor automático:

– prealarma (I>0,9 x I1), sobrecarga función L, S, I, G intervención del relé
– programación del selector local/remoto, estado normal o de parametrización, correcta comunicación en el bus interno
– parámetros programados manualmente mediante los dip-switch
– exactitud de los parámetros programados electrónicamente
– estado del interruptor (abierto - cerrado) y posición del interruptor (insertado - removido/extraído)
– corriente de las fases, del neutro y de tierra, protección de neutro (50/100%), última corriente interrumpida
– número de maniobras mecánicas del interruptor
– calibre TA, tipo de interruptor, tag name de 8 caracteres y 4 números de identificación para el uso del usuario.

En caso de error en la comunicación serie debido a una avería de la unidad de diálogo o debido a la falta de alimentación auxiliar, la unidad de protección SACE PR212/P - LSIG actúa en función de los últimos parámetros programados y, de todas formas, según cuanto programado manualmente. La unidad de diálogo SACE PR212/D siempre se suministra en combinación con la unidad de actuación SACE PR212/T que permite efectuar el cierre o la apertura del interruptor a distancia (Control Remoto) mediante dos salidas digitales, que se pueden inhibir gracias al dip switch (LOC/REM) en posición LOC.
En la parte superior de la unidad de diálogo se encuentran los selectores (Dip switch) que permiten programar la unidad.

CSX9137

Unidad de actuación SACE PR212/T

La unidad de actuación SACE PR212/T permite la apertura y el cierre del interruptor automático mediante el mando a motor instalado en el interruptor. Siempre se suministra en combinación con la unidad de diálogo SACE PR212/D. Para el funcionamiento de la unidad se requiere una alimentación auxiliar con una tensión estabilizada a 24 Vcc (±20%, con ondulación máxima - ripple ±5%) y aislada con respecto a tierra.

La unidad de diálogo PR212/D envía los comandos de apertura y cierre digitales, recibidos por el sistema de supervisión y control, a las entradas de la unidad de actuación SACE PR212/T que efectúa el cierre y la apertura del interruptor mediante el relé de potencia. A estos relés se tiene que conectar el mando a motor del interruptor (utilizar la versión con tensión de alimentación a 110 Vca/cc y 220 Vca).

TA para neutro externo

CSIS9073

Se aplica al conductor neutro y permite efectuar la protección contra defectos a tierra con interruptores automáticos tripolares. El interruptor tiene que estar dotado con el relé SACE PR212/P - LSIG. El transformador tiene que estar conectado al relé de sobrecorriente mediante los conectores específicos X3-X4, seleccionados en función de la ejecución del interruptor automático y del tipo de relé de protección adoptado.

Conectores

CSIS9114

Permiten la conexión del relé de sobrecorriente con microprocesador con una unidad o componentes de la instalación externos. De hecho, se utilizan para que se encuentre disponible, en el exterior, la señal de intervención del relé y para conectar el transformador para protección del conductor neutro externo al interruptor automático o a las unidades de actuación, diálogo y señalización, si se encuentran presentes.
- Conectores X3 para interruptor fijo equipado con relés SACE PR211/P, SACE PR212/P - LSI.
- Conector X3 para interruptores enchufables/ extraíbles (para aplicar en la parte fija) equipados con relé SACE PR211/P, SACE PR212/P - LSI.
- Conectores X3 -X4 para interruptor fijo equipado con relé SACE PR212/P - LSIG.
- Conector X3 - X4 para interruptores enchufables/ extraíbles (para aplicar en la parte fija) equipados con relé SACE PR212/P - LSIG.

Unidad de prueba SACE TT1

CSIS9086

Permite controlar la intervención de los relés electrónicos con microprocesador SACE PR211/P y SACE PR212/P y la prueba de intervención del solenoide de apertura SA. El dispositivo se alimenta mediante una batería de 12 V sustituible, está dotado con un conector-palpador de dos polos polarizados alojados en el fondo de la caja que permite la conexión del dispositivo a los casquillos de entrada de TEST situados en el frente de los relés SACE PR211/P y SACE PR212/P.
Las dimensiones reducidas del accesorio lo hacen prácticamente de bolsillo. El dispositivo de trip test se puede utilizar en los interruptores automáticos SACE Isomax S4, S5, S6 y S7.

Protección contra defectos a tierra 108

Interruptores para uso a 400 Hz 112

Usos más comunes

Cómo escoger el modelo y la ejecución: fijo, enchufable, extraíble

Versiones

Usos

hasta 400 A

Fijo con terminales anteriores para cables de cobre

hasta 1600 A

Fijo con terminales posteriores roscados hasta S6 800, posteriores planos para S7

Pequeñas y medias instalaciones

Con pequeña potencia instalada: complejos residenciales (civiles); centros comerciales y bancos (terciario); pequeñas naves industriales, máquinas (pequeña industria).

Cuadros y cajas con profundidad reducida, en general apoyados a la pared con acceso solamente desde la parte frontal tanto para los aparatos como para los cables.
Es la ejecución más utilizada para las aplicaciones y los cuadros eléctricos de la distribución secundaria y de los circuitos de los servicios finales con corrientes asignadas hasta 400 A; subcuadros, cuadros de distribución con interruptores montados en guías DIN y ranuras de instalación de 45mm, panel de bordo, cuadro de superficie y cuadros para el mando de motores (MCC), normalmente combinados con el cuadro de distribución.

Medias instalaciones

Con media potencia instalada o servicios finales de instalaciones más grandes en las cuales se toleran interrupciones de servicio en caso de defecto.

Cuadros con acceso desde la parte anterior para los aparatos y desde la parte posterior para los cables (pasillo posterior de anchura ≥ 600 mm).
Es la ejecución más utilizada para los cuadros eléctricos Power Center y para los cuadros de subdistribución.

Grandes instalaciones

Cuando no se admiten interrupciones en caso de defecto, por ejemplo, en lugares o procesos de trabajo en los que la falta de servicio provoca situaciones de peligro para las personas, grandes daños, peligros de explosión: hospitales, grandes centros comerciales, grandes bancos (terciario), industrias químicas y petroquímicas, instalaciones siderúrgicas, máquinas - máquina única o proceso - (industria mediana).

CSIS9125

hasta 400 A

Enchufable con terminales anteriores para cables o para pletina de cobre

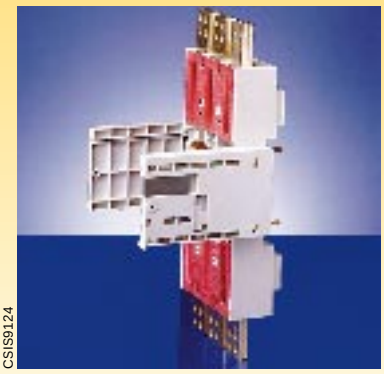
Cuadros y cajas con profundidad reducida, en general apoyados a la pared con acceso solamente desde la parte frontal tanto para los aparatos como para los cables; o donde sea necesario prever instalaciones futuras de más líneas; o donde se han instalado líneas de reserva a otras con un único interruptor enchufable para cada par. Sólo se admiten breves interrupciones de servicio en caso de defectos o mantenimiento.
Disponible hasta S5 400.
Es la ejecución más utilizada para los cuadros eléctricos Power Center y para los cuadros de subdistribución en general con canal lateral para cables.

CSIS9123

hasta 1600 A

Extraíble con terminales posteriores roscados hasta S5 630 o posteriores planos para S6 y S7

Cuadros con acceso desde la parte anterior para los aparatos y desde la parte posterior para los cables (pasillo posterior de anchura ≥ 600 mm); o donde se han previsto instalaciones futuras; o donde se han instalado líneas de reserva a otras con un único interruptor extraíble para cada par. No se admiten interrupciones de servicio y sólo se admiten breves interrupciones en caso de defecto.
Disponible para S3 ... S7 de 160 a 1600A.
Es la solución utilizada para los cuadros eléctricos Power Center y en los cuadros de subdistribución con elevadas potencias en juego, así como en posibles segregaciones hasta el grado máximo (Forma 4).



CSIS9124

hasta 1600 A

Extraíble con terminales anteriores para cables hasta S5 o para pletinas de cobre para S6 y S7

Cuando el espacio de profundidad es limitado y hay que desarrollar el cuadro en longitud.
Cuadros y cajas con profundidad reducida, en general apoyados a la pared con acceso desde la parte frontal para el aparato y para los cables; o donde sea necesario prever instalaciones futuras de más líneas; o donde se han instalado líneas de reserva a otras con un único interruptor extraíble para cada par. Sólo se admiten breves interrupciones de servicio en caso de defectos o mantenimiento.
Disponible para S3 ... S7 de 160 a 1600A.
Es la solución utilizada para los cuadros eléctricos Power Center y en los cuadros de subdistribución con elevadas potencias en juego, así como en posibles segregaciones hasta el grado máximo (Forma 4).

Sistemas de distribución de la energía eléctrica: cómo escoger el interruptor automático

El número de los polos y el tipo de protección que los interruptores automáticos han de poseer depende del tipo del sistema de distribución utilizado (TT, TN o IT) y del tipo de circuito (trifásico o monofásico). Los sistemas eléctricos se clasifican en función:

de la tensión asignada

Categoría	tensión asignada Un [V]
0	≤ 50 c.a.
	≤ 120 c.c.
I	50 < Un ≤ 1000 c.a.
	120 < Un ≤ 1500 c.c.

del sistema de distribución de los conductores activos

Sistema	número de conductores activos
Monofásico	2 fase - fase
	3 fase - neutro
Trifásico	3 L1- L2 - L3
	4 L1- L2 - L3 -N

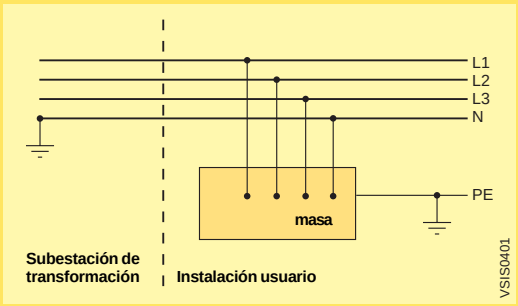
del estado del neutro en relación al cual hay que utilizar un interruptor automático con un número de polos adecuado y prever, eventualmente, la protección y el seccionamiento del conductor de neutro en función del sistema de distribución y del tipo de circuito.

Sistema	Circuitos															
	Trifásico			Bifásico		Fase + N		Trifásico + neutral								
								$S_N \geq S_F$				$S_N < S_F$				
	L1	L2	L3	L1	L2	L1	N	L1	L2	L3	N	L1	L2	L3	N	
TN - C	P	P	P	P	P	P	no	P	P	P	no	P	P	P	no	
TN - S	P	P	P	P	P	P		P	P	P		P	P	P	P	
TT	P	P	P	P	P	P		P	P	P		P	P	P		
IT	P	P	P	P	P	P	P	P	P	P	P	P	P	P	P	

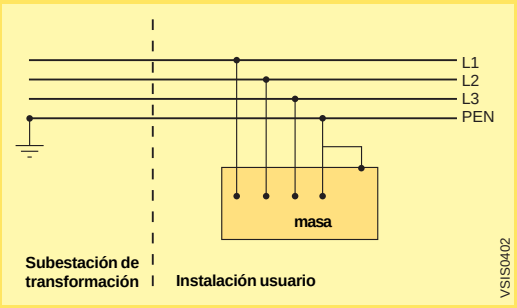
La letra “P” indica cuándo proteger las fases o el neutro y, en consecuencia, el número de polos del interruptor automático
S_N = sección del conductor de neutro
S_F = sección del conductor de fase

El conductor de neutro, cuando está protegido, no tiene que abrirse antes ni tiene que cerrarse después de los conductores de fase, como se garantiza con los interruptores automáticos SACE Isomax S en los cuales la apertura se produce simultáneamente en todos los polos.

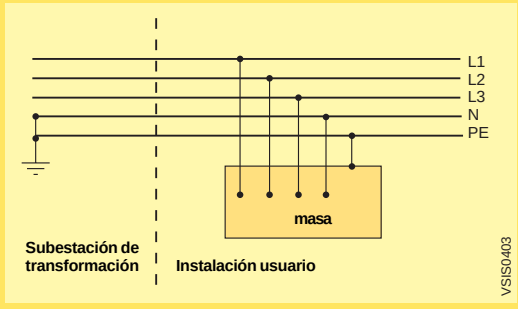
SISTEMA TT



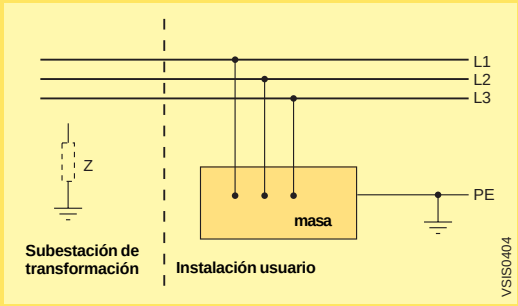
SISTEMA TN-C



SISTEMA TN-S



SISTEMA IT



Sistema con dos instalaciones de tierra separadas:
– una para el neutro de la subestación de transformación
– una para la instalación de distribución.

El conductor de protección PE para la conexión a tierra de las estructuras metálicas (masas) va a parar al sistema de tierra de la instalación de distribución de la compañía y está completamente separado del conductor del neutro N.
La protección contra contactos indirectos está garantizada cuando la tensión hacia tierra UI es menor o igual a 50 V y, en casos particulares, 25 V.
Por lo tanto, debe resultar

$$Rt \leq 50 / I,$$

donde I es la corriente de intervención de la protección de sobreintensidad en el tiempo de 0,4 s o de 5 s o la corriente de intervención del dispositivo diferencial.
Se deduce, por lo tanto, que la protección contra contactos indirectos sólo se puede efectuar con relés de sobreintensidad o relés diferenciales a menos que se obtengan valores bajísimos de la resistencia de tierra Rt.
El sistema TT se adopta para pequeñas y medias instalaciones en las que la compañía eléctrica efectúa el suministro en baja tensión, o en partes periféricas de una instalación de distribución del usuario para las cuales puede tener sentido efectuar redes de tierra separadas.

Sistema con una única instalación de tierra para la subestación de transformación y para la instalación de distribución o para algunas de sus partes.
Un único conductor PEN efectúa la función de neutro N para la alimentación de las cargas que lo requieran y de conductor PE para la conexión a tierra de seguridad de las estructuras metálicas (masas); por lo tanto, el conductor PEN no puede ni debe ser interrumpido ni por interruptores automáticos ni por ningún órgano de seccionamiento durante el funcionamiento normal ya que faltaría la protección de las personas.
La protección contra las tensiones de contacto se efectúa coordinando la corriente de intervención I del dispositivo de protección (sobreintensidad o diferencial) según la fórmula:

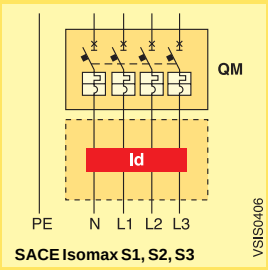
$$I \leq \frac{U_o}{Z_g}$$

donde:
U_o es la tensión asignada a tierra (220 V para sistemas trifásicos a 380 V)
Z_g es la impedancia total del anillo de defecto.
La medición de la resistencia de tierra Rt es necesaria para el control de la coordinación con las protecciones de la parte de la instalación de media tensión antes del transformador, en función de la corriente convencional de tierra I_g y de los tiempos de eliminación del defecto de manera que no se creen tensiones de paso y de contacto superiores a 160 V por periodos de tiempo de ≤ 0,5 s.
El sistema TN-C se utiliza para grandes/medias instalaciones en las que la compañía eléctrica efectúa el suministro en alta tensión o media tensión y el usuario realiza después, una o más subestaciones de transformación efectuando, posteriormente, en el lado de baja tensión, la distribución con 4 conductores (3 fases + N/PE).
Con este sistema de distribución se tienen que utilizar interruptores automáticos tripolares y el conductor PEN se debe seleccionar con una sección suficiente para que quede protegido por los relés de las fases. En caso contrario, hay que prever un relé de sobrecorriente en el conductor PEN que provocará la apertura del interruptor automático sin interrumpir el conductor PEN.

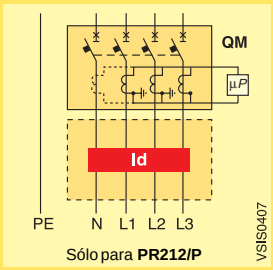
Sistema con una única instalación de tierra para la subestación de transformación y para la instalación de distribución
El conductor PE, para la conexión a tierra de seguridad de las estructuras metálicas (masas), se distribuye completamente separado del conductor del neutro N, si bien se encuentra conectado, en el origen, a la misma instalación de tierra.
También se tiene que considerar como sistema TN-S la parte de la instalación de un sistema mixto TN-CS posterior al punto en el cual se separa el neutro N y el PE y éstos se distribuyen totalmente separados y no conectados entre sí.
El sistema TN-S se utiliza para medias instalaciones en las que la compañía eléctrica efectúa el suministro en media tensión y el usuario realiza después, una o más subestaciones de transformación distribuyendo el neutro totalmente separado del conductor PE e instalando, también, las protecciones diferenciales de tierra.

Sistema en el que ninguna parte activa se encuentra conectada a tierra y, por lo tanto, el neutro del sistema se encuentra aislado de tierra o conectado a ésta mediante una alta impedancia.
La instalación de tierra se efectúa para conectar las masas por motivos de seguridad de las personas. El sistema IT se utiliza en las instalaciones en las cuales es indispensable poseer una continuidad de servicio elevada, como, por ejemplo: hospitales, clínicas, quirófanos, instalaciones con peligro de incendio o explosión como petroquímicas, fábricas de papel, laminados, etc. y, por lo tanto, el primer defecto a tierra no debe provocar una interrupción del servicio.
Se tiene que instalar un dispositivo para el control continuo del aislamiento para señalar el primer defecto a tierra. El segundo defecto es detectado por los relés de sobreintensidad o por los dispositivos diferenciales. Al producirse el primer defecto a tierra hay que eliminar lo antes posible las causas para que no se creen problemas de servicio con un segundo defecto.
Las normas CEI 64-8/3/473.3.2.2 recomiendan no distribuir el neutro ya que en el caso de que se produzca un defecto a tierra en el neutro, se puede perder la continuidad de servicio, que es el motivo que determina la selección del sistema IT.

La polaridad del interruptor



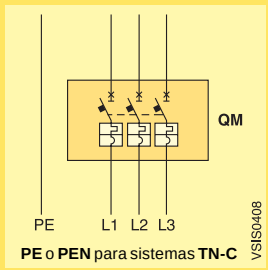
SACE Isomax S1, S2, S3



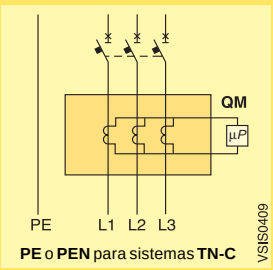
Sólo para **PR212/P**

Interruptores automáticos tetrapolares para circuitos trifásicos en corriente alterna con neutro distribuido (4 hilos + PE)

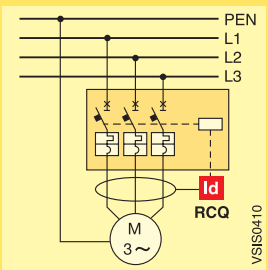
- Se emplean en sistemas de distribución de tipo TT, TN-S e IT para circuitos con neutro distribuido. No se utilizan en sistemas de tipo TN-C.
- El relé termomagnético en el neutro puede omitirse si el circuito está equilibrado y si la protección del conductor de neutro está asegurada por la protección de los conductores de fase. Si se ha previsto, la regulación del neutro tiene que garantizar la protección del conductor de neutro. Para conductores de fase con secciones superiores a 25 mm^2, la sección del neutro es, en general, igual a la mitad de la sección de las fases y, por lo tanto, hay que emplear un relé de protección con regulación reducida para el neutro, como se suministra normalmente con los interruptores automáticos tetrapolares SACE Isomax S.
- Para sistemas IT, el interruptor automático tetrapolar solamente se tiene que utilizar cuando no se tiene en cuenta la recomendación de no distribuir el neutro, establecida por las correspondientes Normas.
- El relé diferencial se emplea en los sistemas de distribución de tipo TT e IT. En los sistemas TN, la coordinación para la protección de tierra se puede obtener dentro de ciertos límites con los relés con microprocesador SACE PR212/P - LSIG, con la función “G” de protección contra defecto a tierra.



PE o **PEN** para sistemas **TN-C**

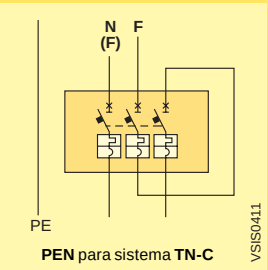


PE o **PEN** para sistemas **TN-C**



Interruptores automáticos tripolares para circuitos trifásicos en corriente alterna sin neutro distribuido (3 hilos + PE)

- Se emplean en sistemas de distribución de tipo TT, TN-S e IT para circuitos con neutro no distribuido y en sistemas de tipo TN-C con o sin neutro. En este último caso, cuando se halla presente el neutro, forma un único cuerpo con el conductor de tierra PE, dando lugar al conductor PEN que no tiene que ser ni interrumpido ni seccionado.
- En los sistemas de tipo TN-S o TT, se utiliza sólo para servicios que no utilizan el neutro, como es el caso de la maniobra y la protección de los motores.
- La protección diferencial no se emplea en los sistemas de distribución TN-C salvo en casos especiales. Para estos últimos, el conductor de puesta a tierra de los servicios a proteger tiene que conectarse al PEN antes de la protección diferencial, como sucede en la protección de un motor contra los defectos a tierra ilustrada en la figura.



PEN para sistema **TN-C**

Interruptores automáticos para circuitos monofásicos en corriente alterna

Para circuitos monofásicos fase-fase o fase-neutro, se pueden utilizar los interruptor automáticos SACE Isomax S tanto tripolares como tetrapolares prestando atención en no interrumpir el conductor PEN en los sistemas de distribución de tipo TN-C.

Instalación en cuadro

Los interruptores automáticos SACE Isomax S pueden adaptarse perfectamente y montarse con facilidad en cualquier tipo de cuadro gracias a los tamaños coordinados en altura, profundidad y anchura. Se pueden montar indistintamente tanto en posición vertical como en posición horizontal a condición de que se respeten siempre las distancias mínimas a las paredes del cuadro. Permiten realizar fácilmente todas las formas de segregación establecidas por las Normas IEC 439-1/CEI EN 60439-1. Para la instalación en cuadro se pueden obtener todos los grados de protección siempre que se instalen los elementos necesarios como, por ejemplo, las juntas en las puertas para los grados IP50/IP54, el cierre o las pantallas en las ranuras de ventilación, el mando en la puerta de la celda para obtener un grado de protección superior al estándar mediante el accesorio que se suministra en dotación con la misma.

Disipación de la potencia

La disipación de la potencia es un dato útil para valorar el perfil de la temperatura que se crea en un cuadro durante su funcionamiento normal. Para ello, para cada unidad del cuadro eléctrico hay que hacer un cálculo de control sobre la disipación térmica teniendo en cuenta:

– las dimensiones generales
– la corriente asignada de las barras y de las conexiones y las correspondientes disipaciones
– las disipaciones de los aparatos montados en el cuadro.

Los valores indicados se refieren a interruptores automáticos tripolares con todos los polos atravesados por corriente. El cálculo para determinar la sobretemperatura puede efectuarse con ayuda del programa DOC de ABB SACE.

Maniobra y protección del lado Baja Tensión de los transformadores trifásicos

Los transformadores se utilizan para cambiar la tensión de alimentación, tanto en suministros de media tensión como en alimentaciones de baja tensión.
En el caso de transformación Media/Baja tensión, la maniobra y la protección de los transformadores introduce problemáticos de coordinación de las protecciones. Efectivamente, cuando se encuentran instalados dos o más transformadores que funcionan en paralelo, el interruptor automático situado en el lado de B.T. del transformador tiene que abrirse cada vez que se abre el interruptor de protección (automático o de maniobra - seccionador con fusibles) del lado de M.T. del transformador, que puede suceder debido a la intervención de los relés de protección, de los fusibles o del relé Buchholz del transformador o debido a una maniobra manual realizada voluntariamente para dejar fuera de servicio el transformador y efectuar, por ejemplo, el mantenimiento.
La apertura del interruptor automático de B.T. mediante un circuito con un relé de apertura impide que el transformador se ponga nuevamente bajo tensión mediante el lado de B.T. con la consecuencia que se alimente el defecto o, todavía peor, se deje bajo tensión una parte de la instalación a la cual se tiene que acceder para efectuar el mantenimiento. Se aconseja realizar dicho circuito de apertura incluso si se prevé instalar en el futuro uno o más transformadores adicionales ya que, inicialmente, dicho circuito puede utilizarse como apertura de emergencia para la línea de alimentación general.
En régimen, las corrientes en vacío pueden alcanzar valores equivalentes al 4-5% de la corriente asignada a plena carga; al elegir los dispositivos de protección hay que considerar los fenómenos transitorios de conexión del transformador durante los cuales la corriente puede presentar valores equivalentes al doble de la corriente asignadaa plena carga.
La maniobra y la protección se puede efectuar con los interruptores automáticos SACE S1, S2, S3, S4, S5, S6 y S7 de 10 a 1600 A como máximo, en corriente alterna. El interruptor automático situado des-

Para elegir los interruptores automáticos SACE Isomax S que se han de instalar tanto en los ramales de los transformadores como en las líneas derivadas después de los mismos, se puede consultar la siguiente tabla correspondiente a los transformadores con tensión en vacío en el secundario igual a 400 V que es la condición de empleo más común. La tabla ha sido realizada considerando una potencia infinita aguas arriba del primario del transformador y se ha supuesto el caso más desfavorable, es decir, que el cortocircuito se produzca en los bornes del transformador.
Por lo que se refiere a los servicios, el cortocircuito se ha considerado después de los bornes del interruptor automático de salida. Los interruptores automáticos de salidas indicados en la tabla garantizan la completa selectividad con los interruptores automáticos de salidade los ramales de los transformadores.

pués de un transformador, además de garantizar el seccionamiento del circuito, protege el transformador contra las sobrecargas y las barras de distribución, situadas después, contra los cortocircuitos. La elección del interruptor automático adecuado para la aplicación se realiza en función:

– de la corriente asignada secundaria del transformador que depende de la potencia aparente en kVA y de la tensión de servicio; el modelo del interruptor automático se elige de manera que se obtenga una corriente asignada superior un 10% como mínimo a la corriente asignada secundaria del transformador
– de la corriente de cortocircuito en el punto de aplicación que depende de la potencia P en kVA y del número de transformadores que funcionan en paralelo así como de la tensión de servicio y de la tensión de cortocircuito U_{cc}% (indicada también con las siglas V_{cc}% o Z_{cc}%) calculada según la siguiente fórmula:

$$I_{cc} = \frac{P \times 100}{1{,}73 \times V \times Ucc}$$

Donde

P = potencia asignada del transformador en kVA

V = tensión asignada secundaria del transformador en V

U_{cc} % = tensión de cortocircuito asignada trifásica del lado de B.T.

Para mayor información sobre el cálculo de la corriente de cortocircuito es posible utilizar el programa DOC para ordenador personal o bien las reglas de cálculo realizadas y distribuidas por ABB SACE. Para los interruptores automáticos que protegen el secundario de los transformadores, el poder de corte tiene que ser mayor que la corriente de cortocircuito debida al número total de los transformadores de igual potencia que están en paralelo menos uno. Obsérvese que, en general, dos transformadores para poder funcionar correctamente en paralelo han de tener el mismo grupo de conexión y la misma tensión de cortocircuito U_{cc}%.

Interruptor salida servicio

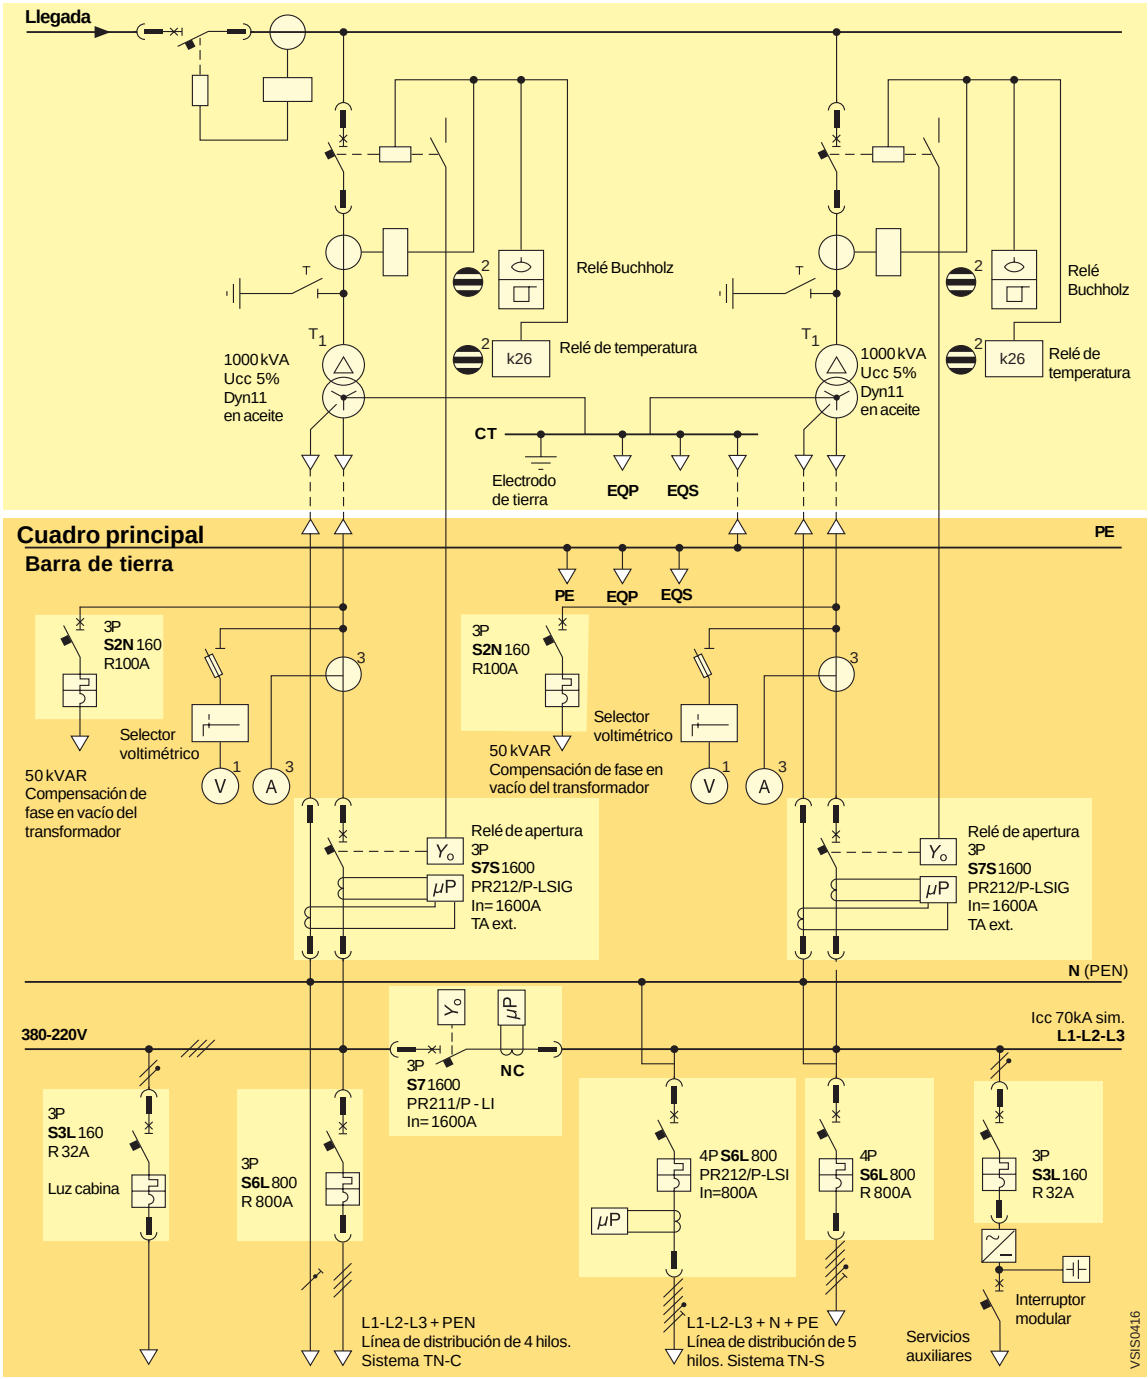
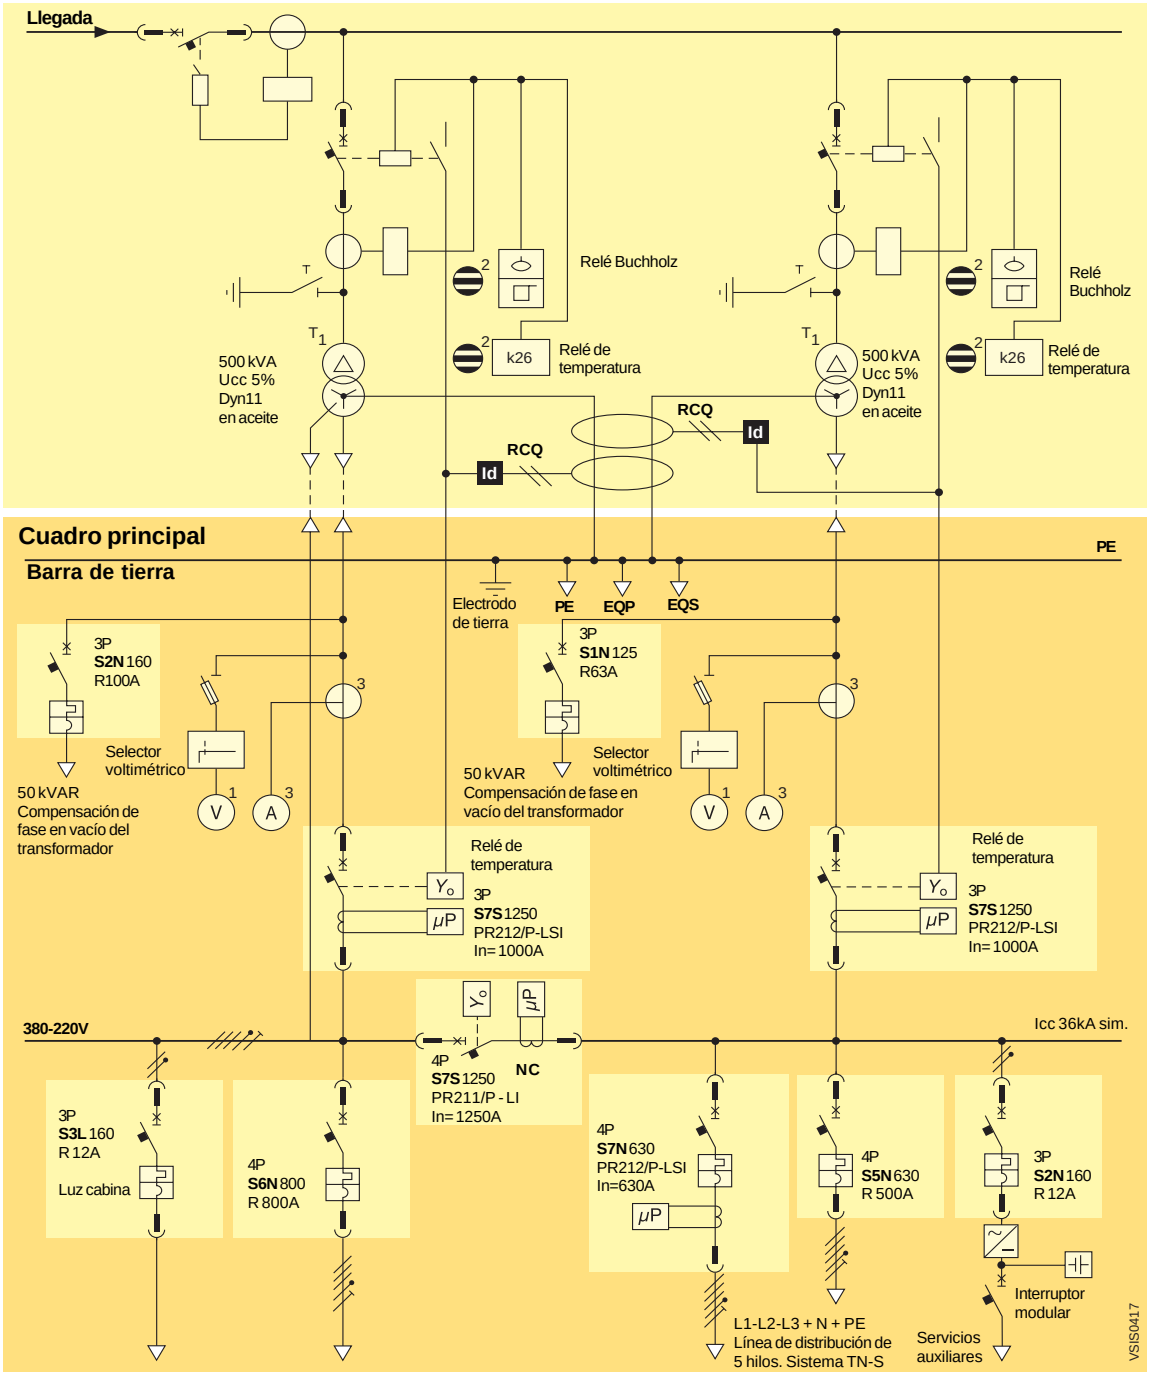
El desarrollo de la red de distribución después del transformador tiene que responder a las exigencias de continuidad de alimentación, flexibilidad en la conducción y, no por último, tiene que realizarse para responder a los precisos requisitos de protección de la instalación de distribución en su totalidad. Las lógicas de conducción llevan a configurar el sistema de distribución según esquemas radiales, de anillo o de doble sistema de barras, mientras que el sistema de protección también ha de tener en cuenta el tipo de sistema de distribución. Los esquemas propuestos se refieren a dos casos típicos de distribución según los sistemas TN-C y TN-S a través de los cuales se evidencia cómo es posible utilizar los interruptores automáticos SACE Isomax en los diferentes niveles de una instalación, elegir

Sistema de distribución TN-C



una versión adecuada (tripolar o tetrapolar) y cómo se pueden determinar las protecciones de sobrecorriente y diferenciales. La coordinación de las protecciones es más necesaria cuanto más elevada es la corriente asignada de los transformadores y, en consecuencia, la posibilidad de provocar problemas de servicio importantes y/o graves daños, o bien cuanto más importante es la continuidad de servicio (por ejemplo, hospitales, centros de cálculo, lugares con presencia de muchas personas, interruptores generales de una instalación). Para el sistema TN-S, el relé diferencial SACE RCQ, insertado entre el centro estrella del transformador y la puesta a tierra del mismo consiente detectar la corriente total a tierra en el caso de que dos transformadores funcionen en paralelo.



Sistema de distribución TN-S

Maniobra y protección de motores trifásicos en c.a.

La maniobra y la protección de los motores eléctricos están realizadas, en general, por un conjunto de dispositivos llamado arrancador protegido. Al elegir estos dispositivos hay que considerar diferentes factores como la potencia del motor, el tipo de motor, el esquema de arranque y las condiciones de defecto que se pueden producir en el tramo de red implicada.

El conductor que alimenta el motor ha de tener una sección mínima suficiente para soportar las corrientes de arranque e, incluso, una capacidad superior a la regulación del relé térmico.

El interruptor automático es el dispositivo que responde completamente a la función de protección contra el cortocircuito y, a veces, a la de maniobra (según el número de maniobras y la frecuencia de las mismas). Los motores de B.T. en corriente alterna pueden protegerse mediante interruptores automáticos SACE Isomax S de S3 a S6 (800 A) para potencias de 0,37 kW hasta un máximo de 355 kW y con las siguientes coordinaciones:

– **Tipo 1** que admite la sustitución o la reparación de los dispositivos del arrancador tras un cortocircuito.
– **Tipo 2** que obliga a que el arrancador pueda reemprender el servicio tras un cortocircuito, se admiten soldaduras en los contactos a condición de que se puedan eliminar con una sencilla operación de mantenimiento.

Por encima de estas potencias, normalmente se utilizan motores alimentados en M.T. (por ejemplo 3 o 6 kV). Para casos especiales con motores de baja tensión con potencias superiores a 355 kW, se emplean interruptores automáticos abiertos de la serie Emax o Megamax. El sistema de protección de los motores tiene que garantizar la salvaguardia ante eventos que pueden provocar sobrecorrientes como, por ejemplo, un funcionamiento anómalo monofásico para motores asincrónicos trifásicos, una excesiva reducción de la tensión de alimentación y la creación de pares resistentes excesivos.

La maniobra y la protección de los motores asincrónicos trifásicos en B.T. se efectúan según unos esquemas en los cuales el interruptor automático realiza diferentes funciones en función de la versión. Los más típicos son los siguientes:

– Arranque directo con un único sentido de marcha. Se emplea en el 90% de los casos.
  El arrancador se compone de diferentes dispositivos según si el interruptor automático realiza funciones de maniobra, protección contra cortocircuito y protección contra sobrecarga.

MANIOBRA

Arrancador protegido formado por:
– interruptor de maniobra-seccionador tripolar
– tres fusibles para la protección contra el cortocircuito
– contactor de maniobra tripolar
– relé térmico combinado con el contactor para la protección de la sobrecarga

Empleo típico:
instalaciones en las cuales se admiten paradas para sustituir los fusibles en caso de defecto.

MANIOBRA - PROTECCIÓN CONTRA CORTOCIRCUITO

Arrancador protegido formado por:
– interruptor automático con mando manual y relé solo magnético
– contactor de maniobra tripolar
– relé térmico combinado con el contactor para la protección de la sobrecarga

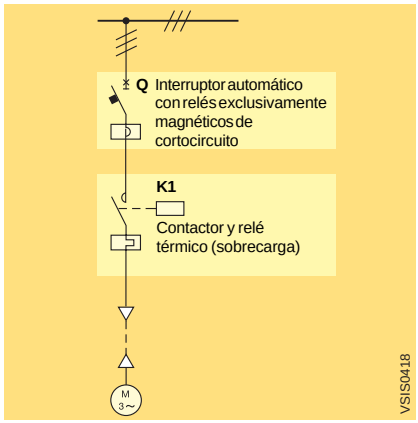
Empleo típico:
instalaciones en las cuales no se admiten paradas para sustituir los fusibles en caso de defecto.

MANIOBRA - PROTECCIÓN CONTRA CORTOCIRCUITO Y SOBRECARGA

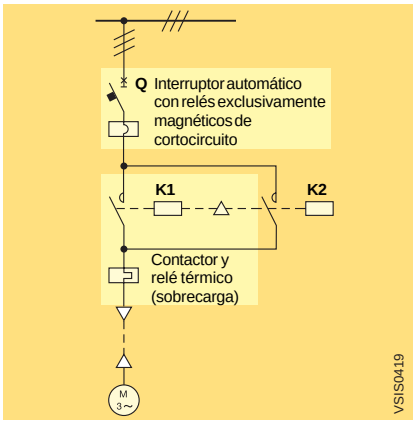
Arrancador protegido formado por:
– interruptor automático tripolar con relé de sobrecorriente y mando manual y/o eléctrico a distancia para el seccionamiento, la protección contra la sobrecarga y el cortocircuito y la maniobra del motor.

Empleo típico:
– grandes motores caracterizados por maniobras muy escasas, por lo que se puede emplear un interruptor
– con mando exclusivamente manual, puede utilizarse en la maniobra y la protección de pequeños motores con corrientes nominales hasta 25-30 A, con muy pocas maniobras y cuando se tolere o sea necesario que el motor no se desconecte de la red de alimentación en caso de falta de tensión como en instalaciones no controladas, sin mandos a distancia ni arranques automáticos tras el fallo de la tensión.

Las funciones del interruptor automático en los esquemas de arranque directo con un único sentido de marcha.



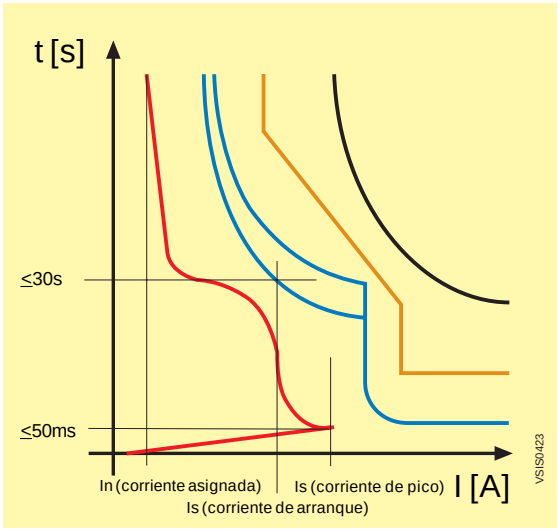
Esquema de arranque directo del motor con un único sentido de marcha



Esquema de arranque directo del motor con inversión de marcha

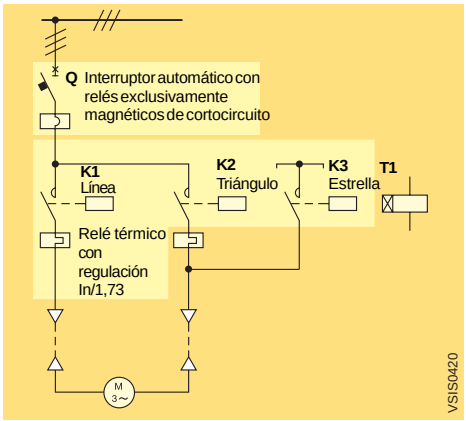
– Arranque directo con inversión de marcha.
– Arranque estrella-triángulo. Se utiliza pare reducir las corrientes absorbidas durante el arranque y no sobrecargar la red de alimentación.
– Arranque con reactancia para disminuir las corrientes absorbidas durante el arranque y no sobrecargar la red de alimentación.
– Arranque con alimentador estático progresivo para disminuir las corrientes absorbidas durante el arranque sin sobrecargar la red de alimentación y con posibilidad de variar la curva de aplicación de la tensión y adaptarla a la máquina acoplada al motor y a las características de la red de alimentación.

Para una correcta elección del interruptor automático hay que determinar:
– la corriente asignada del motor $\mathbf{I_e}$;
– la corriente de cortocircuito en el punto de aplicación; si las cargas de la instalación son mayormente motrices, al valorar el nivel de defecto hay que considerar la contribución de los motores que, en el momento del cortocircuito, se comportan como generadores y, en consecuencia, aumentan el valor de la corriente de defecto con una contribución que se puede valorar aproximadamente en 4 veces la suma de la corriente asignada de todos los motores simultáneamente en servicio en las barras
– la corriente y el tiempo de arranque; las corrientes de arranque para un motor asincrónico varían de 5-7,6 x I_e para un tiempo variable en función de la máquina acoplada (normalmente inferior a 5-6 s);
– la corriente de pico inicial de arranque, al primer instante de conexión, puede variar entre 7,5-15xI_e.

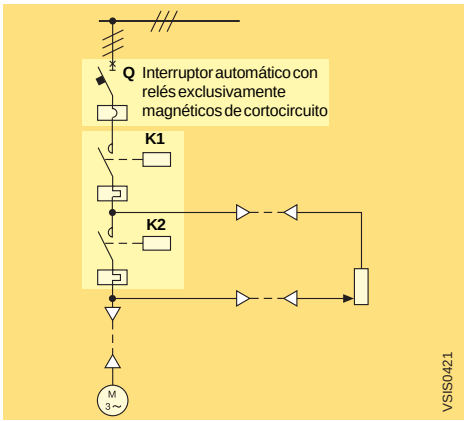


Característica de funcionamiento del motor asíncrono

Para evitar intervenciones intempestivas, el elemento instantáneo de los relés de sobrecorriente de los interruptores automáticos tiene que regularse para una corriente que permita superar la corriente de pico inicial de arranque y la corriente de arranque; además, tiene que coordinarse con el relé térmico en función de su límite de autoprotección. La protección contra cortocircuito es para la línea de alimentación del motor: cuando el cortocircuito se produce en el interior del bobinado del motor no hay nada para proteger en el motor, al máximo se trata de proteger el lugar contra incendios y reducir los daños que puedan afectar a los dispositivos del arrancador.



Esquema de arranque estrella-triángulo del motor



Esquema de arranque con reactancia

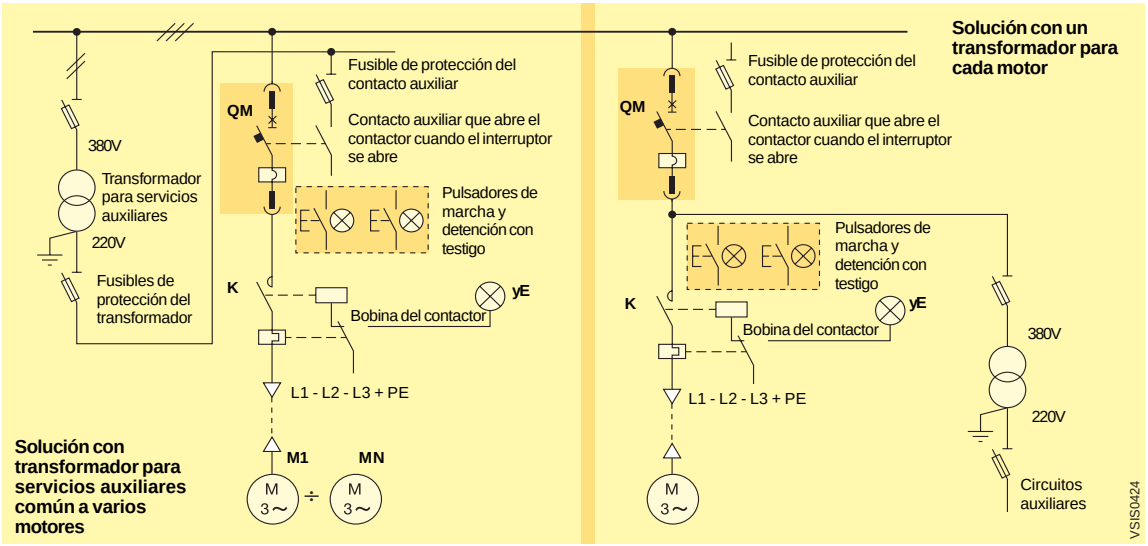
Arrancador formado por interruptor automático, contactor y relé térmico

Las maniobras locales y a distancia se efectúan mediante el contactor de maniobra.
La protección de sobrecarga se efectúa mediante el relé térmico que provoca la apertura del contactor. El relé térmico también asume la función de protección por fallo de fase debida a la interrupción de un conductor o del bobinado del motor y debido al desequilibrio entre las fases como consecuencia de un cortocircuito de algunas espiras del bobinado del motor. En caso de que se produzcan estos defectos, el relé interviene e impide que el motor funcione, se sobrecargue y, por lo tanto, se dañe. La protección por falta de tensión está realizada normalmente por la bobina del contactor, alimentada en general a la tensión del motor (directamente o por medio de un transformador auxiliar) que al desexcitarse abre el contactor. La protección por falta de tensión es fundamental para casi todos los motores debido a los siguientes motivos:

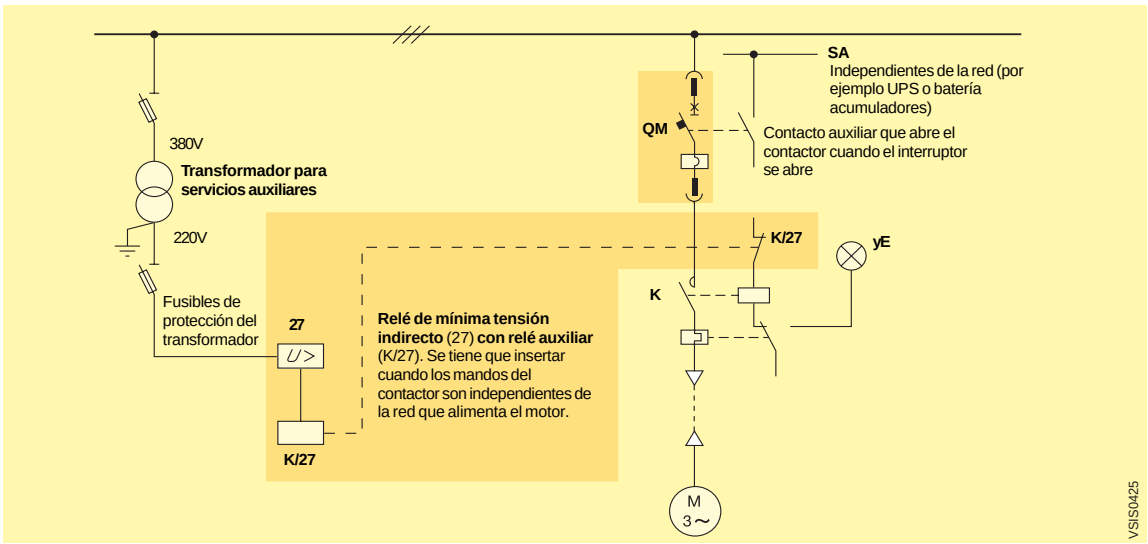
– impedir el arranque simultáneo de todos los motores al restablecerse la tensión ya que podría provocar la intervención de los relés de sobrecorriente de los interruptores automáticos principales y generar problemas de servicio globales;
– impedir el arranque del motor al restablecerse la tensión para garantizar la seguridad de los operadores que acceden a los motores.

Si la bobina no está alimentada por la tensión de red sino por una fuente de alimentación auxiliar con otro origen, por ejemplo, de la batería de acumuladores

Arrancador directo para motor con transformador auxiliar



Arrancador directo para motor con transformador auxiliar y circuito de mando del contactor independientes



de los servicios auxiliares, hay que instalar, en las barras del cuadro, una protección de mínima tensión indirecta que, por medio de relés auxiliares, provoque la apertura de los contactores de los arrancadores.
El interruptor automático se selecciona considerando una corriente asignada de regulación de al menos el 20% de la corriente asignada del motor y un poder de corte igual o superior a la corriente de cortocircuito en el punto de instalación.
Para casos especiales, como por ejemplo, los ventiladores, se pueden necesitar tiempos de arranque muy largos que llegan incluso a 20 s. En dicho caso, hay que aislar (by-pass) el relé térmico con un contactor durante la fase de arranque o bien elegir relés térmicos para arranque pesado que pueden soportar arranques iniciales importantes sin provocar la apertura del contactor.
A continuación, se ilustran dos tablas para facilitar la elección de los interruptores automáticos SACE Isomax S en función de las exigencias de coordinación con los otros dispositivos del arrancador. Las tablas se refieren a motores con una tensión asignada de 400 V.

Maniobra y protección de condensatores trifásicos en c.a.

Compensación de la potencia reactiva

La exigencia de compensar la potencia reactiva se presenta tanto en las redes de transmisión como en las redes de distribución y en las redes industriales. En general, la compensación de la potencia reactiva es necesaria para limitar las pérdidas en la línea, las caídas de tensión y para aprovechar como potencia activa toda la potencia de alimentación de las instalaciones y para impedir que el factor de potencia (cos ϕ) disminuya a valores demasiado bajos, considerando también el hecho de que la compañía eléctrica penaliza los excesos de energía reactiva, de cualquier tipo, inductiva o capacitativa.

Una carga óhmica-inductiva absorbe de la red una corriente tanto más desfasada con relación a la tensión (cos ϕ bajo) cuanto más prevalece el efecto inductivo. A paridad de componente activa en fase con la tensión, la corriente en línea es tanto mayor cuanto mayor es el ángulo de desfase. Insertando un condensador en paralelo con la carga, éste suministra parte de la corriente reactiva solicitada por la carga: efectivamente, cuando el condensador se descarga, la parte inductiva de la carga se carga y viceversa, cuando la parte inductiva se descarga, ésta carga el condensador y, en consecuencia, se reduce la corriente suministrada por la línea que resulta menos desfasada con relación a la tensión.

Según la Norma IEC 70 y CEI, los condensadores han de poder funcionar en régimen con una corriente de valor eficaz hasta 1,3 veces la corriente asignada I_{cn} del condensador a causa de la posible presencia de armónicos en la tensión de red. La conexión de una batería de condensadores se puede comparar a un cierre en cortocircuito en el cual la corriente de cierre I_p asume valores de cresta elevados, especialmente cuando se insertan baterías de condensadores en paralelo con otras ya en tensión.

Estas condiciones de funcionamiento tienen que considerarse cuando se elija el interruptor automático (que deberá tener un poder de cierre adecuado), y cuando se regule el relé de sobrecorriente para evitar intervenciones intempestivas en el momento de insertar la batería de condensadores. Generalmente, la corriente asignada I_{ni} de los dispositivos de maniobra y, por lo tanto, también de los interruptores automáticos y de los correspondientes relés y cables de alimentación tiene que ser $I_{ni} = 1,43xI_n$ donde I_n es la corriente teórica calculada en función de la potencia de los condensadores sin tener en cuenta la presencia de armónicos. Para tener en cuenta la corriente de conexión de los condensadores, el umbral de intervención para la protección contra cortocircuito tiene que ser, como mínimo, igual a $10xI_{ni}$.

Cuando se utilizan baterias de condesadores para la compensación automática, la maniobra la realizan en general los contactores, mientras que los interruptores automáticos SACE Isomax S se pueden utilizar en función del número de maniobras y de la frecuencia de las mismas. A la tensión de servicio de 380/415 Vca, la protección de una batería de condensadores se efectúa con interruptores automáticos SACE Isomax S con modelos de S1 a S7, para corrientes de 10 hasta 1600 A; para una potencia máxima hasta 736 kVAR con el interruptor automático S7 1600 A.

En Baja Tensión, se utilizan normalmente condensadores trifásicos conectados en triángulo y dotados de resistencia de descarga. La compensación de reactiva puede ser:

– **Distribuida** en cada uno de los servicios y conectada a los mismos tanto directamente como con interruptores propios. Es el caso utilizado en grandes servicios (por ejemplo, grandes motores) y en el secundario de los transformadores de las sub-

estaciones de distribución para compensar exclusivamente la potencia magnetizante que es mayormente reactiva y es igual, mediamente, al 5% de la potencia asignada en kVA del transformador. El poder de corte del interruptor automático tiene que ser adecuado al número de los transformadores conectados en paralelo.

– **Parcializada**, realizada con unidades conectadas a los cuadros de los diferentes grupos de servicios. Se utiliza para instalaciones muy amplias y con varias subestaciones de transformación o distribución.
– **Centralizada**, realizada con equipos de compensación normalmente con regulación automática y mando automático y conectadas antes de todas las cargas que se desea compensar e inmediatamente después del punto de medición del cos f o cerca del cuadro general de baja tensión. Es el caso adoptado con más frecuencia y empleado para instalaciones de baja y media potencia con extensión limitada.
El número de las maniobras de los condensadores, al ser mandadas automáticamente, resulta muy elevado por lo que, generalmente, se emplean contactores especiales con resistencias de conexión.

La potencia de la batería de condensadores para obtener una determinada compensación depende de la potencia de la carga que se desea compensar, del cos ϕ inicial y del cos ϕ que se desea obtener.

Coeficiente para calcular la potencia de la batería de condensadores en kVAR/kW para elevar el valor de cosϕ.

El interruptor automático se emplea generalmente en versión tripolar, mientras que en la versión tetrapolar se utiliza cuando hay instrumentos y aparatos que utilizan también el neutro, como, por ejemplo, pequeños cuadros de compensación de reactiva. En dichos casos, puede ser oportuno prever la protección diferencial (para sistemas de distribución TT y TN-S) ya que la presencia del neutro indica la presencia de instrumentos accesibles a las personas.

Maniobra y protección de generadores trifásicos en c.a.

En los casos más frecuentes, el generador de baja tensión constituye la alimentación de emergencia de la red de alimentación normal y se activa cuando falta la tensión mediante sistemas de conmutación automática para garantizar la alimentación de la parte de instalación con servicios esenciales, sobre todo, si el corte de alimentación puede provocar situaciones de peligro para las personas afectadas, pérdidas de producción importantes o problemas significativos para la seguridad y la gestión de las instalaciones (señalizaciones, alarmas, sistema antiincendio, iluminación). Normalmente, el grupo de emergencia está formado por un motor diesel acoplado a un alternador de potencia limitada que no supera los 1000 kVA. Además, los generadores también son ampliamente utilizados en el sector naval.
Los interruptores automáticos en caja moldeada SACE Isomax S pueden utilizarse como interruptores de máquina y/o como interruptores de salida con relés de protección contra las sobrecorrientes, concretamente, los relés con microprocesador SACE PR211/P y PR212/P y los relés solo magnéticos con bajo umbral de intervención.
Al elegir el interruptor automático que se ha de utilizar hay que considerar la corriente asignada del generador (en función de la potencia generador y de la tensión de servicio) y la corriente de cortocircuito en el punto de aplicación que se puede calcular en función de la reactancia subtransitoria X"d(%) según la siguiente fórmula:

$$I_{cc} = \frac{P \times 100}{U_e \times X''d}$$

La corriente de cortocircuito del generador presenta, normalmente, valores muy limitados con relación a los de la red; asimismo hay que prestar una especial atención a las regulaciones de los relés de sobreintensidad para los cuales se han de prever regulaciones del elemento magnético entre 3 y 5 veces la corriente asignada, tanto si el interruptor automático se emplea como interruptor general del generador como si se emplea como interruptor de salida.
Si el generador funciona en paralelo con la red de alimentación normal, la corriente de cortocircuito que hay que tener en cuenta al elegir el interruptor automático es la debida a la subestación de transformación ya que asume un valor más elevado con relación a la debida eventualmente por un defecto alimentado por el generador. Para los interruptores automáticos insertados después del generador, el poder de corte se determina en función de la corriente de cortocircuito debida al número total de generadores de igual potencia que hay en paralelo menos uno.
La siguiente tabla permite elegir los interruptores automáticos de protección de los generadores trifásicos a 400 V - 50 Hz.

Potencia del generador	Corriente asignada	Interruptores automáticos											
[kVA]	[A]	S1 125	S2 160	S3 160	S3 250	S4 160	S4 250	S5 400	S5 630	S6 630	S6 800	S7 1250	S7 1600

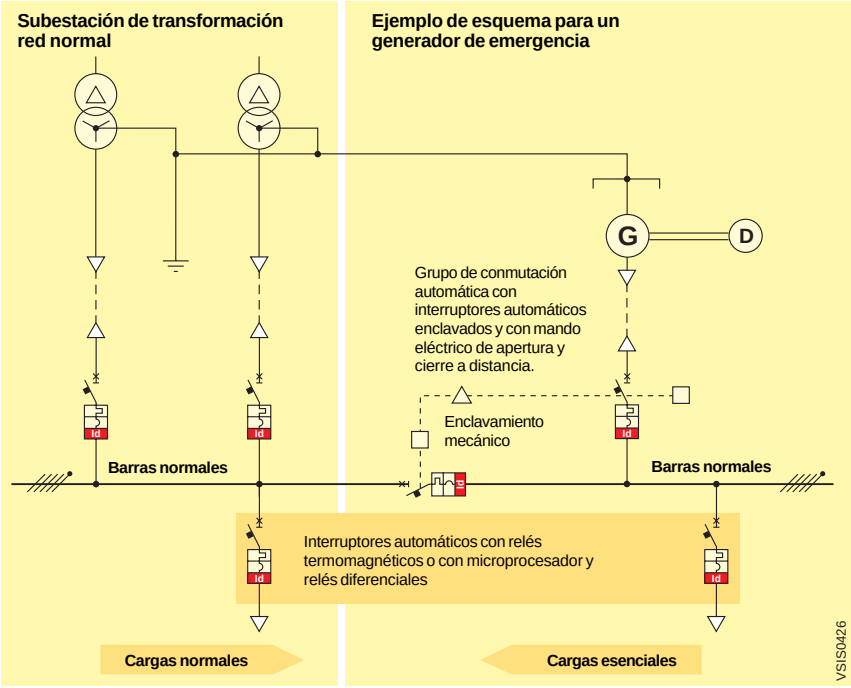
Al emplear los generadores como alimentación de emergencia es muy importante la elección del sistema de distribución (TT, TN e IT) ya que puede ser diferente para el funcionamiento normal y el de emergencia. Por ejemplo, podría haber un sistema TN-S para la red normal y un sistema IT para la red de emergencia con solamente el generador en servicio, que necesita la instalación de un dispositivo para controlar el aislamiento y la señalización del primer defecto a tierra de manera que se pueda intervenir para eliminar las causas y evitar las consecuencias de un eventual segundo defecto a tierra. Por lo tanto hay que prestar una especial atención al elegir el número de polos, los disparadores o relés de sobrecorriente y los diferenciales que han de garantizar las protecciones en ambos regímenes de funcionamiento.



Red de alimentación normal /de emergencia con enclavamiento y conmutación

1 **El número de polos** del interruptor automático depende del sistema de distribución (TT, TN e IT).

2 **El relé de protección** contra las sobrecorrientes: termomagnético para los interruptores automáticos S1, S2, S3, S5 y S6 y con microprocesador para los interruptores automáticos S4, S5, S6 S7, PR211/P o PR212/P, en versión LSI para realizar cadenas de selectividad con los interruptores automáticos situado aguas abajo, en versión LSIG para la protección contra los defectos a tierra en los casos en cuales ésta protección no se pueda efectuar con relés de protección contra las sobrecorrientes.

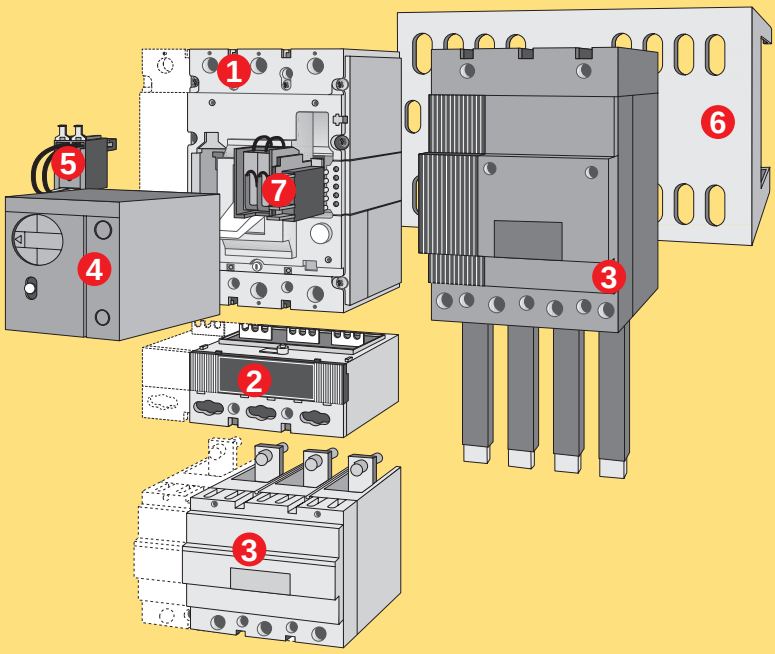
3 **Protección diferencial**, realizada con los relés SACE RC211 y RC212 para los interruptores automáticos tetrapolares S1, S2 y S3 o un relé diferencial de cuadro RCQ con transformador toroidal para los interruptores automáticos S4, S5, S6 y S7 para la protección contra los defectos a tierra en los casos en los cuales ésta no se puede efectuar con la función G del relé PR212. En general, la protección diferencial se utiliza en los sistema TT, TN-S e IT. Es preferible que el relé diferencial se inserte en el centro estrella del generador y la puesta a tierra del mismo cuando ésta se efectúa.

4 **Mando a distancia** para el arranque y la parada automática y en manual.

5 **Relé de apertura** a distancia con el correspondiente contacto de final de carrera para la inserción de todas las protecciones típicas del grupo diesel-alternador:
- lubricación, refrigeración, nivel del carburante y máxima temperatura
- relé indirecto de retorno de energía para un generador que funcione en paralelo con la red, para impedir que funcione como motor absorbiendo corriente en lugar de suministrarla
- relé indirecto de máxima y mínima frecuencia, relé indirecto de máxima y mínima tensión y eventual relé indirecto diferencial de sobreintensidad y apertura de emergencia.

6 **Enclavamiento mecánico** entre el interruptor automático del generador y el interruptor automático general de red de las cargas esenciales.

7 **Contactos auxiliares** para las señalizaciones o los enclavamientos, de insertado/extraído, abierto/cerrado o abierto por intervención del relé.



Corriente continua

Distribución en corriente continua

La corriente continua representa uno de los modos de distribución de energía eléctrica de las instalaciones eléctricas para industrias y sector terciario y requiere redes de distribución que satisfagan completamente las exigencias de coordinación de las protecciones, de flexibilidad, por ejemplo, para futuras ampliaciones, así como interruptores automáticos adecuados en cuanto a regulaciones, ejecuciones y prestaciones con corrientes de defecto.

CSIS9117

Alimentación de emergencia o de servicios auxiliares

El empleo de la corriente continua es debido a la necesidad de disponer de una fuente de energía de reserva que permita alimentar servicios esenciales como sistemas de protección, luces de emergencia, sistemas de alarma, circuitos de hospitales y fábricas, centros de cálculo, utilizando, por ejemplo, baterías de acumuladores, instaladas cerca de los servicios y alimentadas en tampón por la red, y caracterizadas en la mayoría de los casos por tensiones de servicio hasta 500 V y corrientes de defecto muy elevadas en proximidad de las fuentes de alimentación debido a la baja resistencia interna de las baterías. Constituyen la fuente de energía más segura para alimentar dichos servicios, tanto directamente en corriente continua como por medio de grupos de continuidad UPS cuando la alimentación de las cargas es en corriente alterna.

CSIS9115

Tracción eléctrica

Las ventajas en cuanto a la regulación de la velocidad ofrecidas por el empleo de motores en corriente continua y la alimentación mediante línea de contacto única hacen que la alimentación en corriente continua sea la solución más adoptada para ferrocarriles, metro, tranvías, ascensores y medios de transporte en general. Las aplicaciones típicas de los interruptores automáticos son la protección de las líneas y de los dispositivos, la maniobra de motores y el accionamiento. Se caracterizan por tensiones de servicio hasta 1000 V con posibles sobretensiones transitorias, corrientes variables frecuentemente en relación con las condiciones de servicio, corrientes de cortocircuito elevadas, exposición a condiciones ambientales agresivas en presencia eventualmente de golpes y vibraciones.

CSIS9116

Instalaciones industriales especiales

Pueden ser instalaciones para procesos electrolíticos o bien aplicaciones en las cuales se presentan especiales exigencias de servicio de las máquinas eléctricas como pueden ser las necesidades de una rápida amortiguación de la corriente en su circuito de excitación. En dichas condiciones, la tensión puede alcanzar picos 5-10 veces el valor de ejercicio normal y la corriente puede superar incluso 3 o 4 veces los valores nominales de excitación.

Poder de corte en kA en corriente continua y número de polos a conectar en serie.

Las corrientes de defecto en corriente continua son, normalmente, muy elevadas cerca de las fuentes de alimentación debido a la baja resistencia interna de las baterías. A diferencia de la corriente alterna para la cual existe un natural paso por cero en cada semiperiodo y al cual le corresponde un apagado del arco que se forma durante la apertura del circuito, en corriente continua, para garantizar el apagado del arco, hay que forzar el paso de la corriente por el cero. El corte del paso de corriente puede provocar picos de tensión que dependen, básicamente, de la falta de disipación de la energía electromagnética acumulada en el circuito y pueden favorecer el cebado del arco.

Estos fenómenos de naturaleza energética dependen especialmente del nivel de tensión de servicio de la instalación y obligan a instalar los interruptores automáticos según unos esquemas de conexión en los cuales los polos del interruptor automático se encuentran conectados en serie con lo que se mejoran las prestaciones en cortocircuito ya que el poder de corte del interruptor automático resulta mayor cuanto mayor es el número de contactos que abren el circuito a la máxima tensión de servicio de la instalación.

Esto significa que, al aumentar la tensión, hay que aumentar el número de los cortes de corriente en serie para obtener un número de polos para el corte adecuado al nivel de defecto.

En estos casos, es necesario disponer de interruptores automáticos como SACE Isomax S que aseguran:

– rápida intervención con adecuado poder de corte;
– elevada capacidad de limitar la corriente de defecto y de contener el efecto térmico y el electrodinámico debido al cortocircuito
– contención de las sobretensiones
– relés de tipo termomagnético de bimetal adecuados al funcionamiento en corriente continua.

Cómo elegir los interruptores

Los interruptores automáticos SACE Isomax S ofrecen una gama completa en corriente continua para corrientes de servicio de 10 a 800 A. La elección del interruptor automático depende de los datos principales de la instalación, a saber:

– la corriente de servicio en función de la cual se determina el modelo del interruptor automático (SACE S1, S2, S3, S4, S5 y S6) y la regulación para el relé de sobrecorriente termomagnético que se tiene que montar en el interruptor automático
– la corriente de cortocircuito prevista en el punto de instalación del interruptor automático de la cual depende la elección de la versión del interruptor automático en cuanto a las prestaciones en cortocircuito (B, N, S, H y L);
– la tensión de servicio U_b en función de la cual se determina el número de polos a conectar en serie;
– el esquema de conexión del interruptor automático del cual depende el número de polos del interruptor automático.

Para conectar el interruptor es necesario, por lo tanto, definir el esquema de conexión del interruptor a la red que depende esencialmente de:

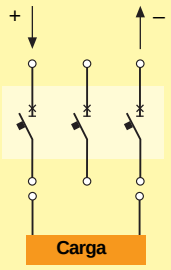
– el número de polos a conectar en serie;
– el tipo del sistema de distribución que puede ser aislado de tierra, con una polaridad a tierra, o con el punto medio de la alimentación a tierra;
– del tipo de defecto contra el cual hay que proteger la red; en una instalación de corriente continua se pueden producir dos tipos de defecto:
  Defecto franco entre las polaridades: representa el caso más peligroso en términos de nivel de defecto en función del cual hay que elegir el poder de corte del interruptor automático.
  Defecto polaridad-masa: la influencia de este tipo de defecto depende esencialmente del tipo de red de distribución. Puede no tener influencia en la protección si la polaridad implicada está ya conectada a tierra (red con polaridad a tierra) o aislada de tierra (red aislada), mientras puede ser interesante la protección de sobrecorriente si la polaridad implicada se trata de la polaridad no a tierra (red con polaridad a tierra o con punto medio a tierra) o si se producen simultáneamente defectos a tierra de ambas polaridades (red aislada).

Los esquemas de conexión

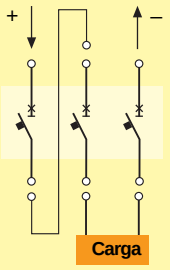
Para obtener el número de polos en serie necesario para garantizar el poder de corte requerido en las diferentes tensiones de funcionamiento tienen que utilizarse esquemas de conexión adecuados.

Protección y seccionamiento del circuito con interruptores automáticos tripolares

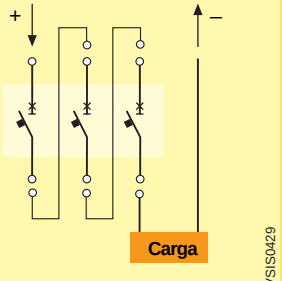
Esquema A: corte con 1 polo por polaridad



Esquema B: corte con 2 polos en serie para una polaridad y 1 polo para la otra polaridad

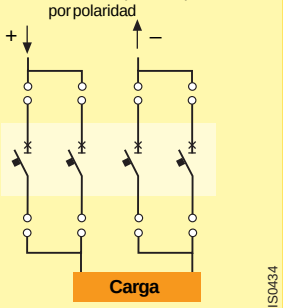


Esquema C: corte con 3 polos en serie por polaridad

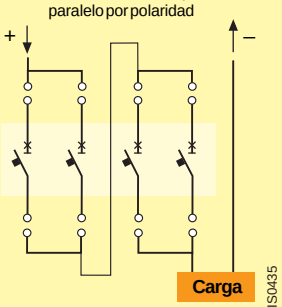


Polos en paralelo

Esquema D: corte con 2 polos en paralelo por polaridad

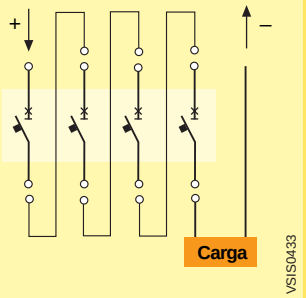


Esquema E: corte con serie de 2 polos en paralelo por polaridad

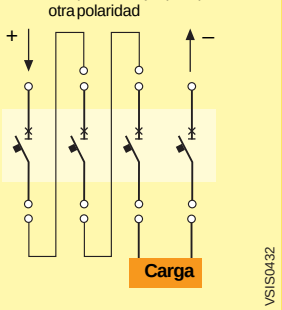


Empleo a 1000 Vcc con interruptores automáticos tetrapolares

Esquema F: corte con 4 polos en serie para una polaridad

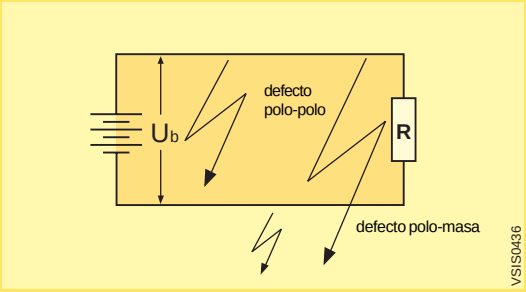


Esquema G: corte con 3 polos en serie para una polaridad y 1 polo para la otra polaridad



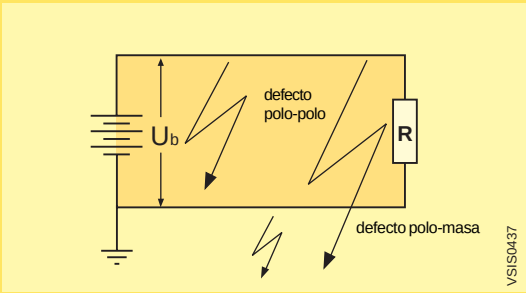
La elección del sistema de conexión adecuado depende del tipo de red de distribución.

Red con ambas polaridades aisladas de tierra



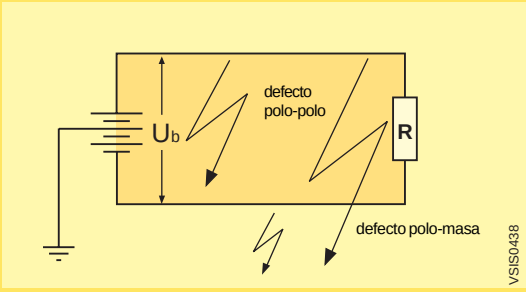
Ningún punto de la red de distribución está conectado a tierra.
El defecto franco entre las dos polaridades establece una corriente de cortocircuito a la cual contribuyen ambas polaridades con una tensión plena U_b y en función de la cual hay que elegir el poder de corte del interruptor automático.
Los defectos entre cada polaridad y la tierra, si no se producen simultáneamente, no tienen consecuencias desde el punto de vista del funcionamiento de la instalación mientras que, si se producen simultáneamente, significa que hay un defecto de tipo franco entre los polos.
El interruptor automático tiene que conexionarse distribuyendo los polos necesarios al corte en ambas polaridades. Sin embargo, para garantizar el seccionamiento, es indispensable que ambas polaridades se interrumpan.
Con este sistema es oportuno prever en la instalación un relé para señalar el defecto a tierra o la disminución del aislamiento hacia tierra de una polaridad de manera que se pueda eliminar inmediatamente y, en consecuencia, se pueda evitar que un sucesivo defecto a tierra en la otra polaridad provoque problemas de servicio totales debidos a la intervención de los relés del interruptor automático tras el cortocircuito que, en dichos casos, se produce entre las dos polaridades a través de la tierra.

Red con una polaridad a tierra



Se conecta a masa una de las dos polaridades.
El defecto franco entre las dos polaridades establece una corriente de cortocircuito a la cual contribuyen las dos polaridades con tensión plena U_b y en función de la cual hay que elegir el poder de corte del interruptor automático.
El defecto hacia masa de la polaridad no conectada a tierra establece una corriente que puede afectar las protecciones de sobrecorriente en función de la resistencia de tierra. El defecto hacia masa de la polaridad puesta a tierra no tiene consecuencias desde un punto de vista del funcionamiento de la instalación.
Por estas razones, con miras a la protección, es suficiente instalar el interruptor automático solamente en la polaridad aislada de tierra. Si se desea obtener también el seccionamiento, es necesario prever un polo de corte suplementario en la polaridad a masa.

Red con punto medio de la fuente de alimentación conectado a tierra



El defecto franco entre las dos polaridades establece una corriente de cortocircuito a la cual contribuyen las dos polaridades con tensión plena U_b. Los defectos de una polaridad hacia la masa establecen una corriente de defecto a una tensión igual a ½ U_b hacia la cual hay que proteger el circuito. Para proteger el circuito hacia este tipo de defecto, el interruptor automático tiene que conexionarse obligatoriamente en las dos polaridades. Pero, debido al nivel de defecto es posible repartir en cada polaridad los polos necesarios para cortar la sobreintensidad de cortocircuito a la tensión de ½ U_b. Esto garantiza la protección tanto en el caso de defecto franco entre dos polaridades como en el caso de defecto de una polaridad hacia la masa. De esta manera se asegura el seccionamiento del circuito.

En la siguiente tabla se indica qué esquema de conexión hay que adoptar en función del número de polos a conectar en serie para obtener el poder de corte requerido en función del tipo de red de distribución.

		Red aislada de tierra	Red con una polaridad a tierra	Red con punto medio a tierra
2 polos en serie	Protección	–	E (4p)	–
	Protección y Seccionamiento	A (3p) - D (4p)	B (3p)	A (3p)
3 polos en serie	Protección	–	C (3p)	–
	Protección y Seccionamiento	B (3p)	F (4p)	G (4p) - B (3p)

Esquema de conexión en función de la red de distribución

Los esquemas de conexión D y E se utilizan exclusivamente con el interruptor automático SACE S6 630 y S6 800 y permiten conectar en paralelo dos polos del interruptor automático para aplicaciones con corriente de servicio de 800 a 1440 A. Las conexiones externas a los terminales del interruptor automático tienen que ser realizadas por el usuario de manera que se consiga el perfecto equilibrio de la conexión que garantice el balance en la distribución de la corriente que circule en cada polo. En estas condiciones se pueden tener en cuenta los factores de equivalencia con la regulación en c.a. descritos a continuación. La capacidad de conducción de corriente del interruptor automático se calcula mediante la siguiente fórmula:

$$In_{(2\ polos\ en\ paralelo)} = (I_{th} \times 2) \times 0,9$$

con regulación de 0,7 a 1. Por lo tanto, con dos polos en paralelo, el interruptor automático SACE S6 630 puede utilizarse en el campo de 800 a 1100 A mientras que el interruptor automático SACE S6 800 puede utilizarse en el campo de 1000 a 1440 A.
Los esquemas de conexión F y G requieren el empleo de interruptores automáticos tetrapolares con el neutro al 100% de la regulación de las fases y pueden utilizarse con los interruptores SACE S3, S5 y S6 para tensiones superiores a 750 V y hasta 1000V. Para mayor información, diríjase directamente a ABB SACE.
Los relés de sobreintensidad termomagnéticos para c.a. son adecuados para emplearse en c.c. teniendo en cuenta que los valores de intervención del elemento térmico corresponden a los indicados para el funcionamiento en. c.a. mientras que el umbral de intervención del elemento magnético tiene que regularse considerando que la intervención se produce a un valor superior con respecto al análogo caso en c.a. debido a los fenómenos magnéticos. En la siguiente tabla, para cada interruptor automático se indica el valor de corrección a adoptar para los umbrales de protección.

Interruptor	Esquema A	Esquema B	Esquema C
S1	k_m= 1,3	k_m= 1	k_m= 1
S2	k_m= 1,3	k_m= 1	k_m= 1
S3	k_m= 1,3	k_m= 1,15	k_m= 1,15
S5	k_m= 1,1	k_m= 1	k_m= 1
S6	k_m= 1,1	k_m= 1	k_m= 1

1 **El numero de polos del interruptor automático** depende del tipo de red de distribución. Se pueden utilizar los interruptores automáticos SACE S1, S2, S3 S4, S5 y S6.

2 **El relé de sobreintensidad** es de tipo termomagnético.

3 **Contactos auxiliares** para las señalizaciones o los enclavamientos de insertado/extraído, abierto/cerrado o abierto por intervención del relé.

4 **Relé de apertura** a distancia con el correspondiente contacto de final de carrera a utilizar como apertura de emergencia para la línea de alimentación general o bien como mando a distancia de apertura y cierre para el telemando o en el caso que se tenga que realizar una conmutación automática.

5 **Enclavamiento mecánico** entre interruptores automáticos como en el caso de dos interruptores de una conmutación automática para garantizar que la fuente de alimentación normal y la de emergencia no puedan funcionar en paralelo.

El factor de corrección para el elemento magnético cuando el interruptor automático se utiliza en c.c. significa que para el mismo ajuste, en c.c. aumenta el valor de la corriente de intervención del elemento magnético respecto a la corriente de intervención en c.a.
Conocido el valor de la corriente de intervención hay que adecuar el ajuste del elemento magnético al valor de ajuste corregido para c.c.

Por ejemplo:
- Corriente de servicio: Ib = 600 A
- Protección magnética deseada: Im = 5000 A
- Ajuste del umbral magnético:

$$\text{ajuste} = \frac{I_m}{k_m \times I_n}$$

therefore in this specific case, having chosen circuit-breaker S6 R630 (In = 630 A), the magnetic threshold setting value will be:

$$\text{ajuste} = \frac{5000}{1{,}1 \times 630} \approx 7$$

Protección contra defectos a tierra

Los contactos directos e indirectos

La protección contra los contactos directos o indirectos entra en el tema general de la seguridad y tiene una importancia fundamental si se piensa, por ejemplo, que el contacto entre las personas y los aparatos eléctricos es inevitable. El tema está regulado por la ley y por las normas que establecen unos requisitos mínimos indispensables para evitar y/o prevenir accidentes. Pero, por su naturaleza, la seguridad no puede limitarse a los requisitos mínimos, especialmente por el hecho de que la explotación de las instalaciones y el uso de los dispositivos existentes en las mismas comporta un cambio continuo del estado de la instalación. El contacto contra partes bajo tensión puede provocar el paso de una corriente a través del cuerpo de la persona con consecuencias incluso mortales. Los sistemas de protección permiten reducir la exposición a dicho peligro, limitando la corriente y el tiempo durante el cual puede pasar dicha corriente. Además, es necesario que el sistema de protecciones ofrezca garantías incluso contra los fenómenos evolutivos que afectan a la instalación durante el ciclo de vida de la misma.

Convencionalmente (Norma CEI 64-8/410), se distingue entre:

– contactos directos, cuando se puede entrar en contacto con una parte de la instalación normalmente bajo tensión
– contactos indirectos, cuando se produce el contacto con partes que normalmente no están bajo tensión durante un defecto de aislamiento.

Las Normas CEI 11-8/3.1.14 - CEI 64-8/481.2.3 CEI 64-8/410 prevén obligatoriamente:

– una medida de protección contra los contactos indirectos tanto en los “locales normales” como en los “locales eléctricos”
– una medida de protección “total” contra los contactos directos en cualquier local que no sea un “local eléctrico”.

La protección contra los contactos directos tiene que efectuarse mediante aislamientos, envolventes o barreras que impidan el contacto con partes bajo tensión. La protección contra los contactos indirectos de una persona que entre en contacto con una masa metálica que se haya puesto bajo tensión debido a un defecto, como por ejemplo, el deterioro del aislamiento, se realiza mediante dispositivos de corte automático, de sobreintensidad o diferenciales. Utilizando un interruptor automático con relé de protección es posible proteger conductores de longitud elevada contra los contactos indirectos disminuyendo el umbral de intervención de la protección magnética contra cortocircuito, mientras que el uso de dispositivos diferenciales hace que la protección contra contactos indirectos sea independiente del tipo de instalación.

	Las prescripciones de la Norma CEI 64-8
TT	Para efectuar la protección mediante dispositivos de sobrecorriente a tiempo inverso tiene que satisfacerse la siguiente relación: **$Rt \leq 50 / I$** en la cual: – I es la corriente de intervención en 5 s del dispositivo de protección – Rt es la resistencia de la instalación de tierra en condiciones más desfavorables
TN	Para efectuar la protección mediante dispositivos de sobreintensidad a tiempo inverso o dispositivos diferenciales, es necesario que en cualquier punto del circuito se satisfaga la siguiente relación: **$I \leq Uo / Zg$** en la cual: – Uo es la tensión a tierra de la instalación – Zg es la impedancia del anillo de defecto para defecto franco a masa – I es la corriente de intervención en 5 s del dispositivo de protección
IT	La tensión en las masas tiene que superar el valor de 25 V en el caso de primer defecto a tierra mientras que en el caso de segundo defecto a tierra la intervención del dispositivo de protección tiene que intervenir en 5 s. En caso de un único defecto a tierra, la corriente de defecto está fuertemente limitada por la capacidad de la línea hacia tierra y, por lo tanto, no se requiere el corte, sino la señalización para evitar riesgos debidos al segundo defecto a tierra.

Tabla de las prescripciones Norma CEI

La protección diferencial

Los interruptores diferenciales se emplean tanto para la protección de las personas como para la protección contra los defectos a tierra. La protección diferencial se admite como protección contra los contactos indirectos ya que consiente eliminar un defecto mientras se admite únicamente como protección adicional contra los contactos directos de una persona que entre en contacto con los conductores activos de un circuito eléctrico ya que no puede garantizar la protección de las personas en caso de:

– persona aislada de tierra que toca simultáneamente dos conductores activos; en dicho caso, la corriente de defecto se cierra a través de la persona y es defectada por el dispositivo diferencial;
– persona en contacto con el terreno que toca simultáneamente dos conductores activos; en dicho caso, la corriente de defecto se cierra en parte a través de la persona y en parte a través del terreno y es solamente ésta la que defecta el dispositivo diferencial que, por lo tato, no puede garantizar la protección de la persona.

Se encuentran disponibles:

– los relés diferenciales SACE RC211 y RC212 para el montaje lateral o vertical con los interruptores SACE S1, S2 y S3 en versión fija tetrapolar, utilizables para valores de corriente I_{Δ} a partir de 30 mA hasta 3A y retardos de tiempo programables hasta 1,5 s con el relé diferencial RC212;
– el relé diferencial de cuadro SACE RCQ con transformador toroidal separado (abribles y cerrados), combinable con todos los interruptores automáticos de S1 a S7, se puede utilizar para valores de corriente I_{Δ} a partir de 30 mA hasta 30 A y retardos de tiempo que se pueden programar hasta 5 s.

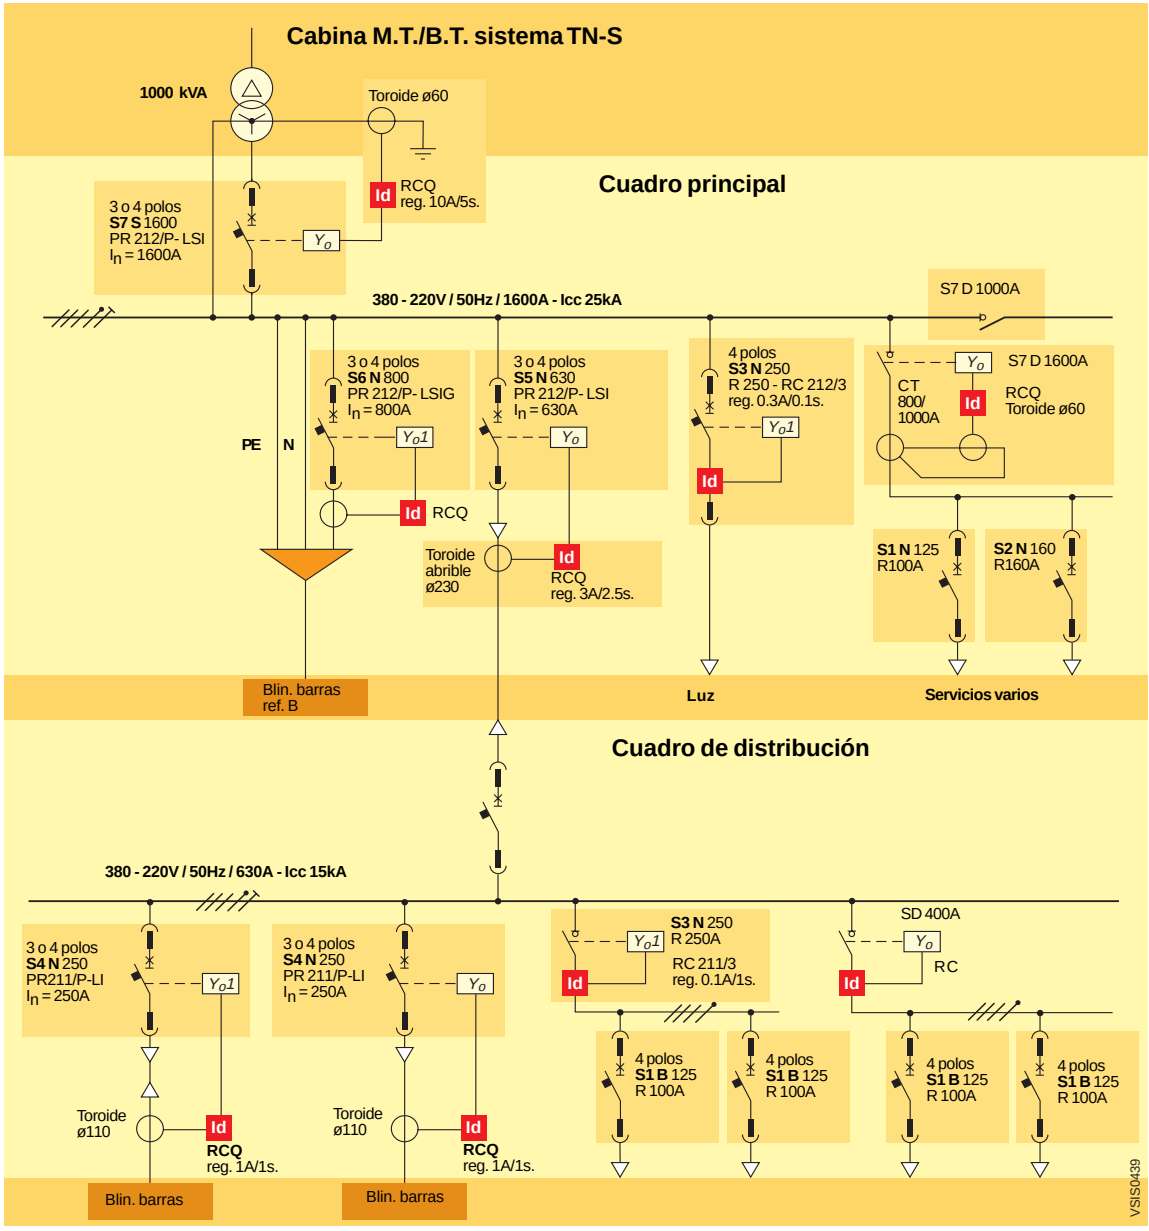
Las condiciones de corte por defecto a masa tienen que coordinarse con el valor de la resistencia de tierra en las instalaciones de tipo TT y con el valor de la impedancia del anillo de defecto en una instalación de tipo TN, con el objetivo de evitar que la tensión de contacto alcance valores superiores a los de la curva límite de seguridad y, concretamente, permanezca en valores superiores a 50 V por un tiempo superior a 5 s.

Además, la protección diferencial es seguramente la más eficaz contra los incendios debidos a causas eléctricas. Dicha protección detecta efectivamente los valores más bajos de las corrientes de defecto a tierra compatibles con las exigencias de funcionamiento de la instalación. Las más pequeñas corrientes de dispersión a tierra son, a menudo, peligrosas porque el arco eléctrico que se puede crear en el caso de un contacto a tierra discontinuo, puede provocar pequeños focos de incendios que al inicio son difíciles de detectar pero que al persistir pueden tener graves consecuencias.

En la instalación	Protección diferencial
Considerando que para los dispositivos normales de protección a tiempo inverso, el valor de la corriente a la cual corresponde el tiempo de intervención de 5 s está comprendido, orientativamente, entre 3 y 6 veces la In, las situaciones en las cuales la protección contra los contactos indirectos puede obtenerse con los dispositivos de protección contra sobreintensidad son muy raras. Además, al aumentar la potencia empleada, el valor de la resistencia del electrodo de la pica de tierra tendría que disminuir hasta el punto de hacer impracticable esta vía.	**PRÁCTICAMENTE NECESARIA** Tiene que prestarse atención en los casos en los cuales después de la protección diferencial, el neutro se pone a tierra. Dicha conexión transforma el sistema de TT a TN y un defecto a tierra del neutro no se detecta y puede permanecer por mucho tiempo.
Para los circuitos de distribución se admiten tiempos de intervención de las protecciones hasta 5 s. Con este tipo de sistema, la ventaja es la de poder utilizar los dispositivos de sobreintensidad para la protección contra los contactos indirectos. La práctica sugiere realizar una conexión equipotencial para reducir la tensión de contacto y aprovechar dicha ventaja. La protección diferencial es aconsejable cuando: – la impedancia del anillo de defecto después del punto en cuestión no se conoce o es difícil de determinar – existe el peligro de rotura del conductor de tierra o de protección – cables de longitud considerable – masas lejanas no interconectadas – se cambia el sistema de neutro.	**ACONSEJADA** a condición de que no se use en los sistemas TN-C y que no emplee un conductor PEN después de los dispositivos diferenciales en los sistemas TN-C. Con los dispositivos diferenciales, se obtiene una mayor seguridad ya que las elevadas corrientes de defecto, típicas de los sistemas TN provocan la intervención en un tiempo comprendido entre 30 y 40 ms, con lo cual se pueden tolerar tensiones hasta 280 V.
En presencia de doble defecto a masa, resulta difícil establecer la impedancia del anillo de defecto que comprende de los bobinados de fase del transformador de alimentación, los conductores de la dos fases a masa y una porción de los conductores de tierra. De esto deriva la dificultad de verificar que el defecto se pueda eliminar en menos de 5 s y, en consecuencia, la necesidad de recurrir en la casi totalidad de los casos al empleo de dispositivos de tipo diferencial.	**OPCIONAL** En los sistemas de tipo IT, la protección diferencial de los servicios es eficaz en el caso de una fase a tierra.

La función “G” de protección contra defectos a tierra

El defecto a tierra, originado normalmente por un defecto del aislamiento, provoca una corriente definida convencionalmente de defecto a tierra. La corriente de defecto a tierra tiene un carácter evolutivo y puede provocar un defecto franco fase-masa (cortocircuito monofásico).
En los interruptores automáticos SACE S4, S5, S6 y S7, la protección contra los defectos a tierra puede obtenerse también mediante la función “G” utilizando los relés de sobreintensidad con microprocesador PR212/P - LSIG. La regulación de 0,2 a 1 x In permite abarcar un campo de aplicaciones desde I_{Δ} de 20 A con el interruptor automático SACE S4 hasta 1600 A con el interruptor automático SACE S7. El retardo de la intervención se puede programar entre 0,1 y 0,8 s y permite realizar cadenas de selectividad con los relés diferenciales situados después e incluso con los interruptores automáticos instalados en el mismo cuadro.
El empleo de estos interruptores permite, por lo tanto, satisfacer las exigencias de protección contra los defectos a tierra hasta la subestación de transformación donde es necesario, primordialmente, la protección contra los grandes defectos a tierra.



Protección diferencial en un sistema TN-S

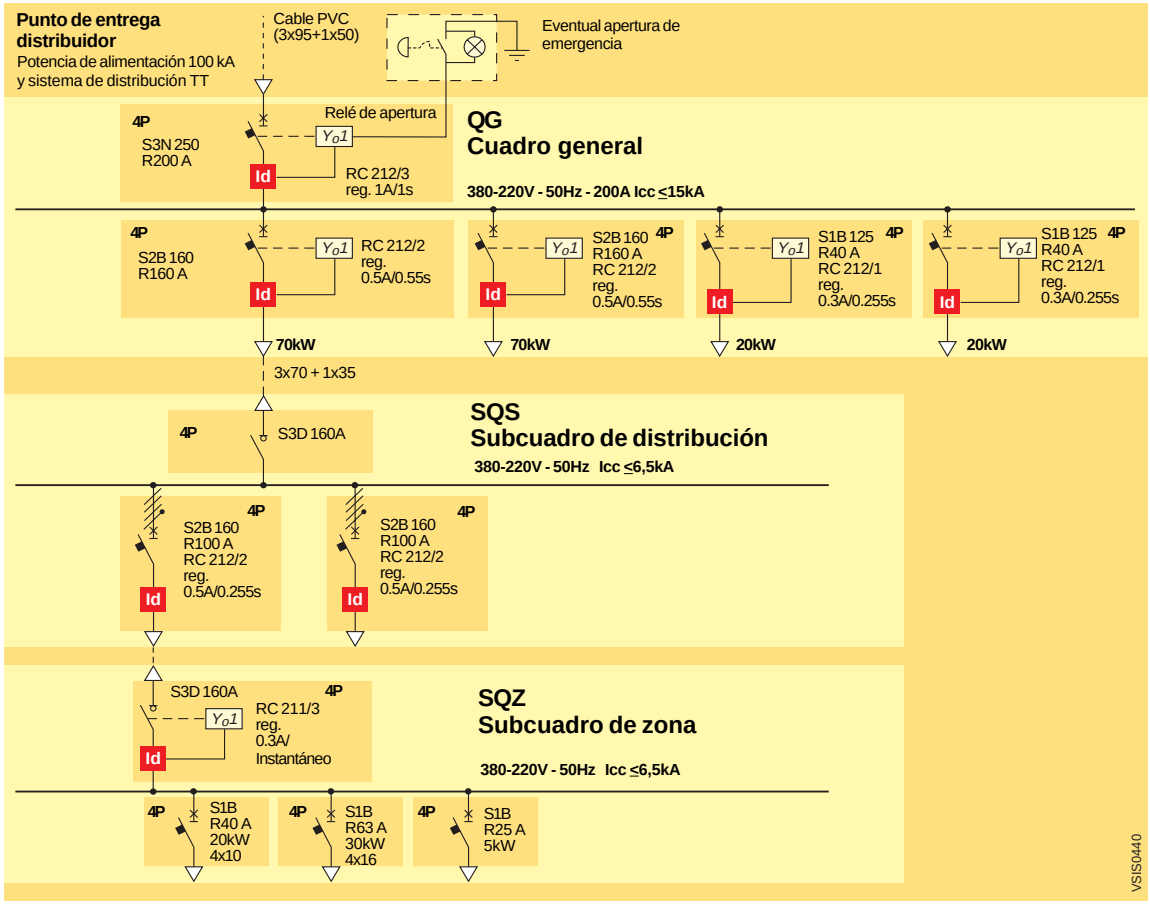
Selectividad entre dispositivos diferenciales

Para garantizar la continuidad de servicio, especialmente en las instalaciones en las que es indispensable por motivos de seguridad, como en los hospitales y en algunas instalaciones industriales, es necesario realizar la selectividad entre los dispositivos conectados en serie entre sí situados en los diferentes puntos de la instalación. En función del tipo de instalación, el sistema de protección diferencial puede realizarse para garantizar:

– un cierto nivel de selectividad horizontal, insertando dispositivos de protección diferencial en las diferentes derivaciones principales situadas después del interruptor automático general de manera que un eventual defecto a tierra no provoque la puesta fuera de servicio de toda la instalación;
– la selectividad vertical cuando el interruptor automático general también es interruptor diferencial; en dicho caso, la corriente diferencial asignada de intervención del interruptor general tiene que ser, como mínimo, el doble de la corriente de intervención de los dispositivos diferenciales situados después para garantizar una selectividad parcial amperimétrica o bien emplear interruptores diferenciales retardados para poder realizar una selectividad diferencial cronométrica; para ello, se puede utilizar en los interruptores automáticos S4 a S7 la función “G” de protección contra defecto a tierra con los relés a microprocesador SACE PR212/P - LSIG.

En general, la regulación del retardo del dispositivo diferencial aguas arriba tiene que ser superior al tiempo total de corte de los interruptores diferenciales situados después, considerando que el retardo máximo en los circuitos terminales de la distribución puede llegar hasta 1 s. La regulación de la corriente del dispositivo diferencial anterior tiene que ser, como mínimo, dos veces la del dispositivo diferencial en serie situado inmediatamente después con el cual se desea obtener la selectividad.

El relé diferencial SACE RC212, la función “G” de los relés SACE PR212/P-LSIG y el relé diferencial de cuadro SACE RCQ permiten realizar cadenas de selectividad diferencial cronométrica y amperimétrica utilizando, aguas abajo de los mismos, dispositivos oportunamente regulados y el relé diferencial con intervención instantánea SACE RC211.



Protección diferencial en el sistema de distribución TT

Interruptores para utilización a 400 Hz

Los interruptores de fabricación normal pueden utilizarse en corriente alterna con frecuencias mayores con relación a los 50-60 Hz para las cuales se han regulado las corrientes y los tiempos de intervención. A frecuencias elevadas, las prestaciones se reclasifican para tener en cuenta fenómenos típicos como:

– el aumento del efecto skin o pelicular y el aumento de la reactancia inductiva directamente proporcional a la frecuencia que, a igual sección del cobre, comportan una disminución de la conductividad y un aumento de los fenómenos de inercia que causan un recalentamiento de los conductores o de las piezas de cobre que en un interruptor automático están normalmente atravesadas por corriente;
– el ciclo de histéresis se alarga y disminuyen la saturación magnética y las fuerzas electromotrices inducidas por el campo magnético que se generan a una cierta corriente.

Por lo tanto, en general, estos fenómenos repercuten en el comportamiento de las partes de cobre tanto de los relés termomagnéticos como de las partes de interrupción de un interruptor automático, introduciendo la necesidad de reclasificar las prestaciones de los interruptores por cuanto concierne a las características de intervención de los relés. También en presencia de relés de sobreintensidad con microprocesador SACE PR211/P, que en general poseen una estabilidad de comportamiento ante las variaciones de frecuencia, hay que tener en cuenta estos fenómenos debido a las partes de cobre del interruptor automático y debido al aumento de la temperatura como resultado de la frecuencia.

Relés de sobreintensidad con microprocesador

Para el empleo a 400 Hz, los interruptores automáticos SACE S4, S5 , S6 y S7 pueden dotarse con relés de sobreintensidad con microprocesador SACE PR211/P. Los umbrales de intervención de la protección contra sobrecorriente tienen que regularse según los intervalos indicados en la tabla para tener en cuenta los fenómenos relacionados con la conductividad de las partes de cobre y del hecho de que los relés con microprocesador no son sensibles a la frecuencia.
Con la utilización a 400 Hz, se modifican los intervalos de tolerancia en los tiempos de intervención correspondientes a los umbrales de intervención de la función L de protección contra la sobrecarga (+10%).

Interruptores		**L**		**I**
	In[A]	regulación	I1 (400 Hz)	regulación

S6 630	630	0,4 ... 0,8	252 ... 504	1,5 ... 12
S6 800	800	0,4 ... 0,8	320 ... 640	1,5 ... 12
S7 1250	1250	0,4 ... 0,8	500 ... 1000	1,5 ... 12
S7 1600	1600	0,4 ... 0,8	640 ... 1280	1,5 ... 12

Relés de sobreintensidad termomagnéticos

El umbral de intervención del elemento térmico disminuye al aumentar la frecuencia a causa de la reducida conductividad de los materiales y del aumento de los fenómenos térmicos relacionados. En cambio, el umbral de intervención magnética aumenta al aumentar la frecuencia debido a los pequeños campos magnéticos inducidos.
En las siguientes tablas se resumen las prestaciones a la frecuencia de 400 Hz de los interruptores automáticos SACE Isomax S con los relés termomagnéticos o solo magnéticos.
Cuanto indicado en la tabla significa que a igual regulación, respecto a la frecuencia de 50/60 Hz, disminuyen los valores de intervención térmica y aumentan los valores de las corrientes de intervención magnética o, viceversa, tras determinar el valor de intervención térmica y magnética hay que ajustar los umbrales de intervención según las escalas de fondo reclasificadas.

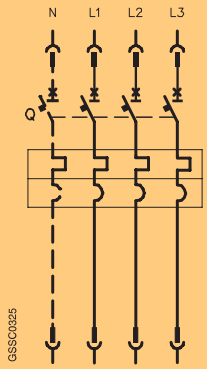
Esquemas eléctricos.
Estado de funcionamiento representado

El esquema se representa en las siguientes condiciones:
– interruptor en ejecución fija enchufable o extraíble (en función del tipo de interruptor), abierto e insertado
– circuitos sin tensión
– relés no intervenidos
– mando a motor con resortes cargados (para interruptores S6-S7).

El interruptor sólo está dotado con las aplicaciones especificadas en la confirmación de pedido de ABB SACE. Para redactar el pedido, consultar el presente catálogo.

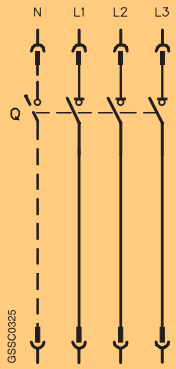
SACE S1-S2-S3-S5-S6

Interruptor tripolar o tetrapolar con relé termomagnético



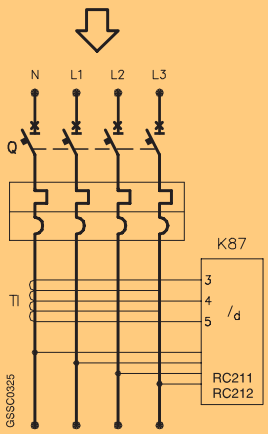
SACE S3D-S6D-S7D

Interruptor de maniobra-seccionador tripolar o tetrapolar

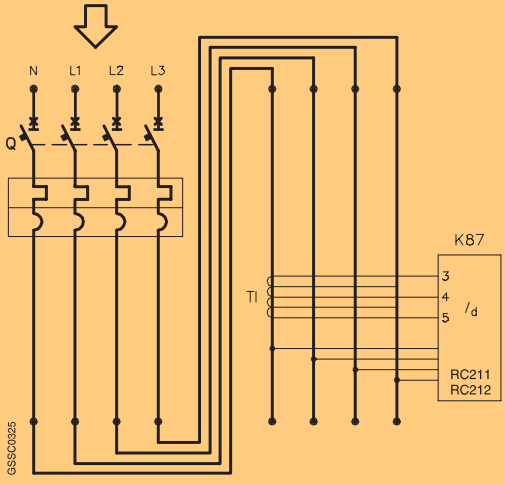


SACE S1-S2-S3

Interruptor tetrapolar en ejecución fija con relé diferencial en la parte inferior SACE RC211 o RC212



Interruptor tetrapolar en ejecución fija con relé diferencial colateral SACE RC211 o RC212



SACE S4-S5-S6-S7

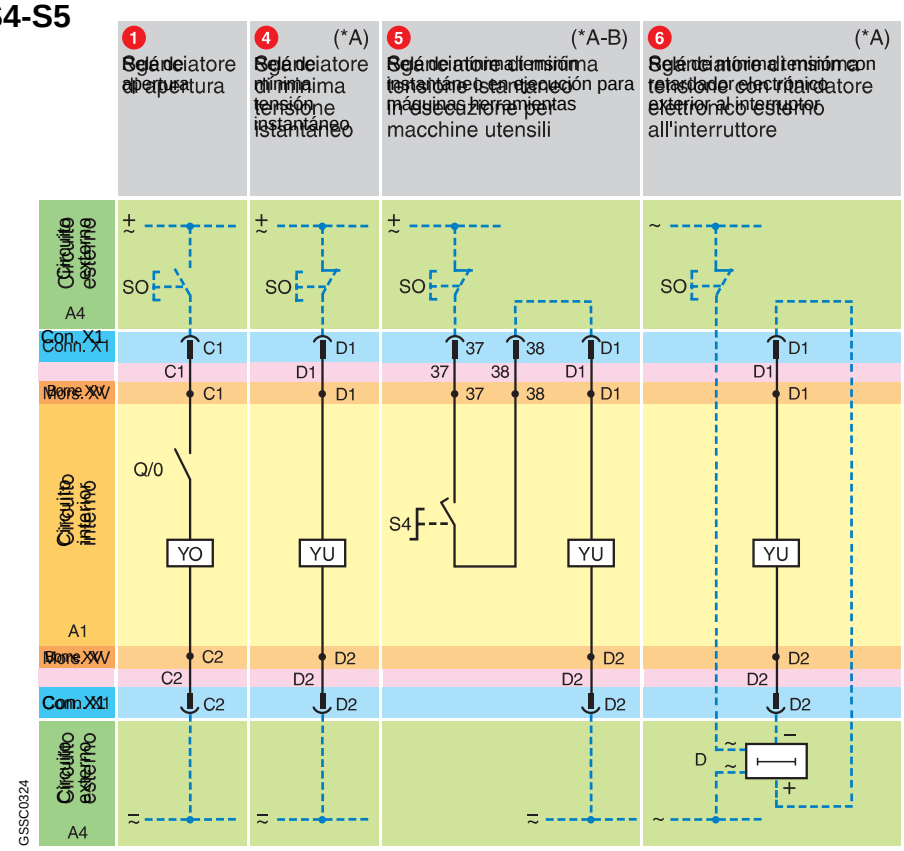
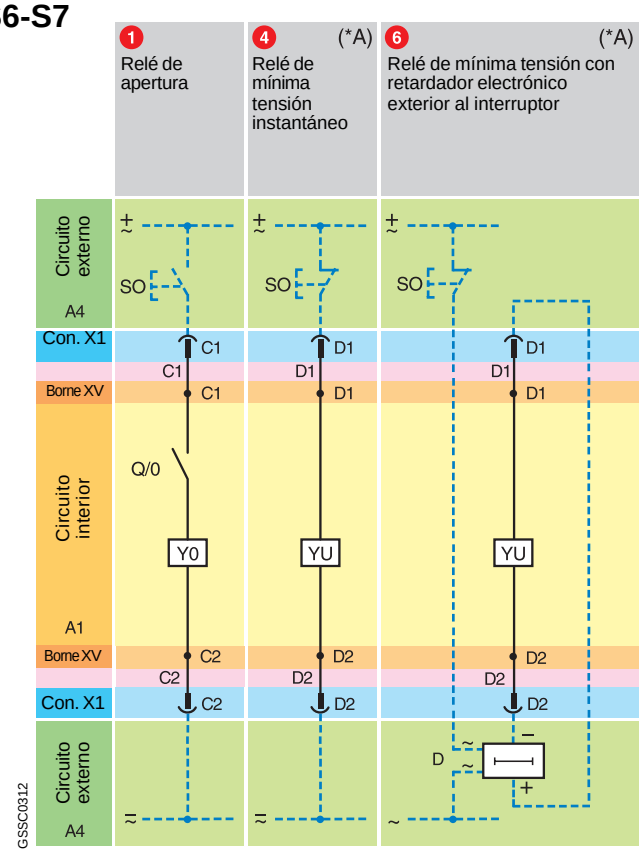
SACE S4-S5



SACE S6-S7



Incompatibilidad

No se pueden suministrar simultáneamente en el mismo interruptor los circuitos indicados con las siguientes figuras:

1 - 4 - 5 - 6 2 - 3

Disponibilidad

Para interruptores S1 - S2 los conectores X1 y X2 sólo se suministran si se solicitan

Notas

(*A) El relé de mínima tensión se suministra para alimentación derivada antes del interruptor o procedente de una fuente independiente: se permite el cierre del interruptor sólo con el relé excitado (el bloqueo del cierre se efectúa mecánicamente).

(*B) El contacto S4 representado en la fig. 5 abre el circuito con el interruptor abierto y los vuelve a cerrar cuando se realiza un mando de cierre manual mediante el mando giratorio, según lo establecido en las normativas correspondientes a las máquinas herramienta (el cierre no se efectúa si el relé de mínima tensión no se encuentra alimentado).

Contactos auxiliares

SACE S1-S2

11 Dos contactos de intercambio para la señalización eléctrica de interruptor abierto o cerrado

12 Un contacto de intercambio para la señalización eléctrica de interruptor abierto o cerrado y un contacto de intercambio para la señalización eléctrica de interruptor abierto para la intervención de los relés termomagnéticos YO, YO1, YU (posición de disparo)

● = Número de figura del esquema
* = Véase la nota indicada por la letra
A1 = Aplicaciones del interruptor
A2 = Aplicaciones de mando a motor
A4 = Aparatos y conexiones indicativas para mando y señalización exteriores del interruptor
A11 = Unidad de diálogo tipo PR212/D, para la conexión con un sistema de gestión centralizada
A12 = Unidad de actuación tipo PR212/T, con relé auxiliares para la ejecución de los comandos procedentes de la unidad de diálogo
A12/KC = Mando de cierre de la unidad de actuación
A12/KO = Mando de apertura de la unidad de actuación
A13 = Unidad de señalización tipo PR212/K, con relé auxiliares para la señalización eléctrica de las funciones de protección con microprocesador de sobreintensidad
A14 = Unidad de alimentación
D = Retardador electrónico de mínima tensión (exterior al interruptor)
K51 = Relé con microprocesador de sobreintensidad tipo PR211 o PR212/P, con las siguientes funciones de protección:
- L contra sobrecarga con tiempo de intervención largo inverso
- S contra cortocircuito con tiempo de intervención corto inverso o independiente (disponible sólo con relé PR212/P)
- I contra cortocircuito con tiempo de intervención instantáneo
- G contra defecto a tierra con tiempo de intervención corto inverso (sólo disponible con relé PR212/P)

K51/Bus = Señalización eléctrica de alarma para defecto en la comunicación interior
K51/G = Señalización eléctrica de alarma para función de protección G en la zona de actuación
K51/I2 = Señalización eléctrica de alarma para función de protección I en la zona de actuación
K51/L = Señalización eléctrica de alarma para función de protección L en la zona de actuación
K51/pL = Señalización eléctrica de función de protección L en la zona de prealarma
K51/S = Señalización eléctrica de alarma para función de protección S en la zona de actuación
K51/YO1 = Señalización eléctrica de alarma para relé YO1 intervenido debido a sobreintensidad (Fig. 46-47) o incluso para 'trip test' (Fig. 41)
K87 = Relé diferencial tipo RC211 o RC212 (para interruptores S1-S2-S3)
KO = Para S3-S4-S5: relé auxiliar de apertura.
Para S6-S7: relé de apertura y carga de los resortes con contacto de cierre con posición mantenida, liberado por una palanca del mando a motor cuando el interruptor alcanza la posición de abierto y los resortes de cierre se han cargado
M = Para S3-S4-S5: motor con excitación en serie para la apertura y el cierre del interruptor.
Para S6-S7: motor para la apertura del interruptor y la carga de los resortes de cierre del interruptor
Q = Interruptor principal
Q/0 .. 2 = Contactos auxiliares del interruptor
R = Resistor exterior al interruptor suministrado para las tensiones de alimentación de los motores superiores a 220V
S1 = Para S3-S4-S5: contacto de posición accionado por una palanca del interruptor
Para S6-S7: contacto activado por la palanca del mando a motor: se cierra cuando el interruptor alcanza la posición de cerrado y se abre cuando el interruptor alcanza la posición de abierto (no conmuta cuando el interruptor llega a la posición de disparo)
S2 = Para S3-S4-S5: contacto de seguridad activado por:
- bloqueo a llave (si se encuentra presente)
- bloqueo por candados
- llave hexagonal de mando local.

Para S6-S7: contacto activado por la palanca del mando a motor: se abre cuando el motor alcanza la posición de cerrado y se cierra cuando el interruptor alcanza la posición de abierto (no conmuta cuando el interruptor llega a la posición de disparo). El contacto también se acciona mediante el dispositivo de bloqueo a llave (si se encuentra presente)
S3 = Contacto activado por la leva del mando a motor: se abre tras el cierre del contacto KO y se cierra cuando el interruptor alcanza la posición de abierto (no conmuta cuando el interruptor llega a la posición de disparo)
S4 = Contacto accionado por el mando giratorio del interruptor (véase nota B)
S75I/1..5 = Contactos para la señalización eléctrica de interruptor en posición de insertado (previsto sólo con interruptores en ejecución enchufable o extraíble (véase nota D)
S75S/1..5 = Contactos para la señalización eléctrica de interruptor en posición de removido y extraído (sólo previstos para interruptores con ejecución enchufable o extraíble (véase nota D)
SC = Pulsador o contacto para el cierre del interruptor. Para interruptores S3-S4-S5 el mando debe poseer una duración no inferior a 100 ms
SO = Pulsador o contacto para la apertura del interruptor
SO1, S02 = Pulsadores o contactos para la apertura del interruptor. Para interruptores S3-S4-S5 el mando tiene que poseer una duración superior a 100 ms (véase "Instrucciones para el restablecimiento del interruptor tras la intervención de los relés")
SY = Contacto para la señalización eléctrica de interruptor abierto para intervención de los relés termomagnéticos, YO, YO1, YU (posición de disparo)
TI = Transformador de corriente toroidal
TI/L1 = Transformador de corriente situado en la fase L1
TI/L2 = Transformador de corriente situado en la fase L2
TI/L3 = Transformador de corriente situado en la fase L3

Notas

TI/N = Transformador de corriente ubicado en el neutro
W1 = Interfaz serial con el sistema de control (interfaz EIA RS485)
X1, X2 = Conectores para los circuitos auxiliares del interruptor. Para interruptores S1-S2 sólo se suministran si se solicita.
X3, X4 = Conectores para los circuitos del relé con microprocesador de sobreintensidad (en el caso de interruptores en ejecución enchufable o extraíble, la extracción de los conectores se efectúa al mismo tiempo que la del interruptor)
X5, X6 = Placa de bornes de entrega de los circuitos del relé con microprocesador de sobreintensidad
XO = Conector para el solenoide de apertura YO1
XV = Placa de bornes de las aplicaciones
YC = Relé de cierre
YO = Relé de apertura
YO1 = Solenoide de apertura del relé diferencial tipo RC211 o RC212 (para S1-S2-S3) y del relé de sobreintensidad (para S4 .. S7)
YU = Relé de mínima tensión (véase nota B)

Instrucciones para el restablecimiento del interruptor tras la intervención de los relés

El interruptor se puede abrir no solamente con el mando a motor sino también mediante la intervención de los siguientes relés:
– sobreintensidad
– mínima tensión
– apertura
con la consiguiente apertura del contacto SY (si se encuentra previsto) en serie al relé KO.
En caso de disparo, para cerrar el interruptor hay que efectuar el restablecimiento mediante una apertura manual o eléctrica. Al terminar la operación, se vuelve a cerrar el contacto SY. La elección del tipo de restablecimiento depende de las exigencias del proyecto y de las condiciones de servicio. Se pueden sugerir las siguientes hipótesis:

1) Restablecimiento exclusivamente manual

El mando eléctrico de apertura (contacto SO1) tiene que conectarse en serie al contacto SY. La apertura (para S3-S4-S5 realizada mediante el relé auxiliar KO) no es posible hasta que el interruptor se encuentra en la posición de disparado. Para restablecer el interruptor hay que accionar la correspondiente palanca hasta que el interruptor pasa a la posición de abierto y los resortes de cierre se cargan completamente.

2) Restablecimiento eléctrico con intervención del operador

El mando eléctrico de apertura normal (contacto SO1) tiene que conectarse en serie al contacto SY.
Se ha previsto otro mando de apertura (contacto SO2), conectado directamente en serie al relé KO para S3-S4-S5 o conectado directamente al polo A3 del conector X2 para S6-S7, que tiene que estar controlado, por ejemplo con un pulsador de llave, y que pueda utilizarse solamente si la información recibida por el responsable del puesto de control permite excluir que el disparo sea debido a un cortocircuito o bien las causas del mismo han sido eliminadas

3) Restablecimiento eléctrico permitido siempre

El mando eléctrico de apertura (contacto SO2) está conectado directamente en serie al relé KO para S3-S4-S5 o está conectado directamente al polo A3 del conector X2 (para S6-S7) y, por lo tanto, siempre está permitido.
Ejemplo de empleo: restablecimiento automático del interruptor inmediatamente después de la intervención de los relés.
N.B. Si se encuentra presente el relé de sobreintensidad, es necesario identificar las causas que han provocado el disparo del interruptor para evitar un nuevo cierre en condiciones de cortocircuito.

En todos los casos, siempre es posible efectuar el restablecimiento manual.

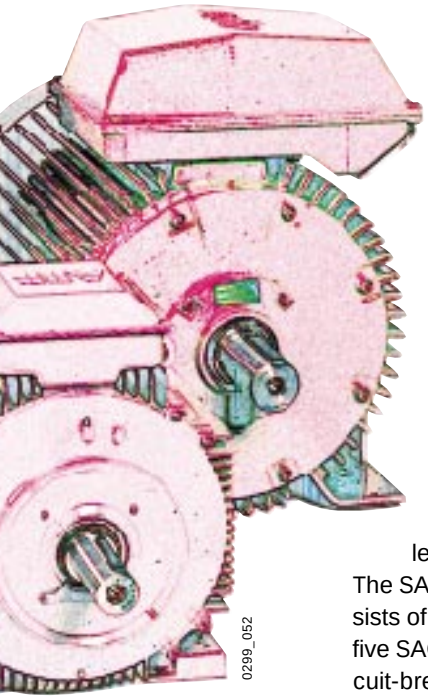
SACE Isomax S Motor Protection. The protection functions are completed



Modern and rational solutions for motor protection

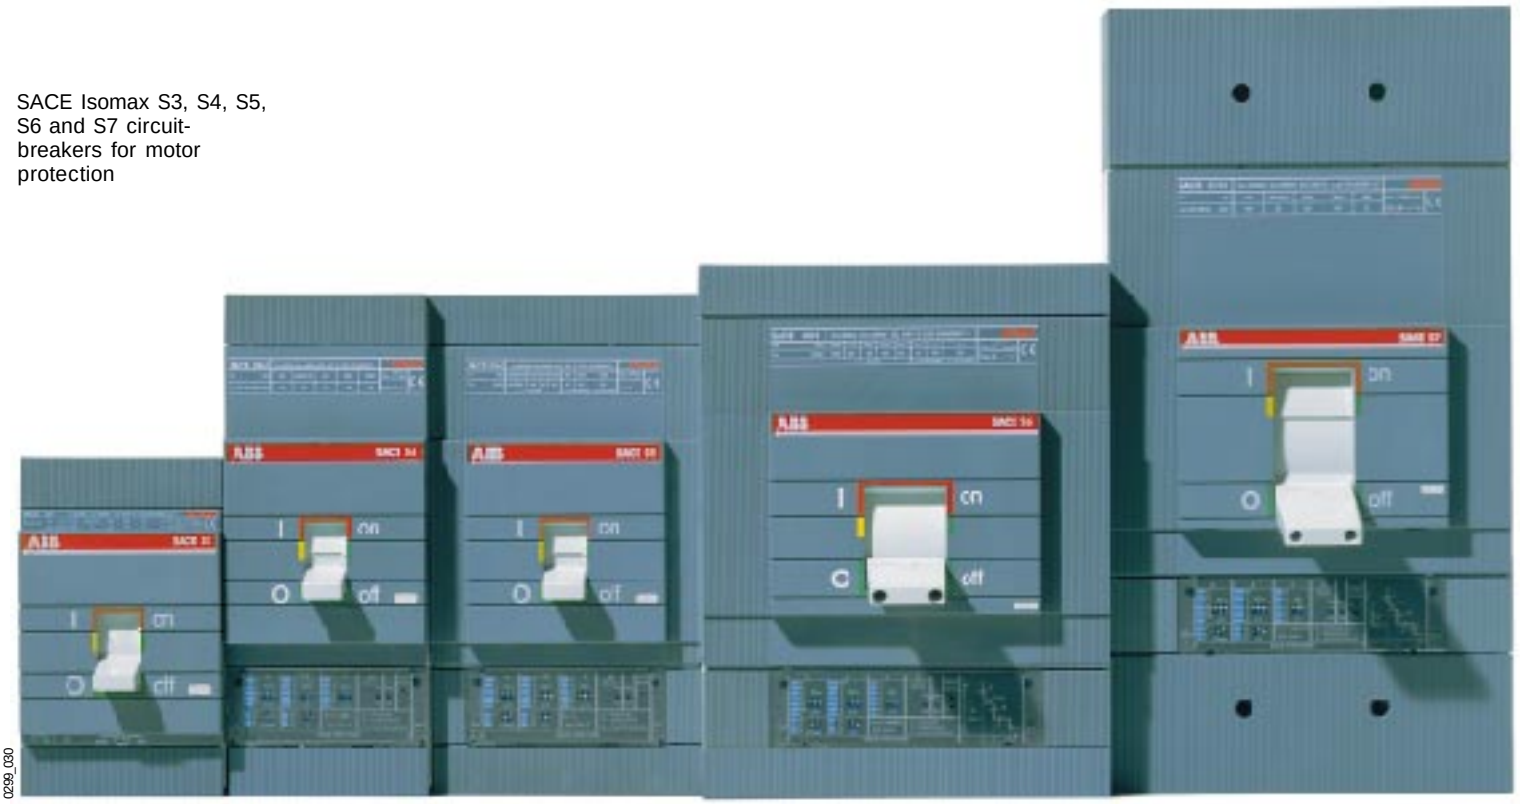
Within the sphere of SACE Isomax S low voltage moulded-case circuit-breakers, there is a range which stands out and fulfils the technical requirements regarding motor starting and protection in particular.
The result of the most advanced research in the field of electrical installation control, the range of SACE Isomax S “Motor Protection” circuit-breakers offers high performances with particularly limited overall dimensions, flexibility, practical usage and simple installation, all combined with an extremely high level of technology.
The SACE Isomax S series for motor protection consists of eight models:
five SACE S3N-H, S4N-H, S5N-H, S6N-H, S7S-H circuit-breakers, with rated currents from 3 A to 1000 A and breaking capacities from 35 to 65 kA (at 380/415 V a.c.) and three SACE S3X, S4X and S6X current-limiting circuit-breakers, with rated currents from 3 A to 630 A and breaking capacity from 200 kA (at 380/415 V a.c.).

Selection of a circuit-breaker suitable for motor protection is fundamental in adding value to the functionality and efficiency of the motor: just think of the increased useful life of a well-protected motor, of the easy and rapid resetting following a trip, of the lower costs due to machine stoppage and of the almost total safety level of the operating personnel.

From classic motor protection to electronic microprocessor-based protection

SACE Isomax S3N-H 160/250 circuit-breakers and the relative S3X 125/200 current-limiting circuit-breakers are fitted with an instantaneous adjustable

SACE Isomax S3, S4, S5, S6 and S7 circuit-breakers for motor protection



0299_017

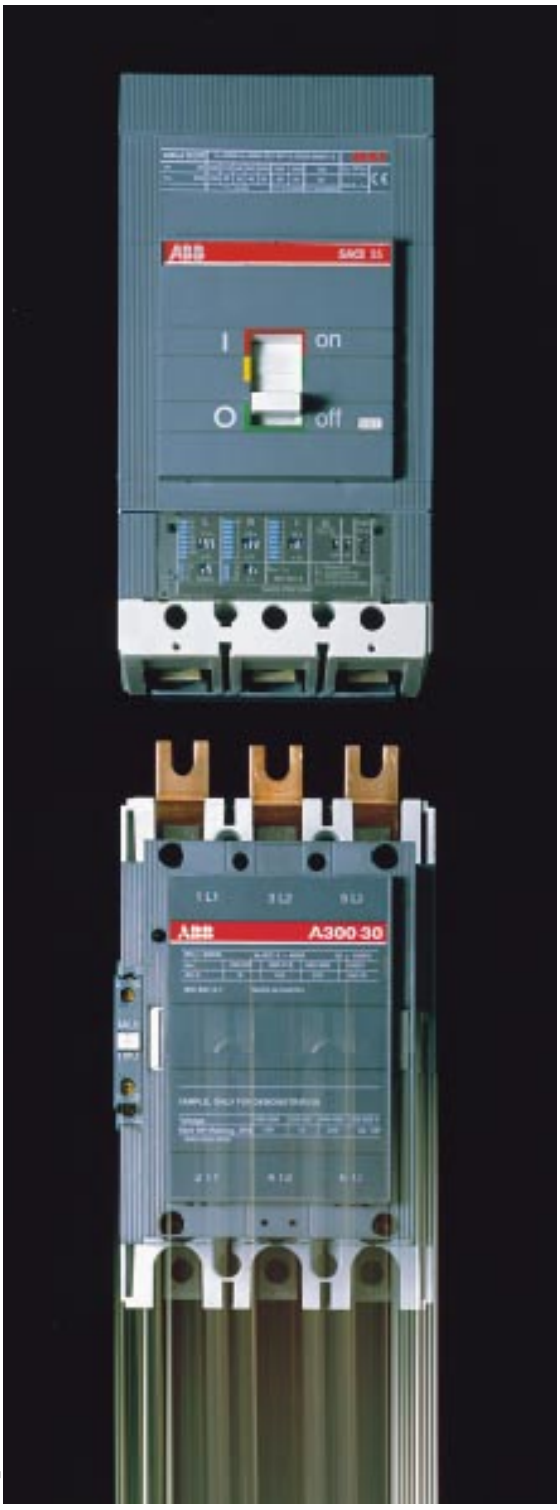
magnetic only release which, used in combination with a thermal relay and with a contactor, ensures motor switching and protection in the traditional way. SACE Isomax S4N-H 160/250, S5N-H 400, S6N-H 800, S7H 1250 circuit-breakers and the relative current-limiting S4X 250 and S6X 400/630 circuit-breakers ensure motor protection by means of the SACE PR212/MP electronic release (ABB SACE L.V. International Patent), which activates protection against overload, against rotor blockage, against short-circuit and against missing and/or unbalanced phase. The circuit-breakers are used in combination with a contactor for motor switching. The calculation algorithms conditioning their operation are memorised in the release microprocessors, checked in the ABB SACE L.V. laboratories. The principle is based on measurement of the effective current value according to sampling criteria, reconstruction and measurement of the signal, appropriate for the different fault conditions which can occur.

0299_029

SACE Isomax S6X, S4X and S3X current-limiting circuit-breakers for motor protection

Coordinated solutions with the ABB system

The range of SACE Isomax S moulded-case circuit-breakers for motor protection is perfectly co-ordinated with the new line of ABB contactors. The latter, defined as A-Line, together with the line of overload thermal relays and SACE Isomax S moulded-case circuit-breakers, are the basis for the new generation of pieces of apparatus specially designed to ensure a system of products which can be integrated according to the required applications. All this not only has the aim of continuously improving its products, but above all of providing design engineers, installers and end users with the best solutions in terms of performance and reliability combined with simplicity of the system.



0299_049

Apart from the classic circuit-breaker-contactor-thermal relay combination, the SACE Isomax S circuit-breakers for motor protection, starting from model S4, are combined with just the contactor (example of composition between S5H and PR212/MP and series A300-30 contactor)

In particular, the SACE Isomax S circuit-breakers and the “A” series contactors provide a very special solution with regard to compactness, having the same width and design characteristics, thereby saving space, assembly material, installation time and relative cabling.
The circuit-breaker-contactor group enhances this feature even further with the SACE PR212/MP electronic overcurrent release which, inside the SACE Isomax S circuit-breakers, allows an extremely compact protected starter to be constructed, implementing the overload protection in compliance with IEC Standard 947-4-1.

0299_047

SACE Isomax S moulded-case circuit-breakers and the new A series contactors share the same width and depth and have been designed to make up a single compact unit

Compliance with Standards. Approvals

Safety recognised internationally and protection of the environment

The SACE Isomax S circuit-breakers for motor protection with electronic microprocessor-based releases comply with the IEC 947-1, IEC 947-2, IEC 947-4-1, IEC 1000, EN 55081 and EN 55082 International Standards.

The ABB SACE Quality System complies with the International ISO 9001 Standard and to the equivalent EN ISO 9001 European Standards and the UNI EN ISO 9001 Italian Standards. The certifying Organisation is the Italian Shipping Register (RINA- QUACER). ABB SACE has obtained its third re-confirmation of qualification.

The ABB SACE L.V. Test Room is accredited by SINAL. The apparatus complies with the prescriptions for on-board installations and is approved by major Shipping Registers, such as LLOYD'S REGISTER OF SHIPPING, GERMANISCHER LLOYD, BUREAU VERITAS, RINA, and DET NORSKE VERITAS.

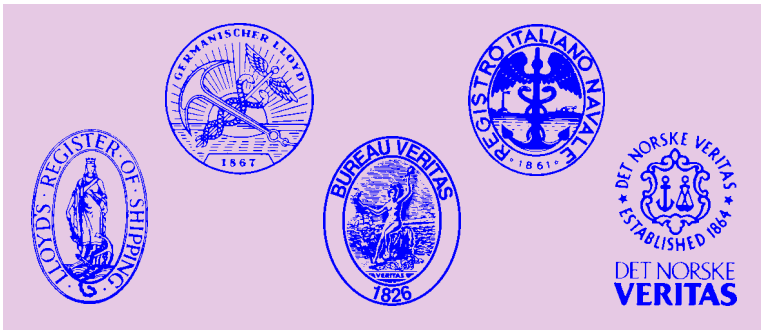
The attention paid to protecting the environment is another important priority for ABB SACE, and, thanks to the use of new production systems carried out with an eye to ecology, this has allowed a reduction of more than 20% in raw materials and processing waste during construction of the circuit-breakers.

CSIS9099

CSIS9098

Selection of materials, processes and packaging has been made by optimising the real environmental impact of the product and by using recyclable materials.

The prizes obtained by ABB SACE L.V. at the Forum Design in Hannover and at Electtro in Paris bear testimony to the attention which has always been given to man and respect for ergonomic criteria.



INDUSTRIE FORUM DESIGN HANNOVER

The SACE Isomax S series has been studied respecting the most advanced ergonomic criteria: this is testified by the prize awarded with the IF seal to the circuit-breakers at the Forum Design in Hannover 1997.

Overcurrent releases

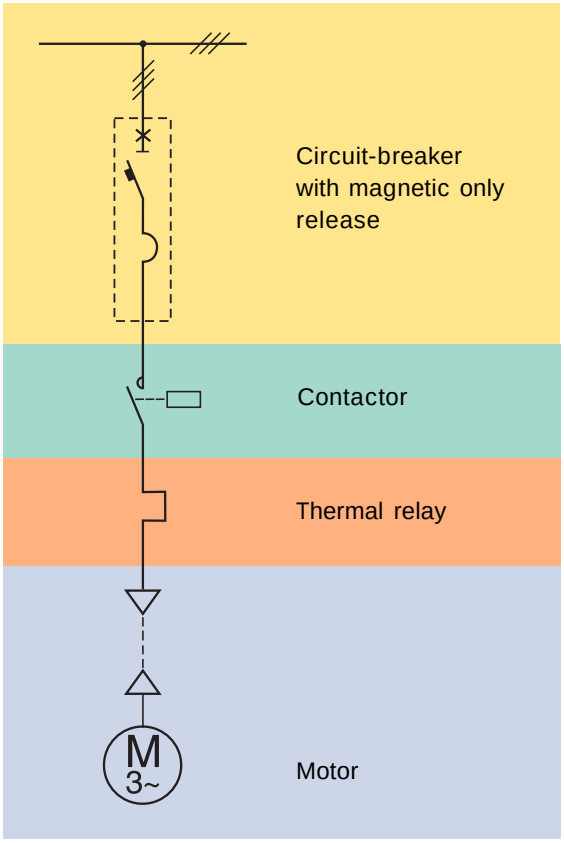
Magnetic only overcurrent releases

The SACE Isomax S3N-H 160/250 and S3X 125/200 circuit-breakers are fitted with magnetic only adjustable releases for protection against short-circuit. These circuit-breakers must be used in combination with a thermal relay (for protection against overload and against missing or unbalanced phase) and with a contactor, to form a device for motor switching and protection.

The circuit-breaker-thermal relay-contactor group takes the name of protected starter.

The circuit-breaker can be used for a range of release setting currents from 3 A to 200 A according to the table shown below.

The magnetic trip current is adjustable with a variable parametrisation range - continuous - from 4 to 12 times the rated In setting current.



Magnetic only adjustable overcurrent releases

Circuit-breaker					Phases L1 - L2 - L3	
S3N 160	S3H 160	S3N 250 S3H 250	S3X 125	S3X 200	Setting [A]	Magnetic adjustment [A] Im = 4 ... 12 x Ith

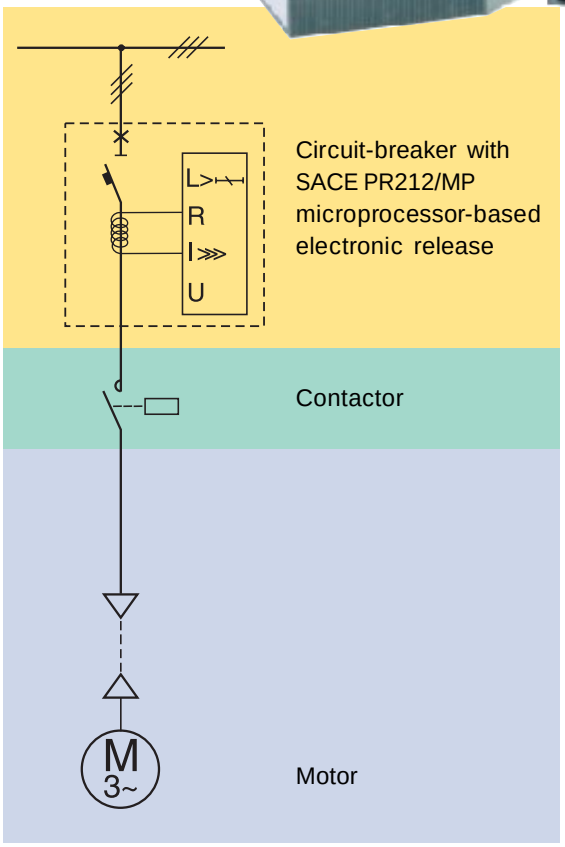
SACE PR212/MP microprocessor-based electronic releases

SACE Isomax S4N-H 160/250, S5N-H 400, S6N-H 800, S7S-H 1250 and S4X 250 and S6X 400/630 circuit-breakers are fitted with SACE PR212/MP electronic releases constructed using microprocessor-based electronic technology. This allows functions which ensure high trip precision, extreme reliability and insensitivity to variations in external temperature to be obtained. The SACE Isomax S circuit-breaker fitted with the PR212/MP release (complying with the IEC 947-4-1 International Standards regarding motor protection), is used together with a contactor for switching the motor. The microprocessor-based electronic releases are self-supplied and consist of three current transformers, the SACE PR212/MP protection unit and an opening solenoid which acts directly on the operating mechanism group of the circuit-breaker. The current transformers, housed inside the release unit, provide the energy and signal required for correct operation of the protection.
The release is temperature-compensated and is sensitive to the lack of phase according to Table IV of the 947-4-1 7.2.1.5.2 Standard.



SACE PR212/MP microprocessor-based electronic overcurrent releases for motor protection

L = Protection function against overload with relative setting current (**I1** = 0,5-0.6-0.7-0.8-0.85-0.9-0.95-1 x In - **Class** = 10A, 10, 20, 30)
R = Protection function against rotor block with relative current and setting time (**I5** = 3-4-5-6-7-8-10 x I1 - **t5** = 1-4-7-10 s)
I = Protection function against short-circuit with relative setting current (**I3** = 6-7-8-9-10-11-12-13 x In)
U = Protection function against phase loss or unbalance of a phase with relative current and setting time (**Iu** = 0.4 x I1 - **t** = 4 s)

Basic version and conversion kits

SACE Isomax S circuit-breakers for motor protection are always supplied in the three-pole fixed version with front terminals (basic version).
By means of additional kits, other versions with different types of terminals, summarised in the table below, can be constructed.
Still by means of special conversion kits, the plug-in and withdrawable versions of the circuit-breakers can be constructed.

For different types of terminals and versions, application of the terminal covers which are part of the standard circuit-breaker supply is foreseen. In particular, the moving parts of plug-in or withdrawable circuit-breakers are always complete with terminal covers.
For the version with front terminals, the terminal covers are supplied with separation partitions between the phases.

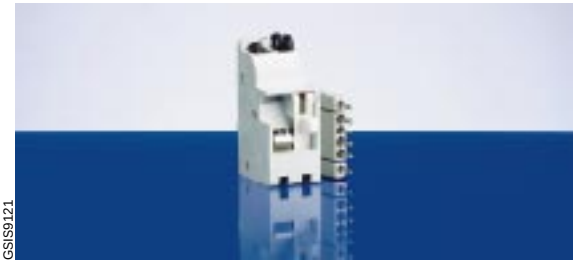
Accessories

The completeness of the range and the possibility of adding accessories to the circuit-breakers for motor protection is ensured by a wide range of accessories to satisfy all requirements.
Below, some of the main accessories which characterise the SACE Isomax S series are listed.
For further information, please consult the SACE Isomax S technical catalogue, code 649240.



GSIS9121

Auxiliary contacts

These carry out electrical signalling of the state of operation of the circuit-breaker: Open - Closed - Release trip.

GSIS9045

Shunt opening release

This allows circuit-breaker opening by means of an electric control. Operation is ensured for an auxiliary power supply voltage between 70% and 110% of the rated voltage value of the power supply Un, both in a.c. and in d.c.

GSIS9052

Motor operator

With direct action (for S3, S4 and S5 circuit-breakers) and with stored energy (for S6 and S7 circuit-breakers).
The opening, closing and resetting commands are operated by the motor which acts directly on the circuit-breaker lever.

GSIS9047

Instantaneous or time-delayed undervoltage release

This opens the circuit-breaker when the power supply voltage to the release is missing, or for drops to minimum values of 0.7 x Un with a trip range of 0.7 to 0.35 x Un.
The undervoltage release can be combined with a time-delay device with external electronic power supply which allows circuit-breaker opening to be delayed in the case of a drop in or missing voltage of the release power supply itself, according to fixed delays of 0.5 - 1 - 2 - 3 s, so as to prevent unwarranted trips caused by temporary malfunctions.

GSIS9055

Rotary handle operating mechanism

This is used to facilitate circuit-breaker operation thanks to its ergonomic handle. It is always fitted with a padlock in the open position, which prevents closure of the circuit-breaker. The lock hole can take up to 3 padlocks (not supplied) with a stem diameter of 6 mm.

CSIS9057

Key lock

Different versions with different keys for each circuit-breaker or with the same keys for groups of circuit-breakers are available.

PSIS9646

Insulating terminal covers

To prevent accidental contact with live parts, bottom terminal covers (for all the circuit-breakers, with IP30 degree of protection) and top terminal covers (for all the circuit-breakers, with IP40 degree of protection) are available. The degrees of protection indicated are valid for circuit-breakers installed in switch-boards. To prevent their removal, screws which can be sealed with lead can be supplied.

PSEM9070

SACE TT1 test unit

This is a pocket unit which allows checking of the SACE PR212/MP electronic release trip for S4-S5-S6 and S7 circuit-breakers. The positive outcome of the test makes the circuit-breaker open.

Construction characteristics

Construction characteristics

The SACE Isomax S series for motor protection has been designed with features which allow all those who operate on the circuit-breakers (installers, operators and maintenance personnel) to work in complete safety thanks to some special characteristics, such as:

– double insulation, with increased safety in managing and inspecting installations
– positive operation, which ensures safe and reliable visual signals
– easy inspection, with reduction of maintenance times
– electromagnetic compatibility, in compliance with the IEC 947-2 Annex F International Standards
– resistance to vibrations of mechanical type or due to electromagnetic effect, in compliance with the IEC 68-2-6 International Standards and to the strict regulations of the most important classification Organisations and Shipping Registers
– assembly in different installation positions without variation in the rated characteristics
– operation possible with ambient temperatures between -25 °C and + 70°C
– installation at altitudes up to 2000 m without alterations to the rated performances

Protection functions and parametrisations of the SACE PR212/MP release

Function L
Protection against overload

Function L protects the motor against undesired overloads according to the indications and classes defined in the IEC 947-4-1 Standards.
The protection is based on a pre-defined thermal model (ABB SACE L.V. International Patent) which, by simulating overtemperatures of copper and iron inside the motor, allows precise safeguarding of the machine.
The protection intervenes when the preset overtemperature is reached.
The trip time is fixed by selecting the trip class defined by the above-mentioned Standards.
The function is temperature-compensated and sensitive to the missing/unbalanced phase according to the IEC 947-4-1 Standard.

Parametrisation of protection L

I1 = 0.5 - 0.6 - 0.7 - 0.8 - 0.85 - 0.9 - 0.95 - 1 x In
where I1 is the rated service current of the circuit-breaker which must be the same or higher than that of the motor to be protected (I1 ≥ Ie) and In is the rated current of the current transformers.
t1 = 4 - 8 - 16 - 24 s
where t1 is the trip at 7.2 x I1 cold

Class 10A - 10 - 20 - 30
are the motor starting classes which determine the trip times for overload according to the IEC 947-4-1 4.7.3 Standards Table II.

Tolerances: according to IEC 947-4-1 Standard.

Function R
Protection against rotor block

The R function protects the motor against any rotor blockage during operation.
This protection is automatically disabled for the whole motor starting phase and is then re-activated.
The protection protects right from low current increases (from 3 times the I1 circuit-breaker service current) and can also be disabled.
Both the current level to be tripped as well as the delay in tripping can be selected.
The protection intervenes when at least one of the phase currents exceeds the preset value and remains above that threshold for the t5 time set.

Parametrisation of protection R

I5 = OFF - 3 - 4 - 5 - 6 - 7- 8 - 10 x I1
where I5 is the current at which the rotor is considered to be blocked and I1 is the rated service current of the circuit-breaker selected for function L.

t5 = 1 - 4 - 7 - 10 s
where t5 is the preset time threshold above which the release trips.

Tolerances: ± 10% (tripping threshold tolerances)
± 20% (trip time tolerances)

Function I
Protection against short-circuit

This protection function intervenes in the case of a short-circuit between phase and phase. It is sufficient for a single phase to exceed the threshold set to cause immediate opening of the circuit-breaker (the protection cannot be excluded).
The trip current can be adjusted up to 13 times the rated current of the release, whereas the time is fixed.
To prevent unwarranted trips during starting, the protection recognises whether the motor to be protected is in the starting phase or whether there is a short-circuit.
This is to allow starting under completely safe conditions.

Parametrisation of protection I

I3 = 6 - 7 - 8 - 9 - 10 - 11 - 12 - 13 x In
where I3 is the instantaneous trip current for short-circuit and In is the rated current of the current transformers.

To prevent unwarrented trips during the motor inrush phase, instantaneous tripping of protection I takes place at 1.5 x I3 (for I3 ≤ 9 x In), whereas for higher values (I3 > 9 x In), tripping takes place at 13.5 x In.

Tolerances: ± 20% (tripping threshold tolerances)
± 20% (trip time tolerances)

Function U

Protection against loss and/or unbalance of a phase

Function U can be used in those cases where particularly precise control is needed regarding loss and/or unbalance phase currents. This function can be excluded and intervenes if the effective value of one or two currents drops below the level of 0.4 of the current I1 set with function L and remains there for more than 4 seconds.

Parametrisation of protection U

On, (with I6 = 0.4 x I1 and t6 = 4 s).

Off, in the off position, the release remains sensitive to the loss of phase according to the IEC 947-4-1 Standard, modifying the trip curve for protection L.

Tolerances: ± 20% (tripping threshold tolerances)
± 20% (trip time tolerances)

Selection of the release parametrisation method

By means of the microswitch located on the front, the release can be fitted for parametrisation:

- **Man.** (manual), thresholds and times are adjusted by using the microswitches on the front of the release
- **Elt.** (electronic), stored in a non-volatile memory and predefined by ABB SACE L.V.

Protection L
against motor overload

Protection R
against blocked rotor

Protection I
against instantaneous short-circuit

Protection U
against loss and/or unbalanced phase

Characteristics of the SACE PR212/MP microprocessor-based electronic release

Overloading capacity	**2 x In continuously, 7,2 x In for 35 s at 45 °C**
Operating temperature	**– 25 °C ... + 70 °C**
Maximum percentage of relative humidity	**90%**
Rated operating frequency	**45 - 66 Hz, able to measure harmonics up to 550 Hz**
Current measurement method	**true effective value up to 3 x In (functions L, R, U)**
	peak value for values higher than 3 x In (functions L, R, U)
	peak value for function I
Electromagnetic compatibility	**in compliance with Standard: IEC 947-2 Annex F**
Electrostatic discharges	**in compliance with Standard: IEC 1000-4-2**
Radiated electromagnetic field	**in compliance with Standard: IEC 1000-4-3**
Short-time transients	**in compliance with Standard: IEC 1000-4-4**
Mean Time Between Failure (MTBF)	**15 years (at 45 °C)**

Note

For the current-limiting and specific let-through energy curves of SACE S3, S4, S5, S6 and S7 circuit-breakers for motor protection, please refer to what is indicated in the catalogue on SACE Isomax S "Low voltage moulded-case circuit-breakers" (code 649240) and in the Annex "Low voltage current-limiting circuit-breakers" (code 649294), for the corresponding types of circuit-breakers.

Trip curves of circuit-breakers with SACE PR212/MP electronic release

Use of the trip curves of circuit-breakers with SACE PR212/MP electronic release

For correct parameter setting of the SACE PR212/MP electronic release, it may be useful to compare the overall circuit-breaker curve with the motor starting curve.
For this purpose, with the protection function graphics shown on the following pages, it is possible to draw the overall curve required for the circuit-breaker fitted with SACE PR212/MP release simply and immediately.

N.B. For function L, as for all the other functions, make sure you place a glossy tracing sheet over the curve so that the times on the axis of the co-ordinates coincide.

- **Function L (cannot be excluded) - Protection against overload**

  To protect the motor against any overloads, as a first step it is necessary to adjust function L to a current **I1** higher than or equal to the rated current of the motor Ie: **I1 ≥ Ie**.
  For example, if Ie = 135 A, an S4H160 circuit-breaker can be selected with In = 160 A and the following adjustment carried out: I1 = 0.85 x In = 136 A.
  The second step is to select the trip class according to the motor starting time **ta**. For a motor with a start-up overload of 6 seconds, class 10 can be selected, with a trip time of 8s at 7.2 x I1.
  To trace the curve correctly on the glossy sheet, according to **I/In**, simply place the glossy sheet over the graph of function L so that I/In = 0.85 (on the glossy sheet) corresponds to I/I1 = 1 (on the graph) and draw the curve relative to class 10.

- **Function R (can be excluded) - Protection against rotor blockage**

  Protection against rotor blockage can be set both with regard to the trip current **I5** = 3 ... 10xI1 (in this case I5 = 3 ... 10 x 0.85 x 160), and with regard to the trip time **t5**.
  To trace the curve correctly on the glossy sheet, simply place the glossy sheet over the graph of function R so that I/In = I1/In (on the glossy sheet) corresponds to I/I1 = 1 (on the graph). In this case I/In = I1/In = 0.85, and draw the desired curve.

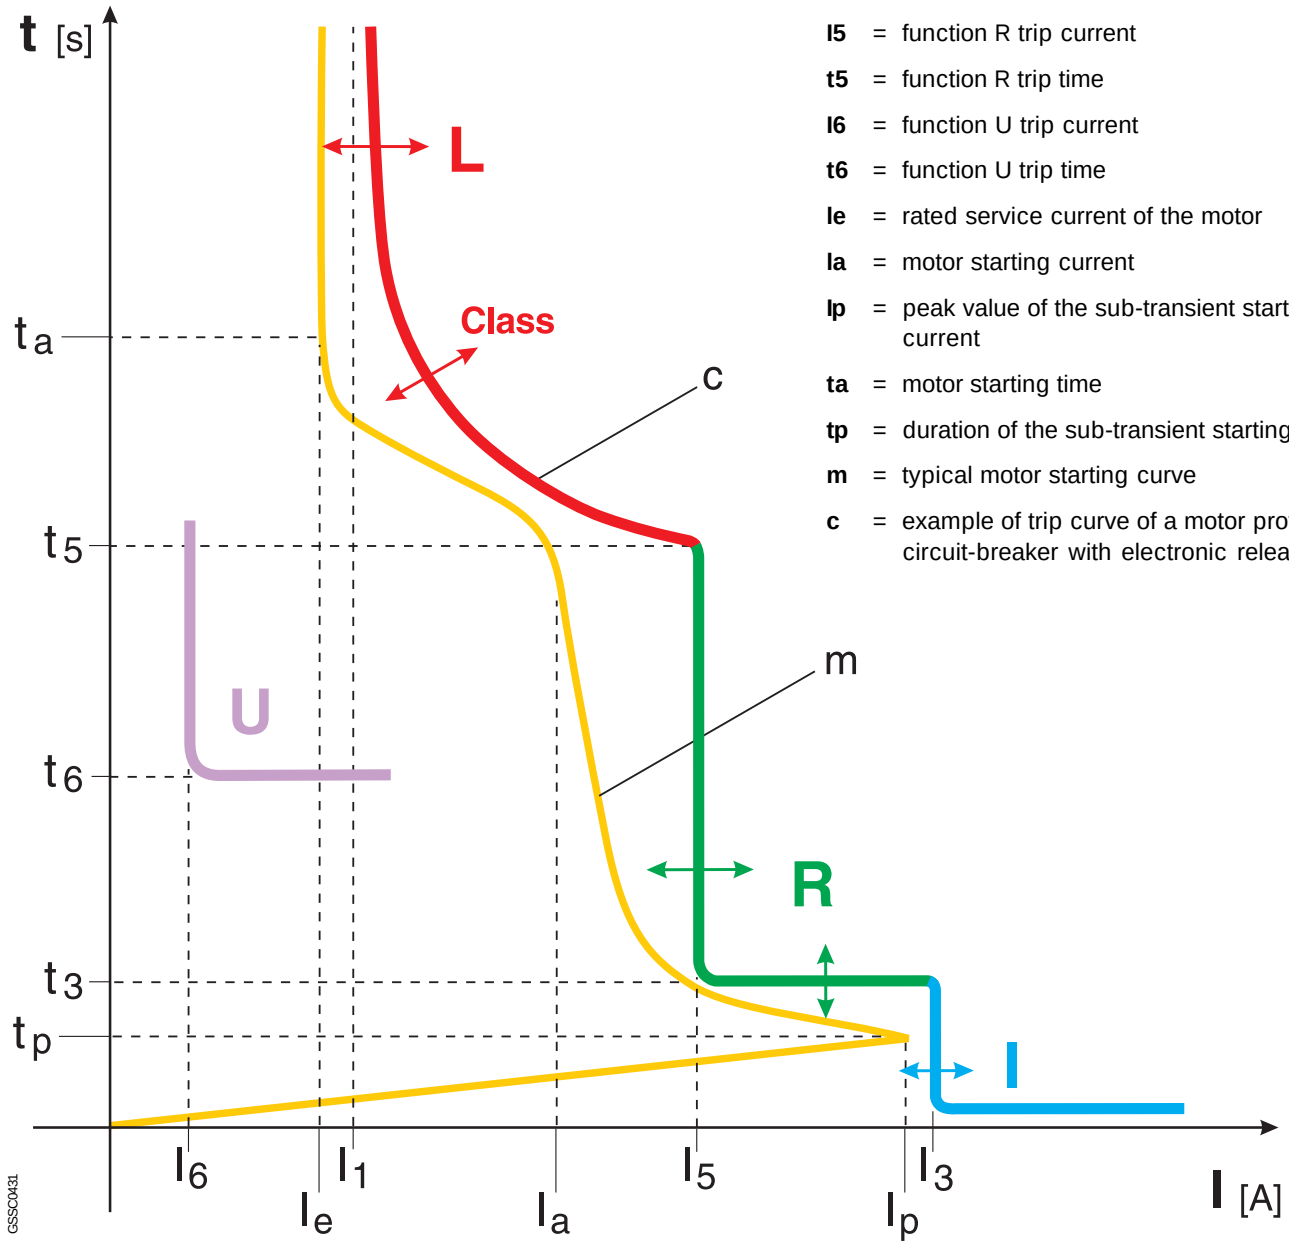
- **Function I (cannot be excluded) - Protection against short-circuit**

  This protection function against short-circuit recognises whether the motor is in the starting phase, thereby avoiding unwarranted trips; the trip threshold can be set from 6 x In to 13 x In.
  To trace the curve correctly on the glossy sheet, simply place the glossy sheet over the graph of function I so that I/In = 1 (on the glossy sheet) corresponds to I/In = 1 (on the graph) and draw the desired curve.

- **Function U (can be excluded) - Protection against loss and/or unbalance of a phase**

  Protection against loss or unbalance of a phase, if set to ON, intervenes when one or two phases have a current lower than 0.4xI1 (0.4 x 0.85 x In = 0.4 x 0.85 x 160 A = 54.4 A in this case).
  To trace the curve correctly on the glossy sheet, simply place the glossy sheet over the graph of function U so that I/In = I1/In (on the glossy sheet) corresponds to I/I1 = 1 (on the graph). In this case I/In = I1/In = 0.85, and draw the desired curve.

Typical operating characteristic of an asynchronous motor



I1 = function L trip current
I3 = function I trip current
I5 = function R trip current
t5 = function R trip time
I6 = function U trip current
t6 = function U trip time
Ie = rated service current of the motor
Ia = motor starting current
Ip = peak value of the sub-transient starting current
ta = motor starting time
tp = duration of the sub-transient starting phase
m = typical motor starting curve

Circuit-breaker applications

Protection, starting and switching of three-phase asynchronous motors

Three-phase asynchronous motors, for low and high powers, are widely used in all sectors. Starting, switching and protection are fundamental operations for correct use of the motor.

The traditional system used for this purpose foresees three different devices: a circuit-breaker for protection against short-circuit, a thermal relay for protection against overload and a contactor for switching. Everything must necessarily take into account the problems which arise during starting.

Naturally, different factors must be taken into consideration in selecting these devices, such as:

– the power of the motor
– the starting diagram: direct, with gear inversion, star-delta, with reactances, or with static feeder
– the type of motor: with cage rotor or with wound rotor
– the fault current at the point of the network where the motor is installed.

The SACE S3H 160 circuit-breaker fitted with an adjustable magnetic only release fulfils these requirements in the most classic way, since it is used combined with a thermal relay for protection against overload and missing phase and a contactor for switching.

ABB SACE has constructed the SACE PR212/MP electronic microprocessor-based release which integrates the protection functions against short-circuit and overload in a single product, thanks to the precision and reliability of its electronics.

Other specific functions for motor protection, such as protection against rotor blockage and against missing and unbalanced phase, are built into the product itself, which is therefore a compact, reliable and complete protection system.

The table shows three different starter diagrams and, for each of these, the functions carried out by the various devices.

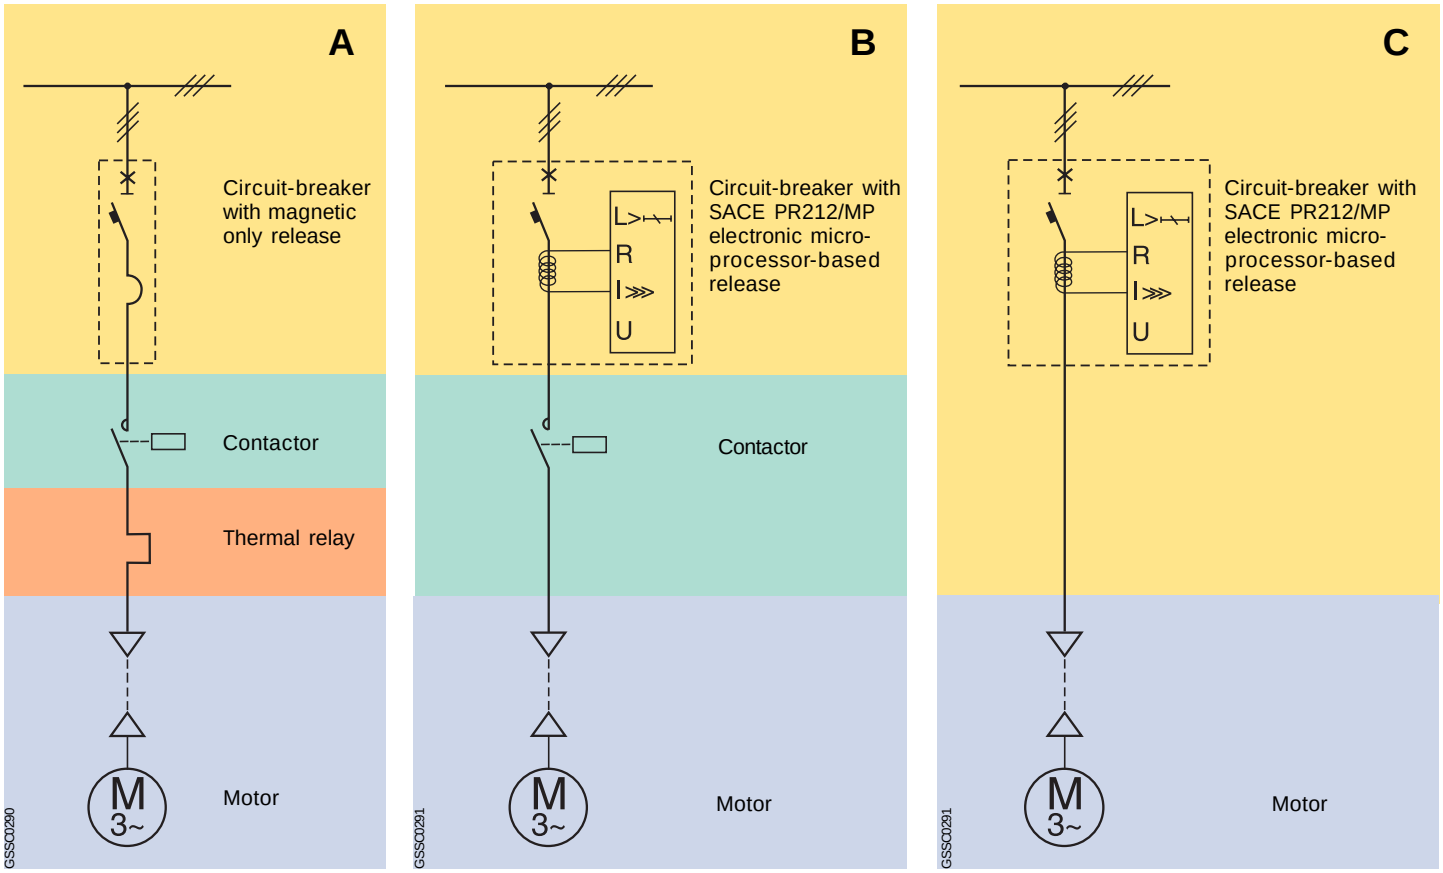
Standards

The International Standard regarding motor protection is the IEC 947-4 Standard.
This foresees trip fields within which a device must intervene to ensure maximum safety during starting and use of the motor.

The Standard defines 4 Classes of intervention which define the starting time of the motor.
The SACE PR212/MP release allows selection of the most suitable class according to the trip times shown in the table, thereby obtaining 4 levels of co-ordination: from normal starting to heavy starting.

Class	Trip according to IEC 947-4-1 Standards				PR212/MP trip
compensated relay (*)	1.05 x I1	1.2 x I1	1.5 x I1	7.2 x I1	at 7.2 x I1
10A	> 2 hours	< 2 hours	< 120 s	2 ... 10 s	4 s
10	> 2 hours	< 2 hours	< 240 s	4 ... 10 s	8 s
20	> 2 hours	< 2 hours	< 480 s	6 ... 20 s	16 s
30	> 2 hours	< 2 hours	< 720 s	9 ... 30 s	24 s

(*) Trip at 1.0 x I1 for uncompensated thermal relay



Coordination tables according to IEC 947-4-1 Standards

ABB SACE L.V. proposes a complete range of co-ordination tables to facilitate selection of SACE Isomax S circuit-breakers in relation to the co-ordination requirements with the other devices of the starter (in compliance with the IEC 947-4-1 Standards).
Each table is defined on the basis of an ambient temperature of 40°C. For higher ambient temperatures, a reduction factor of the following components must be applied:

- *For moulded-case circuit-breakers, 0.85 x In when the ambient temperature is 60°C*
- *For thermal overload relays, 0.9 when the ambient temperature is 70°C. There is no reduction factor up to 55°C.*

To facilitate reading, the following parameters are also indicated:

- ***Ie**, rated motor current*
- ***Pn**, rated motor power*
- ***In**, rated circuit-breaker current*
- ***I1**, adjustment current of the protection against overload*
- ***I3**, adjustment current of the protection against short-circuit*
- ***Imax**, maximum testing current, of the protected starter, foreseen by the standard.*

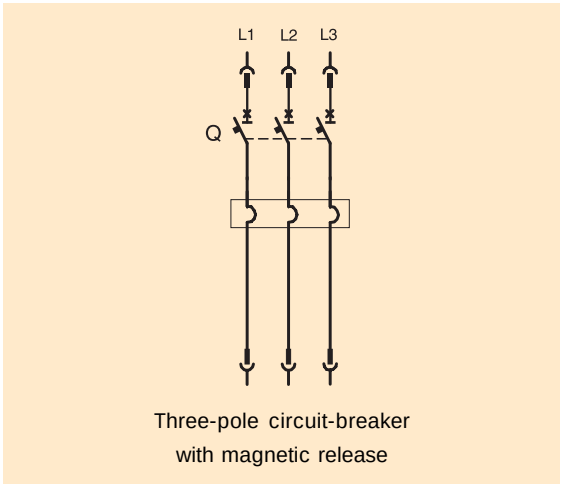
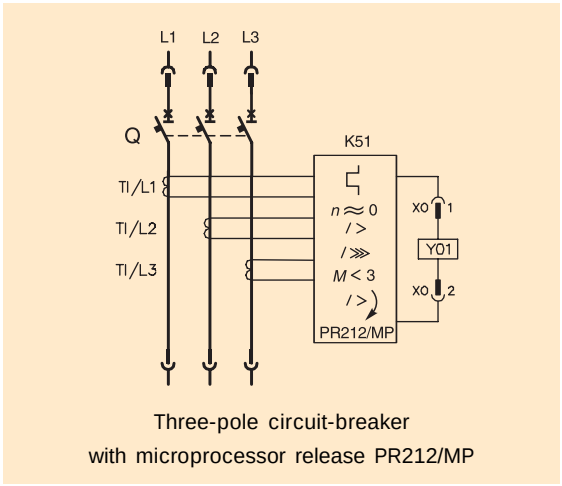
Circuit diagrams.
Operating status shown

The circuit is shown in open and fixed version circuit-breaker.



GSSC0428

Three-pole circuit-breaker
with magnetic release



GSSC0429

Three-pole circuit-breaker
with microprocessor release PR212/MP

Graphic symbols (Standards IEC 617 and CEI 3-14 … 3-26)

Thermal effect	Current transformer	Locked-rotor detection relay operating by current sensing
Electromagnetic effect	Circuit-breaker-disconnector with automatic release	Phase-failure detection relay in a three-phase system
Mechanical connection (link)	Operating device (general symbol)	Instantaneous overcurrent or rate-of-rise relay
Plug and socket (male and female)	Thermal relay	Phase-balance current relay

Key

K51 = PR212/MP microprocessor-based overcurrent release with the following protection functions:
- L against overload (thermal protection)
- R against rotor block
- I against short-circuit
- U against phase loss or unbalance of a phase

Q = Main switch
TI/L1 = Current transformer located on phase L1
TI/L2 = Current transformer located on phase L2
TI/L3 = Current transformer located on phase L3
XO = Connector for the opening solenoid YO1
YO1 = Opening solenoid for the overcurrent release

(*) Notes for current-limiting circuit-breakers

– The contact isolators on the fixed parts of S3-S4 circuit-breakers (plug-in and withdrawable versions) have been modified (during 1997) to make them suitable for the moving parts of S3X-S4X current-limiting circuit-breakers.
The "new" contact isolators are supplied in the conversion kit for S3X-S4X models (used for converting them into moving parts). The operation is simple to perform and can be carried out by the user with the help of the instructions supplied. It enables one to maintain the compatibility of S3X-S4X models and S3-S4 fixed parts that are already stored in the warehouse or installed.
The modification is not required on S3X or S4X current-limiting circuit-breakers that are supplied complete with fixed parts or on fixed parts purchased after February 1998.
The contact isolators can be supplied as spare parts if required.

– The existing fixed parts for S3-S4 circuit-breakers are not compatible with current-limiting apparatus if they are fitted with front terminals for copper cables FC Cu.

SACE Isomax S
La serie más importante de interruptores en caja moldeada

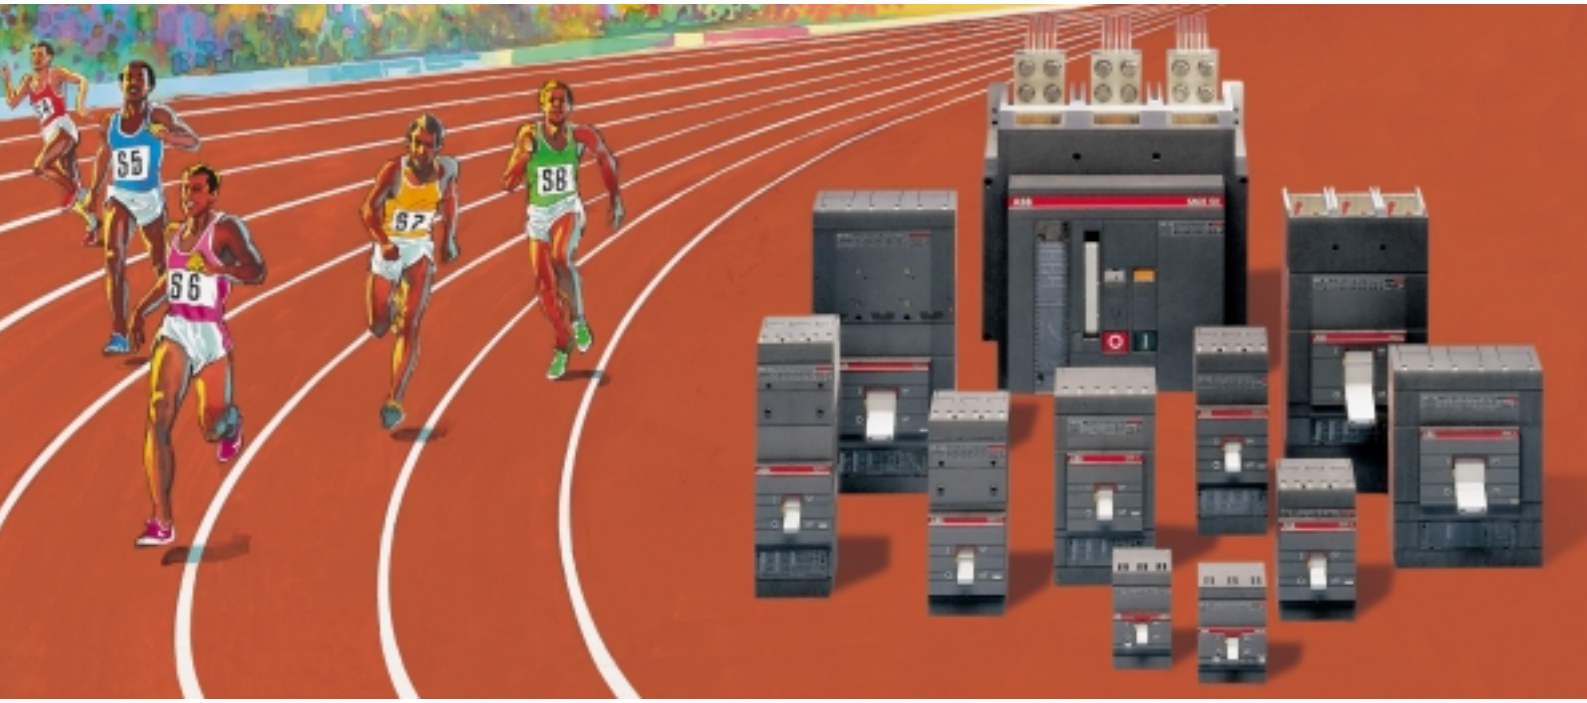

ABB SACE L.V.

Una única serie de interruptores en caja moldeada permite infinitas soluciones

Los interruptores en caja moldeada para baja tensión SACE Isomax S satisfacen una amplia variedad de aplicaciones, que abarca de las pequeñas instalaciones a las grandes plantas industriales de distribución de energía eléctrica. Innovación, tecnología y calidad siempre fueron los principios rectores para el desarrollo de los productos de ABB SACE L.V., y hoy encuentran su máxima expresión en la serie SACE Isomax S, que se presenta con una gama de soluciones aún más exhaustiva, configurando la oferta más completa en el ámbito de los interruptores con caja moldeada.
La serie SACE Isomax S se presenta con ocho modelos de base que, según una lógica modular, se transforman en distintas versiones para formar varias gamas, respondiendo de modo específico y completo a las necesidades de todo tipo de instalación. Están disponibles interruptores para la distribución en corriente alterna o continua, interruptores limitadores de corriente, para protección de motores, de maniobra-seccionadores y diferenciales. A todas estas gamas, que cumplen las normas internacionales IEC 947-2 y EN 60947-2, se suman los interruptores automáticos, para protección de motores y de maniobra-seccionadores, conformes a las normas UL489 y CSA C22.2, gracias a la homologación obtenida de Underwriters Laboratories.

Otra ventaja de la serie es la homogeneidad del suministro: las dimensiones, modalidades de instalación y posibilidades de equipamiento son iguales, independientemente del tipo de gama en el cual se coloque el interruptor, con notables ventajas para el usuario.
La constante evolución de estos productos, que viene ampliando la oferta de SACE Isomax S sin cesar, no se detiene y ofrece numerosas propuestas nuevas.

S2X, por fuera, es idéntico a los S2B/N/S; conserva sus dimensiones, sistemas de fijación y posibilidades de equipamiento y personalización. Gracias a soluciones técnicas particulares, como el doble corte por polo, ofrece unas prestaciones excepcionales en lo que respecta a poder de corte y capacidad de limitación de la corriente de defecto y de la energía específica pasante. La versión S2X 80, con relé sólo magnético 13xIth, está particularmente indicada para la protección de motores, mientras que la versión S2X 100, con relé termomagnético regulable, puede utilizarse en cualquier ámbito donde también se precise una protección contra sobrecargas.

Los interruptores S4 a S7 están equipados con el relé electrónico PR212/MP, específicamente proyectado para el arranque y la protección de los motores. Estos dispositivos aseguran una salvaguardia completa y avanzada, y permiten realizar coordinaciones optimizadas que redundan en cuantiosos ahorros de tiempo, espacio y dinero.

La nueva gama para aplicaciones a 1000 V con corriente alterna extiende aún más los límites de aplicación de los interruptores en caja moldeada, y sintetiza cabalmente la continua evolución de la serie SACE Isomax S y la elevada calidad técnica que la distingue.

El nuevo mando con solenoide para S1-S2 perfecciona la maniobra a distancia de toda la gama SACE Isomax S. Disponible en varias tensiones de alimentación y en dos versiones distintas (para montaje frontal o adosado al interruptor), ofrece una elevada velocidad de maniobra y puede utilizarse para la gestión centralizada de la instalación, así como para la conmutación entre red de servicio y de emergencia.

Notas

1) Todas las versiones con Icu=35 kA están certificadas para 36 kA.
2) Para interruptores S3 N/H/L, S4 N/H/L, S5 N/H y S6 N/S/H, la prestación porcentual de Ics a 690 V se reduce un 25%.
3) Los interruptores en versión extraíble se suministran con el frontal para mando por palanca o con los accesorios alternativos a éste como, por ejemplo, el mando giratorio o el mando a motor.
4) Para el interruptor S5, la versión enchufable se encuentra disponible solamente para la corriente asignada permanente de 400 A (S5 N/H/L 400)
5) El interruptor SACE S3 con poder de corte L a 690 V sólo se puede alimentar por la parte superior.

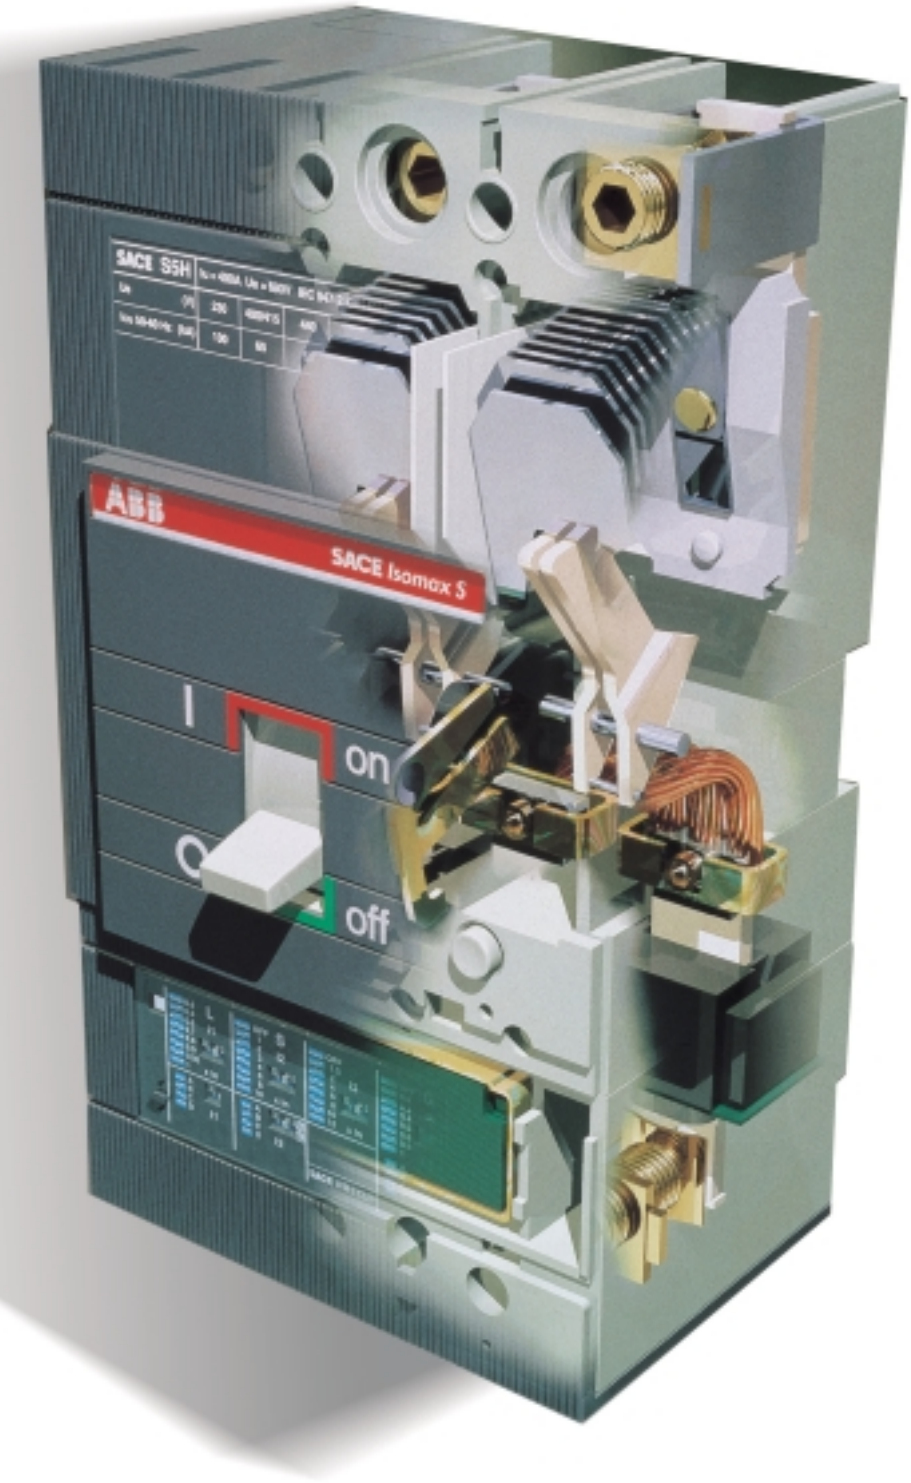
Modularidad y prestaciones IEC 947-2. Una serie completa y coordinada



La gama de interruptores automáticos de caja moldeada SACE Isomax S conformes a la normativa IEC 947-2, se articula en ocho tamaños básicos con corrientes permanentes asignadas de 125 a 3200 A y poder de corte de 16 a 120 kA (380/415 V).
La selección del modelo permite identificar de manera fácil e inmediata las características eléctricas fundamentales; y la selección del relé de sobreintensidad, el tipo de aplicación.

Utilización en corriente alterna
Para la protección de circuitos en corriente alterna están disponibles los interruptores automáticos SACE S1, S2 y S3 equipados con relés termomagnéticos y los interruptores automáticos SACE S4, S5, S6, S7 y S8 equipados con relés con microprocesador SACE PR211/P y PR212/P. Están caracterizados por un campo de aplicación de 10 a 3200 A y por una tensión asignada de 690 V.

Utilización en corriente continua
Los interruptores automáticos SACE S1, S2, S3, S5 y S6 equipados con relés termomagnéticos se utilizan para la protección de circuitos en corriente continua, con un campo de aplicación

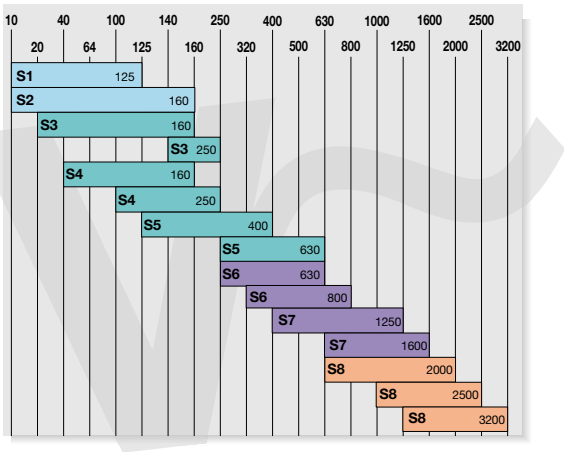
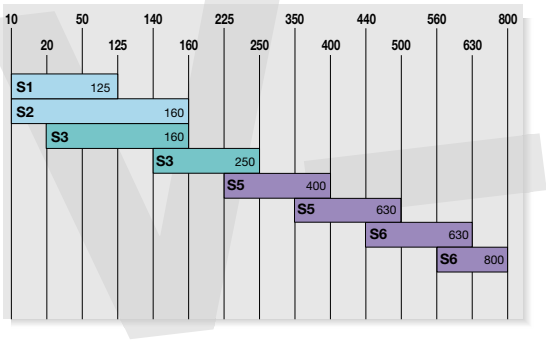
de 10 a 800A.
Con dos polos en serie, los interruptores automáticos SACE Isomax S se pueden utilizar con unas tensiones asignadas de 250 y 500 V y poderes de corte hasta 100 kA (250 V c.c.) y 65 kA (500 V c.c.); mientras que, con los interruptores automáticos SACE S3, S5 y S6 con 3 polos en serie, se puede alcanzar una tensión asignada de 750 V y poderes de corte hasta 50 kA.

Protección de generadores
Para la protección de los generadores, cuyas corrientes de defecto son extremadamente bajas (en el orden de 3 veces la corriente asignada), a la disponibilidad de los relés electrónicos S4 a S7 se suma ahora el modelo S3, con protección termomagnética dedicada, corriente térmica regulable Ith = 0,7…1 x In y umbral magnético fijo Im = 3 x In.

Gama hasta 1000 V
En el ámbito de los interruptores en caja moldeada y abiertos, ABB SACE L.V. propone una novedad con las gamas específicas de interruptores automáticos para aplicaciones en corriente alterna de hasta 1000 V. Los sectores típicos de empleo son las instalaciones en minas, túneles viarios o ferroviarios, tracción y usos industriales en general. Los interruptores están disponibles en versión tripolar, con relés termomagnéticos regulables o electrónicos, y tienen las mismas dimensiones que las versiones estándares. Pueden combinarse con los principales accesorios disponibles para la serie Isomax.



Campo de aplicación de los interruptores automáticos en corriente alterna



Campo de aplicación de los interruptores automáticos en corriente continua

Seguridad y funcionalidad
El doble aislamiento, el bloqueo de la puerta de la celda del cuadro, la extracción con la puerta cerrada son algunas de las características que permiten trabajar con plena seguridad a los operarios y que mejoran la funcionalidad de los aparatos instalados en el cuadro. Además, con la introducción de la tecnología electrónica digital SACE Isomax S se ha podido añadir, a las tradicionales funciones de protección propias de los relés termomagnéticos, otras funciones como la protección contra cortocircuito selectiva, la protección contra defectos a tierra, el control y la comunicación.

Interruptores automàticos en caja moldeada limitadores de corriente IEC 947-2. Potencia y velocidad.

Los interruptores automáticos SACE S2X 100, S3X, S4X y S6X constituyen la gama de interruptores automáticos de caja moldeada SACE Isomax S limitadores de corriente para aplicaciones de 1 a 630 A.
El interruptor automático limitador sirve para "limitar" al máximo la energía específica pasante en caso de cortocircuito y salvaguardar, así, la integridad de los circuitos y de los aparatos situados aguas abajo. El sistema de corte permite interrumpir con extrema rapidez corrientes de cortocircuito con valores elevados; además, gracias a la configuración especial del sistema, permite limitar los valores de cresta de las corrientes de defecto a valores sensiblemente inferiores a los de las corrientes de cortocircuito previstas en el punto de instalación. La rapidez de apertura reduce las solicitaciones electrodinámicas que se producen en los interruptores situados aguas abajo en caso de defecto. Se encuentran disponibles en ejecución fija, enchufable o extraíble y se pueden utilizar todos los accesorios de los correspondientes interruptores automáticos.

Aplicaciones
Están indicados para todos los tipos de instalaciones (civiles, industriales, terciario) así como en los equipamientos a bordo de naves, minas, plataformas petrolíferas y, en general, donde se puedan producir corrientes de cortocircuito de fuerte intensidad, hasta 200 kA a 380/415 V c.a. debido a las elevadas potencias de los transformadores y generadores. Se pueden utilizar como interruptores automáticos generales colocados aguas abajo de la fuente de alimentación y en instalaciones en las que la continuidad de servicio no es un requisito fundamental y se prevé la protección de acompañamiento (back-up) que permite el uso aguas abajo de interruptores con poder de corte inferior a la corriente de cortocircuito prevista en el punto de instalación.

Tensión de servicio y poder de corte
Los interruptores automáticos limitadores de corriente SACE Isomax S son conformes a las normas IEC 947-2. Se caracterizan por una tensión asignada de servicio Ue de 690 V c.a. y el poder asignado de corte último en cortocircuito Iu es de 200 kA a 380/415 V c.a., de 75 kA a 690 V c.a. para S3X, S4X, S6X y de 70 kA a 440 V para S2X 100.
También se pueden realizar protecciones selectivas a pesar de los reducidos tiempos de corte en caso de cortocircuito.

Aptitud al seccionamiento

En la posición de abierto, el interruptor automático garantiza el seccionamiento del circuito en conformidad con la norma IEC 947-2. Las distancias de aislamiento redundantes garantizan la ausencia de corrientes de fuga y tensión de ensayo dieléctrico a posibles sobretensiones entre entrada y salida.

Dimensiones reducidas

La unificación de la profundidad de los interruptores (en 70 mm para S2X 100 y 103,5 mm para S3X, S4X y S6X), la estandarización de las alturas y la ulterior reducción de las anchuras respecto a la de la gama SACE Limitor facilitan la instalación en cuadros y permiten normalizar las estructuras de soporte.

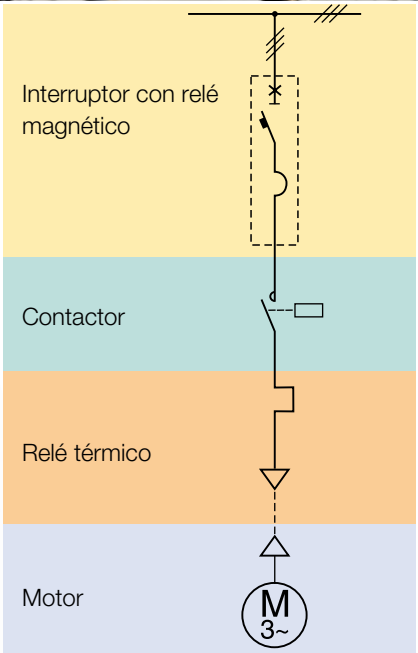
(1) Para S3X con regulación R 32, Icu (690 V~) = 50 kA y Ics = 100%Icu. (2) El valor de Ics a 500/690 V para S3X, S4X y S6X se reduce un 25%.

Interruptores automáticos para protección de motores IEC 947-4. Protección a la medida de su motor



Protección y arranque de los motores asíncronos trifásicos

El arranque, la maniobra y la protección de los motores asíncronos trifásicos son operaciones fundamentales para su uso correcto. El sistema tradicional que se emplea para este fin comprende tres dispositivos: un interruptor para la protección contra cortocircuitos, un relé térmico para protección contra sobrecargas y falta o desequilibrio de fase, y un contactor para maniobrar el motor. El conjunto debe ser capaz de afrontar adecuadamente los problemas que surgen a la hora del arranque.
En particular, para elegir estos dispositivos deben tenerse en cuenta diversos factores, como:
- potencia del motor
- esquema de arranque
- tipo de motor (con rotor de jaula o devanado)
- corriente de defecto en el punto de la red

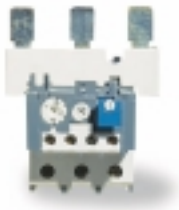
[2] Para interruptores S3 N/H/L, S4 N/H/L, S5 N/H y S6 N/S/H, la prestación porcentual de Ics a 690 V se reduce un 25%.



donde está instalado el motor.
ABB SACE L.V. propone una amplia gama de interruptores que, implementando exclusivamente la protección contra cortocircuitos, son idóneos para el uso dentro de arrancadores protegidos de tipo tradicional.
El nuevo SACE S2X 80, con la protección magnética fija 13 veces superior a la corriente asignada de servicio, es un interruptor extremadamente compacto y dotado de prestaciones excepcionales en lo que respecta a poder de corte y limitación de la energía específica pasante.
Muy fácil y rápido de instalar, tiene las mismas posibilidades de equipamiento y personalización que los interruptores S2B/N/S. Puede utilizarse en un vasto campo de arranques, de 0,37 kW a 37 kW y de 400 V-50 kA hasta 690 V-50 kA.
Los interruptores automáticos SACE S3N/H/L 160/250 y el interruptor limitador de corriente S3X 125/200 llevan montado un relé sólo magnético, regulable de 4 a 12 veces la corriente asignada de servicio. Cubren coordinaciones de 37 a 132 kW y, gracias a la elevada flexibilidad que les confiere el amplio rango de regulación del umbral magnético, aseguran la mejor protección para el motor.
Los SACE S4 160/250, S5 400/630, S6 630/800 y S7 1250/1600, con los diversos niveles de poder de corte N-S-H-L, así como los limitadores de corriente S4X y S6X, pueden equiparse con el relé electrónico con microprocesador PR211/P (I). Se utilizan principalmente en motores de elevada potencia y, gracias a la protección contra cortocircuitos regulable de 1,5 a 12 veces, permiten elegir el valor de intervención ideal para cada tipo de motor.

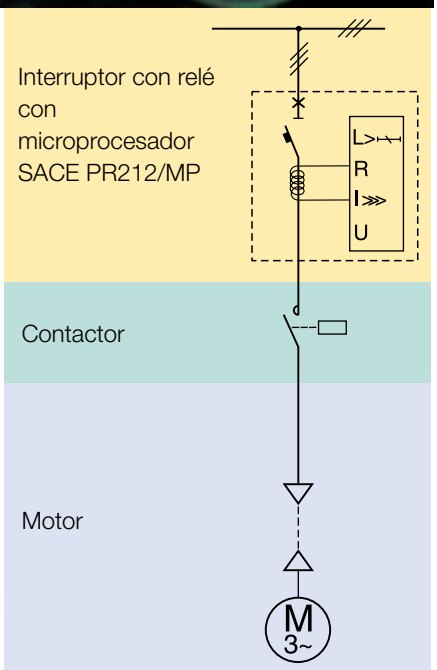
Relés electrónicos SACE PR212/MP IEC 947-4. La evolución de la protección de motores



Los interruptores SACE Isomax S4N-H-L 160/250, S5N-H-L 400, S6N-H-L 800, S7S-H-L, S4X 250 y S6X 400/630 pueden equiparse con relés electrónicos SACE PR212/MP, realizados con tecnología de microprocesador. Esto permite, por una parte, obtener funciones que garantizan una elevada precisión de intervención, extrema fiabilidad e insensibilidad a los agentes externos; y, por la otra, implementar nuevas y sofisticadas protecciones que, integradas en el interruptor, constituyen una solución tecnológicamente avanzada para el arranque y la protección de motores.
SACE PR212/MP es tan sofisticado en su proyecto como sencillo e inmediato en el uso. Las diversas curvas de funciones, con múltiples regulaciones en umbrales y tiempos, permiten trazar una curva general de intervención realmente próxima a la curva de arranque del motor, optimizando la protección.

(1) Todas las versiones con Icu=35 kA están certificadas para 36 kA.

(2) Para interruptores S4 N/H/L, S5 N/H y S6 N/S/H, la prestación porcentual de Ics a 690 V se reduce un 25%.

SOBRECARGA: FUNCIÓN L

Un modelo térmico, almacenado en el microprocesador, permite correlacionar las sobrecorrientes verificadas en la línea de alimentación con los niveles de temperatura alcanzados en el cobre y en el hierro del motor (patente internacional de ABB SACE L.V.). La protección es conforme a las normas internacionales sobre seguridad de motores, IEC947-4-1, y ofrece cuatro clases distintas de arranque: 10A, 10, 20 y 30. Además, está compensada en temperatura y es sensible a la falta o al desequilibrio de fase, según la norma.

ROTOR BLOQUEADO: FUNCIÓN R

La función R protege el motor ante un posible bloqueo del rotor durante el funcionamiento. Esta protección se desactiva automáticamente durante la fase de arranque y después se reactiva. De este modo se evitan intervenciones no deseadas debidas a la corriente de subtransitorio y, al mismo tiempo, se protege el motor y la instalación durante el funcionamiento.

CORTOCIRCUITO: FUNCIÓN I

Esta protección interviene en escasos milisegundos cuando se verifica un cortocircuito. El microprocesador, además, discrimina el arranque, evitando que el interruptor se abra inoportunamente a causa de la corriente de pico (patente internacional de ABB SACE L.V.).

FALTA O DESEQUILIBRIO DE FASE: FUNCIÓN U

La falta de fase o los desequilibrios de absorción son detectados por el relé electrónico que controla todas las corrientes de fase.
La función U es una protección adicional que se suma a la sensibilidad normal a estos fenómenos, impuesta por la norma y garantizada por la función L. Si la corriente de una o dos fases se hace inferior al umbral prefijado de 0,4 veces la corriente térmica, y permanece así durante más de 4 segundos, el relé se dispara.

Soluciones coordinadas con el sistema ABB
Esta avanzada solución —un arrancador formado por un interruptor SACE Isomax S con PR212/MP y un contactor ABB— ofrece numerosas ventajas además de una perfecta protección del motor. En primer lugar, un notable ahorro de tiempo, espacio y dinero, gracias al hecho de que no hace falta utilizar un relé térmico externo.
Además, la serie SACE Isomax S y la nueva línea de contactores A-Line ABB son la base de una nueva generación de aparatos, específicamente proyectados para componer un sistema de productos perfectamente integrable según las distintas necesidades de aplicación.
El interruptor automático y el contactor tienen las mismas dimensiones en anchura y profundidad, y un sistema de instalación excepcionalmente sencillo y compacto.

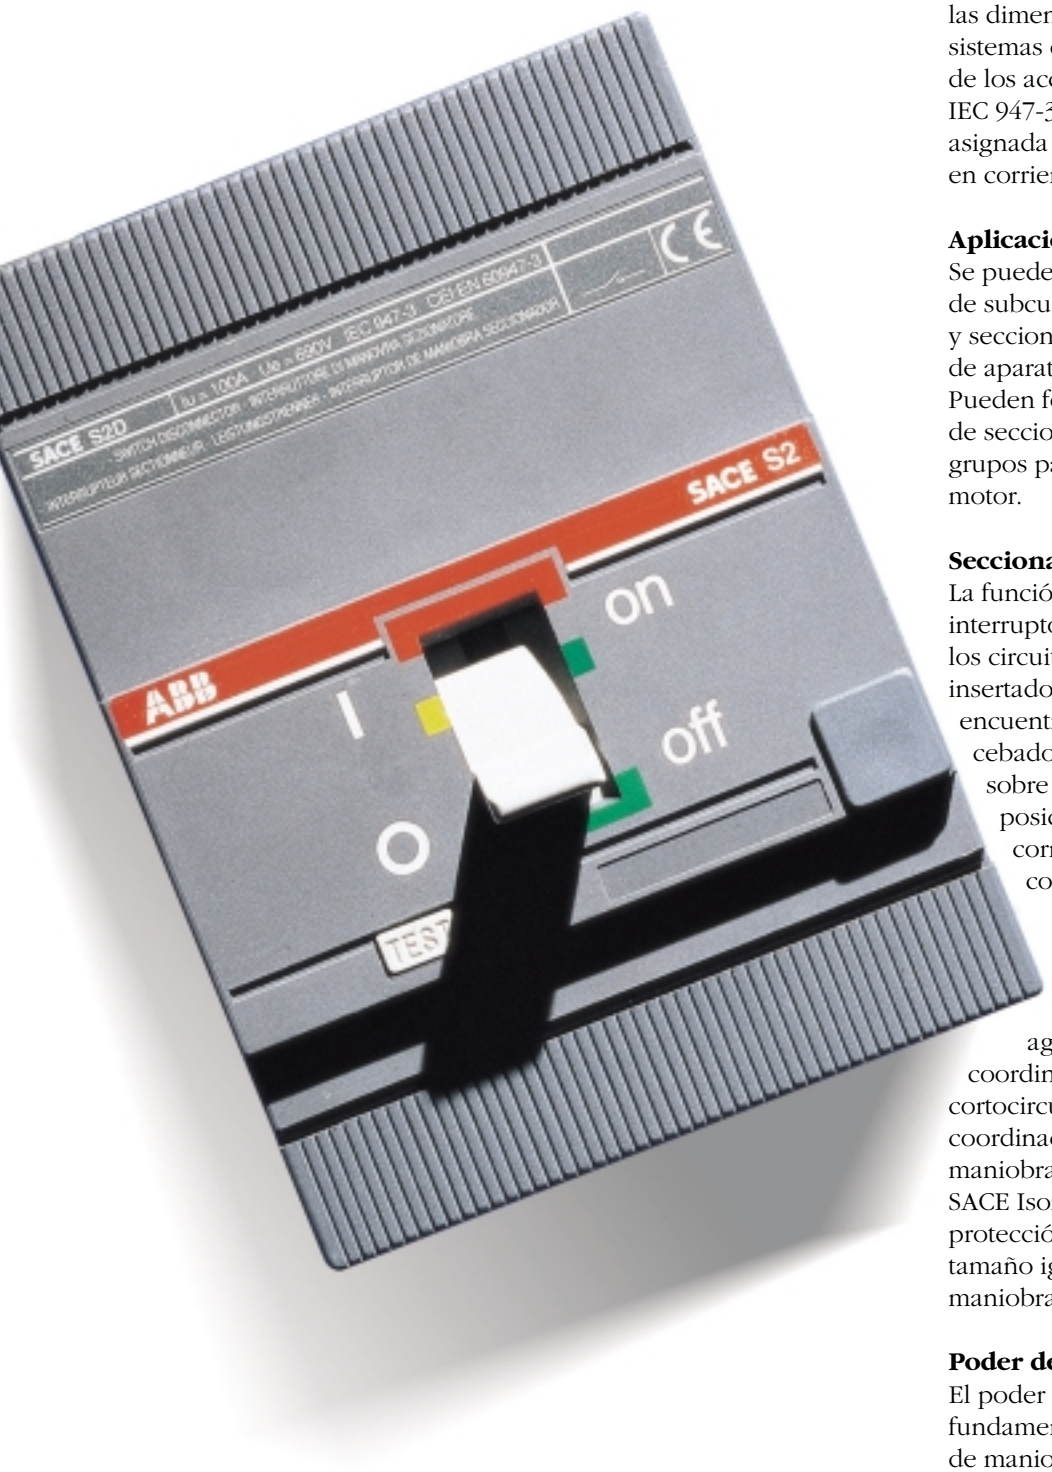
Además de la combinación clásica interruptor-contactor-relé térmico, los interruptores SACE Isomax S para protección de motores, a partir del modelo S4, se combinan sólo con el contactor (ejemplo de composición entre S5H con PR212/MP y contactor serie A modelo A300-30).

Interruptores de maniobra-seccionadores IEC 947-3. Maniobras en plena seguridad



Los interruptores de maniobra-seccionadores derivan de los correspondientes interruptores automáticos, de los que conservan inalteradas las dimensiones generales, las ejecuciones, los sistemas de fijación y la posibilidad de montaje de los accesorios. Son conformes a la norma IEC 947-3. Se caracterizan por una tensión asignada de 690 V en corriente alterna y 750 V en corriente continua.

Aplicaciones
Se pueden utilizar como interruptores generales de subcuadros, como dispositivos de maniobra y seccionamiento para líneas, barras o grupos de aparatos o como acopladores de barras. Pueden formar parte de dispositivos generales de seccionamiento de grupos de máquinas o de grupos para la maniobra y protección de un motor.

Seccionamiento
La función principal que realizan estos interruptores consiste en el seccionamiento de los circuitos en los que se encuentran insertados. Los contactos, una vez abiertos, se encuentran a una distancia que impide el cebado de un arco, respetando las normativas sobre la aptitud al seccionamiento. La posición de la palanca de mando corresponde exactamente a la de los contactos (maniobra positiva).

Protección
Todo interruptor de maniobra-seccionador tiene que estar protegido aguas arriba por un dispositivo coordinado que lo proteja contra los cortocircuitos. La siguiente tabla de coordinación indica para cada interruptor de maniobra-seccionador el interruptor automático SACE Isomax S que puede realizar la función de protección. Se trata siempre de aparatos de tamaño igual o inferior al del interruptor de maniobra-seccionador.

Poder de cierre
El poder de cierre es una prestación de fundamental importancia, ya que un interruptor de maniobra-seccionador tiene que ser capaz de soportar sin destruirse las solicitaciones dinámicas, térmicas y de corriente que pueden manifestarse durante el cierre, hasta las condiciones de cierre con cortocircuito.

Resistencia en posición de cerrado

Identifica la capacidad de mantener la posición de cerrado para sobrecorrientes de corta duración. Se trata de un parámetro significativo que califica las prestaciones de estos aparatos.

Relés diferenciales. Una unión coordinada

Los interruptores automáticos diferenciales combinan en un único aparato la función de protección contra sobreintensidades y la función diferencial; actúan tanto debido a sobrecarga / cortocircuito como por fuga de corriente a tierra.
Los interruptores diferenciales “puros” que se obtienen con los interruptores de maniobra-seccionadores, sólo son sensibles a la corriente de defecto a tierra
Permiten el control continuo del estado de aislamiento de la instalación asegurando una protección eficaz contra los riesgos de incendio y explosión y, en los casos con dispositivos con IDn ≤ 30 mA, asegurando la protección de las personas contra los contactos directos e indirectos como integración de las medidas obligatorias previstas por las normativas y las prescripciones de prevención de los accidentes.

Relé diferencial polarizado SACE RC210
Para los interruptores SACE S1 está disponible el relé diferencial polarizado SACE RC210/1 para el montaje colateral sobre perfil DIN

50022, en las versiones adecuadas para corrientes diferenciales alternas senoidales (AC), con umbrales de actuación por defecto diferencial de 300 mA y 500 mA, corrientes asignadas permanentes de 63 A y 125 A y tensiones de funcionamiento hasta 500 V.
El relé diferencial polarizado está disponible como bloque a instalar colateralmente en la parte derecha del interruptor y actúa directamente en el dispositivo de disparo. Está dotado con un pulsador de prueba para el control periódico del relé.

Relés diferenciales SACE RC211 y RC212
Los relés diferenciales SACE RC211 y RC212 se pueden montar en posición colateral o inferior tanto en los interruptores automáticos SACE Isomax S1, S2 y S3 como en los interruptores de maniobra-seccionadores SACE S3D. Han sido realizados con tecnología electrónica-analógica. No requieren alimentación auxiliar ya que se alimentan directamente mediante la red a través del interruptor y el funcionamiento está garantizado incluso con una sola fase en tensión y en presencia de corrientes unidireccionales pulsantes con componentes continuas. Un pulsador de prueba permite controlar las condiciones de funcionamiento del relé diferencial.
Los relés diferenciales han sido realizados en conformidad con la norma IEC 947-2 apéndice B, IEC 255-4 e IEC 1000 para la protección contra los disparos intempestivos, IEC 755 para la insensibilidad a las componentes continuas de corriente.
Los relés SACE RC211 y SACE RC212 actúan directamente en el interruptor mediante un solenoide de apertura suministrado con el relé que se tiene que alojar en el correspondiente hueco localizado en la zona del tercer polo.

Relé diferencial de cuadro SACE RCQ
Está aconsejado para el uso en presencia de corrientes de defecto a tierra exclusivamente alternas, para corrientes alternas y/o pulsantes con componentes continuas y para realizar la selectividad diferencial. Se puede combinar con todos los interruptores SACE Isomax S, se instala en los cuadros con toroidal separado para montar exteriormente en los conductores de la línea.
Particularmente indicado para las aplicaciones en las que se desee efectuar un sistema de protección diferencial coordinado con los diferentes niveles de distribución, desde el cuadro principal al servicio final.

En el campo de los interruptores automáticos en caja moldeada SACE Isomax S, conformes a las normas UL489 y CSA22.2, la oferta SACE Isomax S incluye tres gamas; una de interruptores automáticos para la distribución de potencia, equipados con relés termomagnéticos o electrónicos, otra de interruptores automáticos con relés solo magnéticos (Motor Control Protection – MCP) para protección de motores, y la tercera de interruptores de maniobra (Moulded Case Switch – MCS) para utilizar como seccionadores o dispositivos de maniobra para líneas, barras o partes de instalaciones.
La propuesta de SACE Isomax S aprobada según normas UL/CSA se completa con la introducción de tres nuevos modelos. De esta manera aumentan las posibilidades para los clientes que trabajan en mercados sujetos a estas normas, teniendo a su disposición una gama entera de interruptores en caja moldeada con corrientes asignadas que van de 100 a 2500 A y poderes de corte, a 480 V c.a., que pueden alcanzar los 100kA.
La presentación del modelo S1, además de ampliar el campo de corrientes asignadas hacia valores más bajos, permite satisfacer todas las aplicaciones típicas de la subdistribución de potencia, que exigen interruptores de tamaño reducido pero con gran versatilidad de equipamiento e instalación.
Las opciones se incrementan también con la introducción de nuevas características para S3, Iu = 225 A, con tres niveles de poder de corte (N/H/L), hasta unos valores de tensión de servicio Ue = 480 V c.a. y 500 V c.c.

Por último, cabe destacar la novedad representada por el interruptor S8 según norma UL/CSA, que extiende la gama hacia los valores mayores de corrientes asignadas. Isomax S8V 1600, 2000 y 2500 pueden instalarse inmediatamente después de las fuentes de alimentación en sistemas de baja tensión, y son idóneos para funcionar con seguridad en las más severas condiciones de uso imperantes en las instalaciones modernas. Las elevadas prestaciones, amplia flexibilidad de equipamiento, facilidad de coordinación con los dispositivos montados en puntos posteriores de la línea y la posibilidad de limitar la profundidad de los cuadros gracias al tamaño pequeño del interruptor hacen de Isomax S8 una solución particularmente ventajosa.

Soluciones inteligentes para una gama completa y personalizada

Modularidad y compacidad

Reduce las dimensiones de los cuadros eléctricos

La modularidad con la que se han concebido las gamas de los interruptores automáticos, de los limitadores de corriente, de los interruptores de maniobra-seccionadores y de los interruptores para protección de motores, facilita la instalación en el interior de las celdas.
Gracias al uso de nuevos materiales y a un estudiado proyecto de los diferentes modelos, los interruptores SACE Isomax S permiten reducir las dimensiones de los cuadros eléctricos:
• a igualdad de prestaciones, los volúmenes ocupados por los interruptores se reducen hasta el 50% con respecto a la serie precedente;
• toda la gama, articulada en ocho modelos y realizada con sólo cuatro profundidades (70 mm para S1 y S2; 103,5 mm para S3 ... S6; 138,5 mm para S7; 242 mm para S8), permite la normalización de las estructuras de soporte, la estandarización de los cuadros y la instalación en estructuras prefabricadas;
• el frontal, normalizado para grupos de interruptores (45 mm para S1 ... S5; 105 mm para S3 ... S7), permite la combinación de los diferentes modelos gracias a la misma ventana del cuadro;
• la homogeneidad dimensional, las posibilidades de conexión gracias a la variedad de terminales disponibles facilita las conexiones mediante sistemas de barras o conexiones con cable.

Cualquier posición de instalación

Máxima flexibilidad durante la elaboración del proyecto y el montaje

Los interruptores automáticos SACE Isomax S se pueden instalar tanto en posición horizontal como vertical, sin que esto perjudique sus prestaciones.
La alimentación se puede efectuar mediante los terminales superiores o los inferiores.
El montaje se puede efectuar en la placa de fondo del cuadro o, hasta el modelo S5, sobre perfil DIN.

Grado de protección

Protección asegurada contra los contactos directos accidentales

El grado de protección de los interruptores en ejecución fija, enchufable o extraíble es de IP20. IP30 para los interruptores instalados en el cuadro.
Si se añade un mando giratorio reenviado, montado en la puerta de la celda, se alcanza el grado de protección IP54. Las partes fijas de los interruptores enchufables o extraíbles presentan, hacia el frente, un grado de protección IP20.

Nuevo sistema de corte

Limita la presencia y la peligrosidad del arco

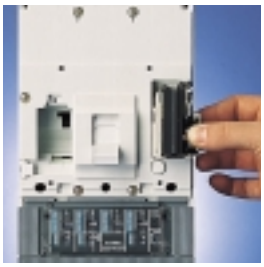
El corte de la corriente se efectúa favoreciendo la sinergia de tres factores que intervienen en la extinción del arco en el menor tiempo posible. Dichos elementos son:
• la velocidad de apertura de los contactos, aumentada gracias a un nuevo sistema cinemático que abre los contactos instantáneamente;
• la acción dinámica de soplado ejecutada en el arco por el campo magnético;
• la estructura de la cámara de arco.
Gracias a la considerable contención del tiempo de apertura, el interruptor automático limita drásticamente el valor de la energía específica pasante salvaguardando los aparatos, los servicios y los conductores situados aguas abajo.

Maniobra positiva

Garantiza las señalizaciones correctas

Los estados de “abierto” y “cerrado” están indicados por la posición asumida por la palanca de maniobra. La posición intermedia indica la apertura por la actuación de los relés. En todos los casos, las señalizaciones mecánicas corresponden siempre a las posiciones reales de los contactos móviles del interruptor.
El mecanismo de mando del interruptor es del tipo con disparo libre independiente de la presión sobre la palanca y de la velocidad de la operación.

Doble aislamiento



Segregación entre los circuitos de potencia y los circuitos auxiliares

Todos los interruptores, a partir del modelo S3, han sido realizados con la técnica del doble aislamiento.
La ubicación de cada accesorio eléctrico está completamente segregada del circuito de potencia; de esta manera, se evita todo riesgo de contacto con las partes activas y se aumentan, así, las condiciones de seguridad del operador en la gestión y la inspección de las instalaciones.
Entre las partes activas interiores, el interruptor presenta, además, un aislamiento redundante tanto por el espesor de los materiales como por las distancias, superiores a las requeridas por las normas IEC y conforme a lo previsto por la práctica americana.

Extracción con la puerta cerrada

Máxima seguridad para el operador y posibilidad de efectuar cuadros a prueba de arco interno

Este sistema, presente por primera vez en una serie de interruptores automáticos de caja moldeada, a partir del modelo S3, permite la inserción y la extracción del interruptor con la puerta de la celda cerrada.
Esta característica aumenta la seguridad del operador y permite realizar cuadros de baja tensión a prueba de arco interno.
La extracción sólo se puede efectuar con el interruptor automático abierto, utilizando una manivela de extracción suministrada con el interruptor en ejecución extraíble.

Mantenimiento fácil y seguro

Reduce los tiempos de mantenimiento y garantiza la seguridad

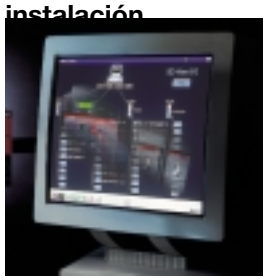
Con el interruptor fuera de servicio es posible controlar directamente el estado de las piezas interiores y de los componentes activos del interruptor. Las cámaras de arco y los contactos fijos y móviles son accesibles tras quitar simplemente la tapa del interruptor.
Esta operación, facilitada por el número limitado de componentes, reduce los tiempos de mantenimiento y garantiza un nivel superior de seguridad.

Conformidad con las normas

Normas, homologaciones, certificados y sistemas de calidad empresariales

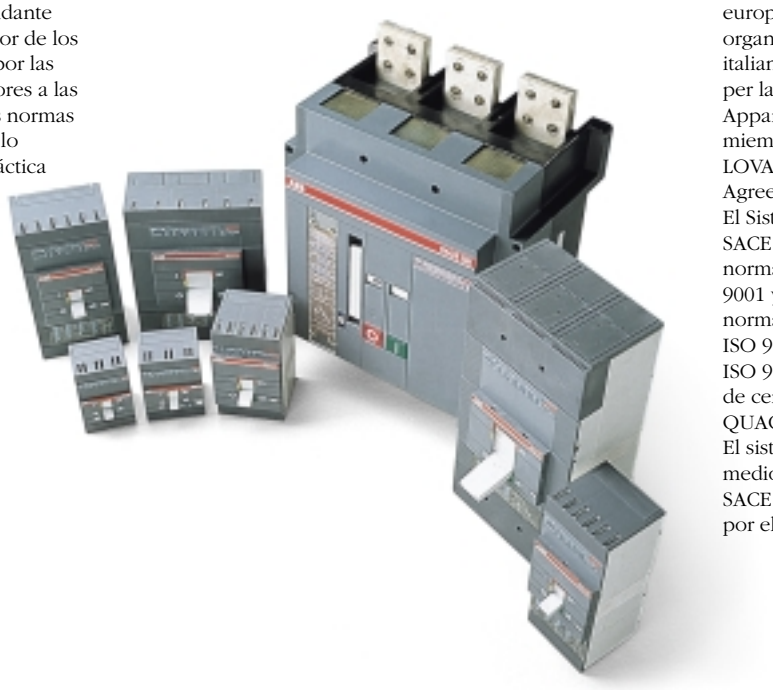
Los interruptores SACE Isomax S y sus accesorios responden a la normas internacionales IEC 947-2, EN 60947-2 (armonizadas en 17 países del CENELEC), UNE EN 60947-2 e IEC 1000 y son conformes a las directivas comunitarias de "Baja Tensión" (LVD) nº 73/23 EEC y de "Compatibilidad electromagnética" (EMC) nº 89/336 EEC.
Los certificados de conformidad del producto con las normas anteriormente citadas, son expedidos, según la establecido por la norma europea EN 45011, por el organismo de certificación italiano ACAE (Associazione per la Certificazione delle Apparecchiature Elettriche), miembro de la organización LOVAG (Low Voltage Agreement Group).
El Sistema Calidad de ABB SACE L.V. es conforme a la norma internacional ISO 9001 y a las equivalentes normativas europeas EN ISO 9001 e italianas UNI EN ISO 9001. El tercer instituto de certificación es el RINA-QUACER.
El sistema de gestión del medio ambiente de ABB SACE L.V. está certificado por el RINA.

La electrónica al servicio de la instalación



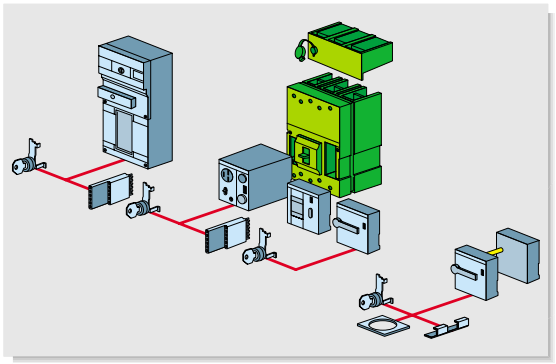
Fiabilidad, precisión e integración en los sistemas de supervisión

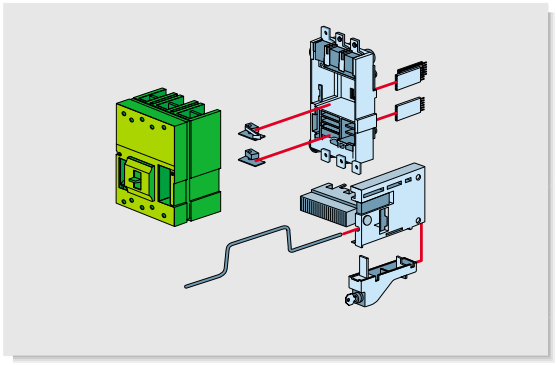
Los relés con microprocesador están caracterizados por la precisión y la fiabilidad derivadas de una atenta realización del proyecto de los componentes y de los algoritmos que realizan las funciones de protección.
La electrónica digital ha permitido realizar funciones como el control y la comunicación para permitir la plena integración de los interruptores en las lógicas de gestión de los sistemas de supervisión y control.
ABB SACE L.V., a la vanguardia en los sistemas de supervisión y control de las instalaciones eléctricas más complejas, propone también la solución más adecuada a las pequeñas instalaciones: el sistema SD-View 810 que, estudiado expresamente para la pequeña y mediana industria, se puede utilizar en un ordenador personal sin ningún tipo de aprendizaje especial.
Aprovechando al máximo la funcionalidad de los relés con microprocesador, SD-View puede dialogar con todos los interruptores ABB SACE L.V., permitiendo controlar el estado de la instalación mediante la memorización continua de los datos, la detección del estado de los interruptores y la señalización de anomalías y los defectos. Al mismo tiempo, permite programar al operador los parámetros de protección y las características de actuación.

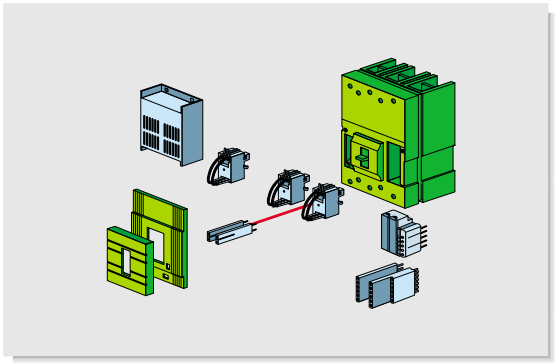


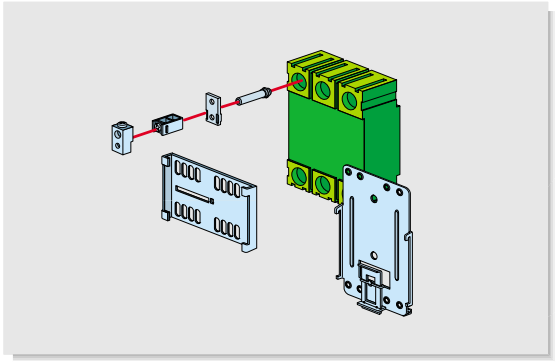
Una gama completa de accesorios. Máxima libertad de personalización

Para la serie SACE Isomax S, la homogeneidad del suministro se traduce en la gran variedad de accesorios unificados por grupos de interruptores.
Los accesorios son los mismos para todas las gamas y se pueden montar sin quitar la tapa del interruptor. Esto permite adaptaciones “in situ” in provocar interrupciones del servicio.
seguridad del personal queda garantizada en las las condiciones gracias al aislamiento de sede de los accesorios con relación a las ezas bajo tensión.









Commande par poignée rotative

Permite una maniobra de apertura y cierre del interruptor más fácil.
Está preparado para un bloqueo por candados (de serie), con posibilidad de montar el bloqueo a llave y el bloqueo de la puerta de la celda (de serie para SACE S1 y S2).

Relé de apertura

Permite la apertura a distancia del interruptor.

Relé de mínima tensión

Provoca la apertura del interruptor en caso de una sensible disminución o falta de tensión de alimentación.
También se encuentra disponible en versión retardada.

Mando con motor

Permite abrir y cerrar el interruptor a distancia.
También es posible aplicar el bloqueo con llave. Se realiza en la versión con solenoide para S1 y S2 de acción directa para los interruptores SACE S3, S4 y S5, y en la de acumulación de energía para los interruptores SACE S6 y S7.

Unidad de diálogo y unidad de señalización

Permite la comunicación bidireccional con los sistemas de gestión y control de la instalación eléctrica.
Siempre se combina con:
• la unidad de actuación para la apertura y el cierre del interruptor desde el sistema de gestión.
Se puede completar con:
• la unidad de señalización para la visualización de las informaciones proporcionadas por el relé con microprocesador.

Contactos auxiliares y de posición

Indican la señalización de
• interruptor abierto - cerrado;
• interruptor abierto por la actuación de los relés;
• interruptor insertado - extraído.
Se encuentran disponibles con contactos conmutados.

Software y reglas. Instrumentos de selección y proyectación

Para la elaboración de los proyectos y el dimensionamiento de las instalaciones eléctricas se encuentran disponibles tres instrumentos de trabajo muy útiles (software, el kit de reglas y la guía para la selección de aparamenta de baja tensión) que facilitan los cálculos, aseguran la conformidad del equipo con las normativas y disminuyen los riesgos de error.
Cada CD-Rom incluye los tres productos software principales desarrollados por ABB SACE L.V. y ABB Elettrocondutture llamados: D.O.C., C.A.T.s y DMB/Win.
El D.O.C. (Design Optimization & Compulation) es un sistema de dimensionamiento optimizado para instalaciones industriales de baja tensión y puede sugerir las soluciones proyectuales más correctas correspondientes a los cables, barras y dispositivos de protección.
Permite al proyectista desarrollar rápidamente una documentación para el proyecto clara y completa, conforme con las recientes normativas.
El C.A.T.s. (Computer Aided Technical selection) es un catálogo electrónico y un instrumento técnico de ayuda durante la selección y accesoriamento de cada interruptor.
Mediante un recorrido guiado es posible seleccionar, configurar y solicitar el aparato más indicado a las exigencias de instalación.
El paquete software DMB permite efectuar de manera automática y veloz los presupuestos y la configuración de los cuadros de distribución de las series ArTu y PC de ABB Turati, utilizando principalmente equipos y materiales ABB.
Además, el paquete es perfectamente compatible con las aplicaciones AutoCAD (DMBLT3 y DMBCAD 3.0) específicamente desarrolladas por ABB para el diseño de cuadros y de esquemas eléctricos unifilares.
Cuatro reglas de distintos colores, que constituyen el kit ABB, ayudan a efectuar rápidamente los cálculos de dimensionamiento de la instalación eléctrica.
Es posible efectuar:
- Dimensionamiento de los cables y cálculo de las corrientes de cortocircuito (regla amarilla).
- Verificación de las protecciones contra los contactos indirectos y los cortocircuitos de los cables (regla naranja).
- Coordinación selectiva y de acompañamiento (regla verde).
- Dimensionamiento de las líneas de motor y salidas de los transformadores (regla azul).
Los métodos de cálculo y los datos indicados en las reglas han sido tomados de las vigentes Normas UNE, IEC y NFC y de la práctica en el sector.
La Guja para la selección de aparamenta de baja tensión permite el calculo de la instalación y la optimización técnica y económica en la selección de la aparamenta.
Constituye una herramienta de consulta práctica e imprescindible para proyectistas e instaladores.

SACE Isomax S. Tecnología, innovación y calidad

Usuario. Prestaciones elevadas, fiabilidad, dedicadas a los usuarios

Sería suficiente la historia de ABB SACE L.V., caracterizada por un desarrollo tecnológico continuo, unas soluciones innovadoras y unas selecciones fáciles para las exigencias de las personas que utilizan interruptores automáticos, para servir de referencia en la elección de productos efectivamente válidos.
Sin embargo, para el usuario no es suficiente. Siempre busca lo mejor, lo fiable y lo más seguro.
Ponerse en la óptica del usuario es una estrategia que, durante años, ha permitido a ABB SACE L.V. mejorar continuamente, armonizando las nuevas soluciones técnicas con las exigencias de los usuarios, que exigen a los interruptores automáticos un elevado grado de fiabilidad en el tiempo y, cuando es necesario, la posibilidad de sustituir las piezas averiadas y una especial compatibilidad de las prestaciones de protección con las exigencias, más o menos críticas, de la aplicación.

Proyectista. Más soluciones integradas para cualquier exigencia

Para el proyectista es importante contar con interruptores automáticos que respondan perfectamente a las normativas técnicas internacionales y capaces de efectuar, de manera fiable, cualquier tipo de prestación en los niveles más elevados.
Un proyecto es el fruto de un análisis atento del problema y de la puesta en práctica de ideas originales, basadas en un concreto equilibro de factores concernientes a la funcionalidad, la seguridad, la fiabilidad a lo largo del tiempo y el mantenimiento.
La serie de interruptores automáticos SACE Isomax S ofrece al profesional las soluciones de dimensionamiento, coordinación y flexibilidad de uso que le permiten realizar un proyecto profesional, seleccionando gamas y soluciones para los circuitos concebidas para ser integradas en un sistema completo, satisfaciendo todas las exigencias de instalación y las normativas vigentes.

Encarcado del mantenimiento. Mantenimiento fácil y seguro

Como establecen las normativas y directivas europeas más recientes, el mantenimiento es un factor indispensable en cualquier tipo de instalación.
Los interruptores automáticos SACE Isomax S permiten la inserción de accesorios desde el frente.
En las versiones enchufables y extraíbles se pueden insertar y extraer de la parte fija con gran facilidad.
La disponibilidad de accesorios por grupos de interruptores permite una gestión sencilla y económica de las piezas de recambio necesarias. La racionalidad de fabricación así como la modularidad del diseño permiten intervenciones de sustitución que, a menudo, no requieren especiales adaptaciones ni tan siquiera al pasar de un tipo de interruptor a otro como, por ejemplo, de un interruptor automático a uno limitador.

Instalador y cuadrista. Facilidad de instalación para cualquier instalación

La calidad de los accesorios suministrados con los interruptores automáticos SACE Isomax S; el estudio esmerado antes de la realización del producto, la calidad de la documentación técnica de soporte que ABB SACE L.V. pone a disposición de los instaladores y cuadristas. Estos y otros factores tienen un papel determinante para hacer de un interruptor automático un producto de uso sencillo que se pueda ensamblar, conectar y verificar con facilidad.
La profesionalidad de los instaladores y cuadristas encuentra en la serie de interruptores automáticos SACE Isomax S un partner también profesional ya que se puede gestionar con los máximos niveles de flexibilidad e integración y porque ha sido concebida para garantizar la realización de las soluciones de instalación más avanzadas y simples.

8 Order form

1 Introduction and application

The *MRN3* is a universal mains decoupling device and covers the protection requirements from VDEW and most other utilities for the mains parallel operation of power stations.

- Over/ and undervoltage protection,
- over/ and underfrequency protection,
- extremely fast decoupling of generator in case of mains failure (*MRN3-1*) or
- rate of change of frequency df/dt (*MRN3-2*)

Because of combination of three protectional functions in one device the *MRN3* is a very compact mains decoupling device. Compared to the standardly used single devices it has a very good price/performance ratio.

For applications where the single protection functions are required SEG can offer the single *MR*-relays as follows:

- *MRU3-1* four step independent over-/ and undervoltage protection (also used for generator earth fault protection).
- *MRU3-2* two step independent over-/ and undervoltage protection with evaluation of the symmetrical voltage components.
- *MRF3* four step independent over/ and underfrequency protection and two step frequency gradient supervision df/dt.
- *MRG2* generator mains monitor / vector surge detection.

Important:
For additional common data of all *MR*-relays please refer to technical description "*MR* - Digital Multifunctional Relays".

2 Features and characteristics

- Microprocessor technology with watchdog,
- effective analog low pass filter for suppressing harmonics when measuring frequency and vector surge,
- digital filtering of the measured values by using discrete Fourier analysis to suppress higher harmonics and d.c. components induced by faults or system operations,
- integrated functions for voltage, frequency and vector surge in one device as well as single voltage, frequency and vector surge devices,
- two parameter sets,
- voltage supervision each with two step under-/ and overvoltage detection,
- frequency supervision with three step under-/ or overfrequency (user setting),
- completely independent time settings for voltage and frequency supervision,
- adjustable voltage threshold value for blocking frequency and vector surge measuring,
- display of all measuring values and setting parameters for normal operation as well as tripping via a alphanumerical display and LEDs,
- display of measuring values as primary quantities
- Storage of trip values and switching-off time (t_{CBFP}) of 5 fault occurences (fail-safe of voltage),
- recording of up to eight fault occurences with time stamp
- for blocking the individual functions by the external blocking input, parameters can be set according to requirement,
- user configurable vector surge measurement 1-of-3 or 3-of-3,
- reliable vector surge measuring by exact calculation algorithm,
- suppression of indication after an activation (LED flash),
- free assignment for output relays,
- display of date and time,
- in complience with VDE 0435, part 303 and IEC 255,
- serial data exchange via RS485 interface possible; alternatively with SEG RS485 Pro-Open Data Protocol or Modbus Protocol.

3 Design

3.1 Connections

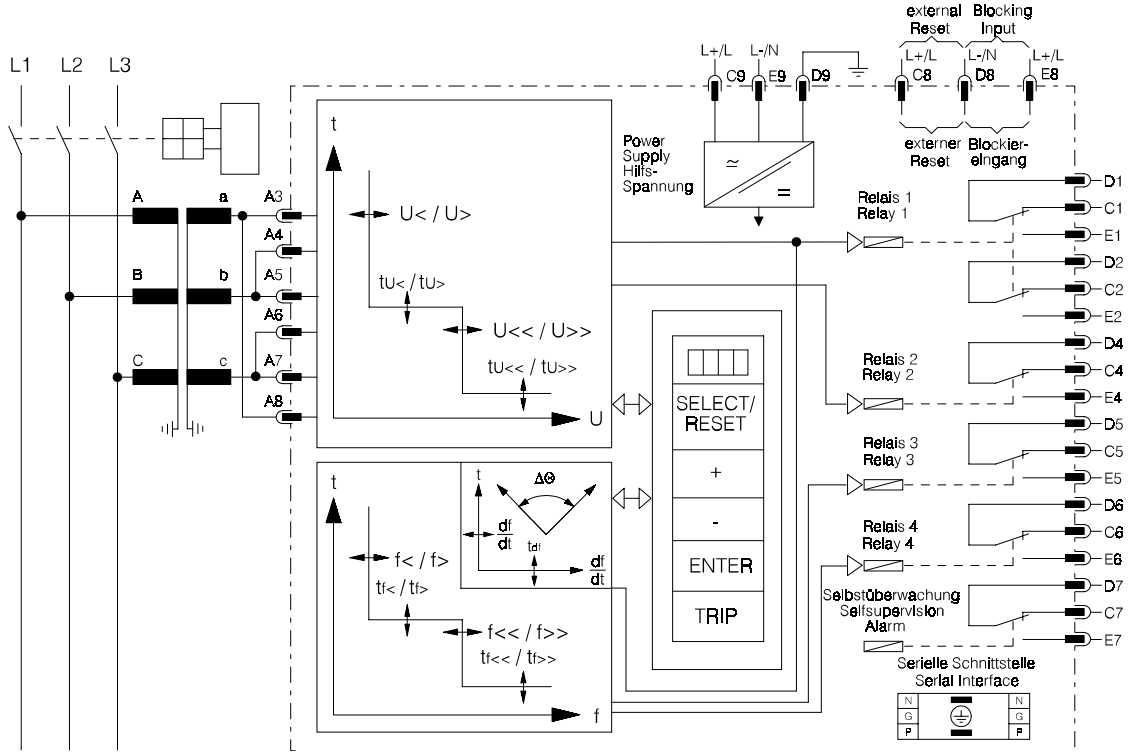

Figure 3.1: Connection diagram MRN3-1 and MRN3-2

3.1.1 Analog input circuits

The analog input voltages are galvanically decoupled by the input transformers of the device, then filtered and finally fed to the analog digital converter. The measuring circuits can be applied in star or delta connection (refer to chapter 4.3.1).

3.1.2 Blocking input

The blocking function can be set according to requirement. By applying the auxiliary voltage to D8/E8, the previously set relay functions are blocked (refer to 4.8 and 5.7.1).

3.1.3 Reset input

Please refer to chapter 5.9.1.

3.1.4 Output relays

The *MRN3* is equipped with 5 output relays. Apart from the relay for self-supervision, all protective functions can be optionally assigned:

- Relay 1: C1, D1, E1 and C2, D2, E2
- Relay 2: C3, D3, E3 and C4, D4, E4
- Relay 3: C5, D5, E5
- Relay 4: C6, D6, E6
- Relay 5: Signal self-supervision (internal failure of the unit) C7, D7, E7

All trip and alarm relays are working current relays, the relay for self supervision is an idle current relay.

3.1.5 Fault recorder

The *MRN3* has a fault value recorder which records the measured analog values as instantaneous values.
The instantaneous values

U_{L1}; U_{L2}; U_{L3} for star connection
or U_{12}; U_{23}; U_{21} for delta connection

are scanned at a raster of 1.25 ms (at 50 Hz) and 1.041 ms (at 60 Hz) and saved in a cyclic buffer. It is possible to store 1 - 8 fault occurences with a total recording time of 16 s (with 50 Hz) and 13.33 s (with 60 Hz) per channel.

Storage division

Independent of the recording time, the entire storage capacity can be divided into several cases of disturbance with a shorter recording time each. In addition, the deletion behaviour of the fault recorder can be influenced.

No writing over

If 2, 4 or 8 recordings are chosen, the complete memory is divided into the relevant number of partial segments. If this max. number of fault event has been exceeded, the fault recorder block any further recordings in order to prevent that the stored data are written over. After the data have been read and deleted, the recorder to ready again for further action.

Writing over

If 1, 3 or 7 recordings are chosen, the relevant number of partial segments is reserved in the complete memory. If the memory is full, a new recording will always write over the oldest one.

The memory part of the fault recorder is designed as circulating storage. In this example 7 fault records can be stored (written over).

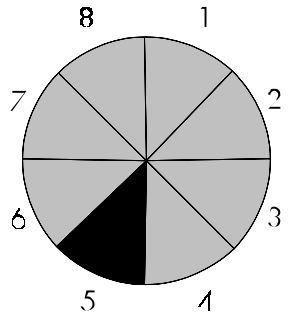

Figure 3.2: Division of the memory into 8 segments, for example

Memory space 6 to 4 is occupied.
Memory space 5 is currently being written in

Since memory spaces 6, 7 and 8 are occupied, this example shows that the memory has been assigned more than eight recordings. This means that No. 6 is the oldest fault recording and No. 4 the most recent one.

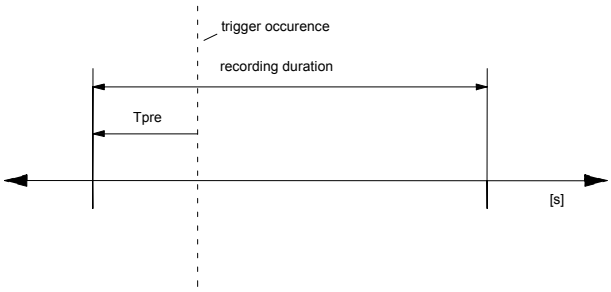

Figure 3.3: Basic set-up of the fault recorder

Each memory segment has a specified storage time which permits setting of a time prior to the trigger event.

Via the interface RS485 the data can be read and processed by means of a PC (HTL/PL-Soft4). The data is graphically edited and displayed. Binary tracks are recorded as well, e.g. activation and trip.

3.2 Parameter settings

Table 3.6: Date and time

The window for parameter setting is located behind the measured value display. The parameter window can be accessed via the <SELECT/RESET> key.

3.3 LEDs

All LEDs (except LED RS, min. and max.) are two-coloured. The LEDs on the left side, next to the alpha-numerical display light up green during measuring and red after tripping.

The LEDs below the push button <SELECT/RESET> are lit green during setting and inquiry procedure of the setting values which are printed on the left side next to the LEDs. The LEDs will light up red after parametrizing of the setting values next to their right side.

The LED marked with letters RS lights up during setting of the slave address of the device for serial data communication.

The LED marked with the letters FR is alight while the fault recorder is being adjusted.

3.4 Front plate

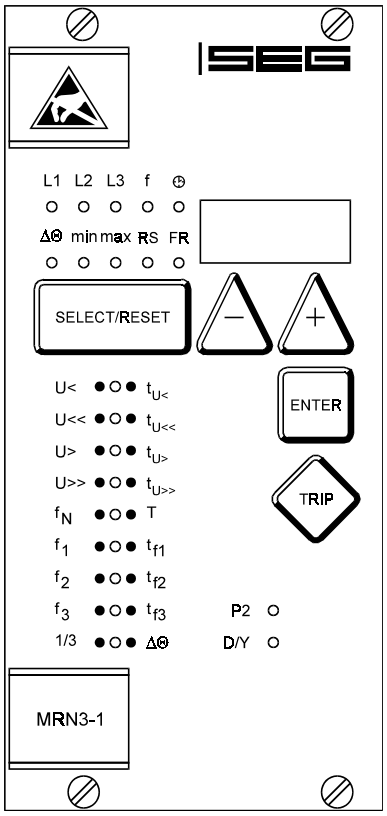

Figure 3.4: Front plate MRN3-1

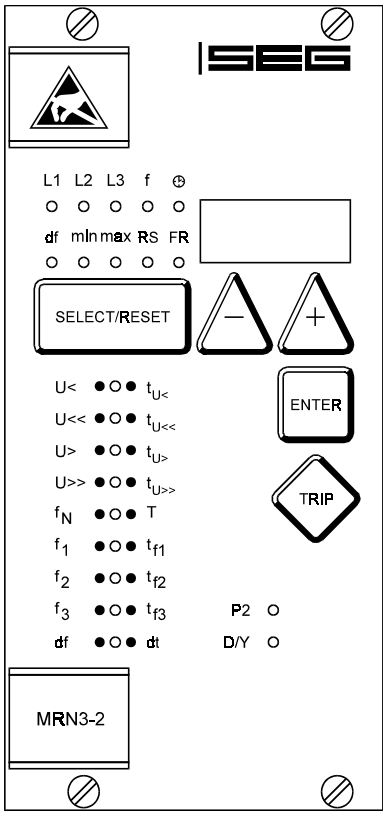

Figure 3.5: Front plate MRN3-2

4 Working principle

4.1 Analog circuits

The input voltages are galvanically insulated by the input transformers. The noise signals caused by inductive and capacitive coupling are supressed by an analog R-C filter circuit.

The analog voltage signals are fed to the A/D-converter of the microprocessor and transformed to digital signals through Sample- and Hold- circuits. The analog signals are sampled with a sampling frequency of 16 x f_N, namely, a sampling rate of 1.25 ms for every measuring quantity, at 50 Hz.

4.2 Digital circuits

The essential part of the *MRN3* relay is a powerful microcontroller. All of the operations, from the analog digital conversion to the relay trip decision, are carried out by the microcontroller digitally. The relay program is located in an EPROM (Electrically-Programmable-Read-Only-Memory). With this program the CPU of the microcontroller calculates the three phase voltage in order to detect a possible fault situation in the protected object.

For the calculation of the voltage value an efficient digital filter based on the Fourier Transformation (DFFT - Discrete Fast Fourier Transformation) is applied to suppress high frequency harmonics and d.c. components caused by fault-induced transients or other system disturbances. The microprocessor continuously compares the measured values with the preset thresholds stored in the parameter memory (EEPROM). If a fault occures an alarm is given and after the set tripping delay has elapsed, the corresponding trip relay is activated.

The relay setting values for all parameters are stored in a parameter memory (EEPROM - Electrically Erasable Programmable Read Only Memory), so that the actual relay settings cannot be lost, even if the power supply is interrupted.
The microprocessor is supervised by a built-in "watchdog" timer. In case of a failure the watchdog timer resets the microprocessor and gives an alarm signal via the output relay "self supervision".

4.3 Voltage supervision

The voltage element of *MRN3* has the application in protection of generators, consumers and other electrical equipment against over-/and undervoltage.
The relay is equipped with a two step independent three-phase overvoltage (U>, U>>) and undervoltage (U<, U<<) function with completely separate time and voltage settings.
In delta connection the phase-to-phase voltages and in star connection the phase-to-neutral voltages are continuously compared with the preset thresholds.

For the overvoltage supervision the highest, for the undervoltage supervision of the lowest voltage of the three phases are decisive for energizing.

4.3.1 Selection of star or delta connection

All connections of the input voltage transformers are led to screw terminals. The nominal voltage of the device is equal to the nominal voltage of the input transformers. Dependent on the application the input transformers can be connected in either delta or star. The connection for the phase-to-phase voltage is the delta connection. In star connection the measuring voltage is reduced by $1/\sqrt{3}$. During parameter setting the connection configuration either Y or Δ has to be adjusted.

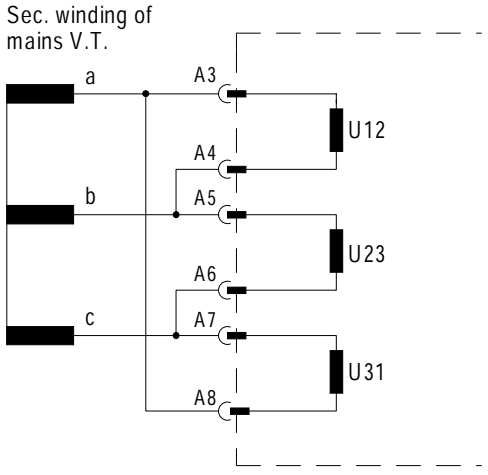

Figure 4.1: Input v.t.s in delta connection (Δ)

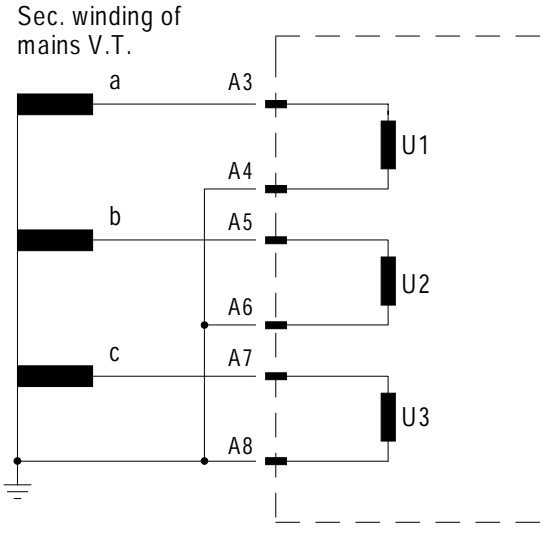

Figure 4.2: Input v.t.s in star connection (Y)

4.4 Principle of frequency supervision

The frequency element of *MRN3* protects electrical generators, consumers or electrical operating equipment in general against over- or underfrequency.
The relay has independent three frequency elements f_1 - f_3 with a free choice of parameters, with separate adjustable pickup values and delay times.

The measuring principle of the frequency supervision is based in general on the time measurement of complete cycles, whereby a new measurement is started at each voltage zero passage. The influence of harmonics on the measuring result is thus minimized.

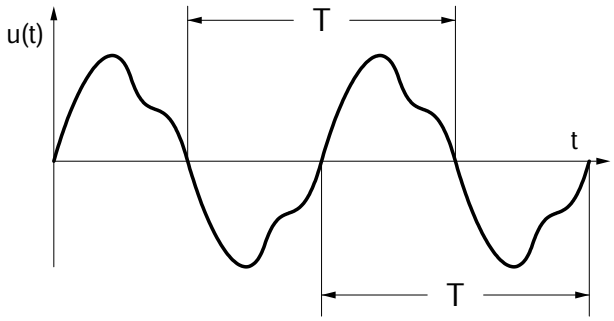

Figure 4.3: Determination of cycle duration by means of zero passages.

In order to avoid false tripping during occurence of interference voltages and phase shifts the relay works with an adjustable measuring repetition. (refer to chapter 5.4.2)

Frequency tripping is sometimes not desired by low measured voltages which for instance occur during alternator acceleration. All frequency supervision functions can be blocked with the aid of an adjustable voltage threshold U_B in case the measured voltages value is below this value.

4.5 Measuring of frequency gradient (*MRN3-2*)

Electrical generators running in parallel with the mains, e.g. industrial internal power supply plants, should be separated from the mains when failure in the intrasystem occurs for the following reasons:

- It must be prevented that the electrical generators are damaged when mains voltage recovering asynchrone, e.g. after a short interruption.
- The industrial internal power supply must be maintained.

A reliable criterion of detecting mains failure is the measurement of the rate of change of frequency df/dt. Precondition for this is a load flow via the mains coupling point. At mains failure the load flow changing then spontaneously leads to an increasing or decreasing frequency. At active power deficit of the internal power station a linear drop of the frequency occurs and a linear increase occurs at power excess. Typical frequency gradients during application of "mains decoupling" are in the range of 0.5 Hz/s up to over 2 Hz/s. The *MRN3* detects the instantaneous frequency gradient df/dt of each mains voltage period in an interval of one half period each. Through multiple evaluation of the frequency gradient in sequence the continuity of the directional change (sign of the frequency gradient) is determined. Because of this special measuring procedure a high safety in tripping and thus a high stabilty against transient processes, e.g. switching procedure are reached. The total switching off time at mains failure is between 60 ms and 80 ms depending on the setting.

4.6 Vector surge supervision (*MRN3-1*)

The vector surge supervision protects synchronous generators in mains parallel operation due to very fast decoupling in case of mains failure. Very dangerous are mains auto reclosings for synchronous generators. The mains voltage returning after 300 ms can hit the generator in asynchronous position. A very fast decoupling is also necessary in case of long time mains failures. Generally there are two different applications:

a) Only mains parallel operation no single operation:
In this application the vector surge supervision protects the generator by tripping the generator circuit breaker in case of mains failure.

b) Mains parallel operation and single operation:
For this application the vector surge supervision trips the mains circuit breaker. Here it is insured that the gen.-set is not blocked when it is required as the emergency set.

A very fast decoupling in case of mains failures for synchronous generators is known as very difficult. Voltage supervision units cannot be used because the synchronous alternator as well as the consumer impedance support the decreasing voltage.

For this the mains voltage drops only after some 100 ms below the pickup threshold of voltage supervision relays and therefore a safe detection of mains auto reclosings is not possible with this kind of relay.

Frequency relays are partial unsuitable because only a highly loaded generator decreases its speed within 100 ms. Current relays detect a fault only when short-circuit type currents exist, but cannot avoid their development. Power relays are able to pickup within 200 ms, but they cannot prevent power to rise to short-circuit values too. Since power changes are also caused by sudden loaded alternators, the use of power relays can be problematic.

Whereas the *MRN3-1* detects mains failures within 60 ms without the restrictions described above because they are specially designed for applications where very fast decoupling from the mains is required.

Adding the operating time of a circuit breaker or contactor, the total disconnection time remains below 150 ms. Basic requirement for tripping of the generator/mains monitor is a change in load of more than 15 - 20% of the rated load. Slow changes of the system frequency, for instance at regulating processes (adjustment of speed regulator) do not cause the relay to trip.

Trippings can also be caused by short-circuits within the grid, because a voltage vector surge higher than the preset value can occur. The magnitude of the voltage vector surge depends on the distance between the short-circuit and the generator. This function is also of advantage to the Power Utility Company because the mains short-circuit capacity and consequently the energy feeding the short-circuit is limited.

To prevent a possible false tripping the vector surge measuring can be blocked at a set low input voltage (refer to 5.4.7). The undervoltage lockout acts faster then the vector surge measurement.

Vector surge tripping is blocked by a phase loss so that a VT fault (e.g. faulty VTs fuse) does not cause false tripping.
When switching on the aux. voltage or measuring voltage , the vector surge supervision is blocked for 5 s (refer to chapter 4.8).

Note:
In order to avoid any adverse interference voltage effects, for instance from contactors or relays, which may cause overfunctions, *MRN3-1* should be connected separately to the busbar.

4.6.1 Measuring principle of vector surge supervision

When a synchronous generator is loaded, a rotor displacement angle is build between the terminal voltage (mains voltage U1) and the synchronous internal voltage (Up). Therefore a voltage is difference ΔU is built between Up and U1 (Fig. 4.4).

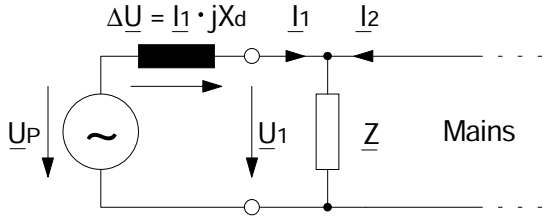

Figure 4.4: Equivalent circuit at synchronous generator in parallel with the mains

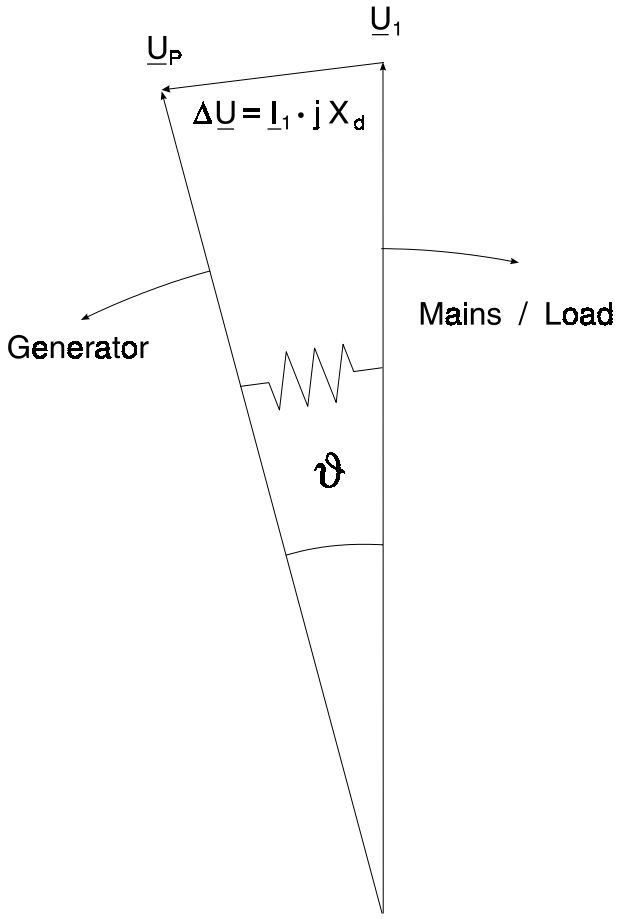

Figure 4.5: Voltage vectors at mains parallel operation

The rotor displacement angle ϑ between stator and rotor is depending of the mechanical moving torque of the generator shaft. The mechanical shaft power is balanced with the electrical feeded mains power, and therefore the synchronous speed keeps constant (Fig. 4.5).

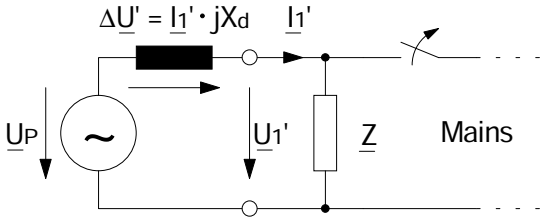

Figure 4.6: Equivalent circuit at mains failure

In case of mains failure or auto reclosing the generator suddenly feeds a very high consumer load. The rotor displacement angle is decreased repeatedly and the voltage vector $\underline{U}_1$ changes its direction ($\underline{U}_1$') (Fig. 4.6 and 4.7).

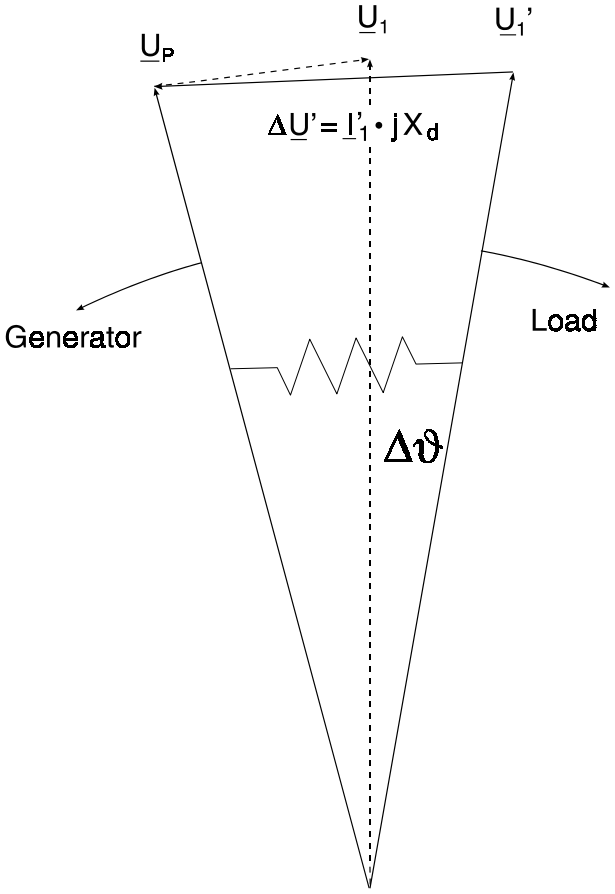

Figure 4.7: Voltage vectors at mains failure

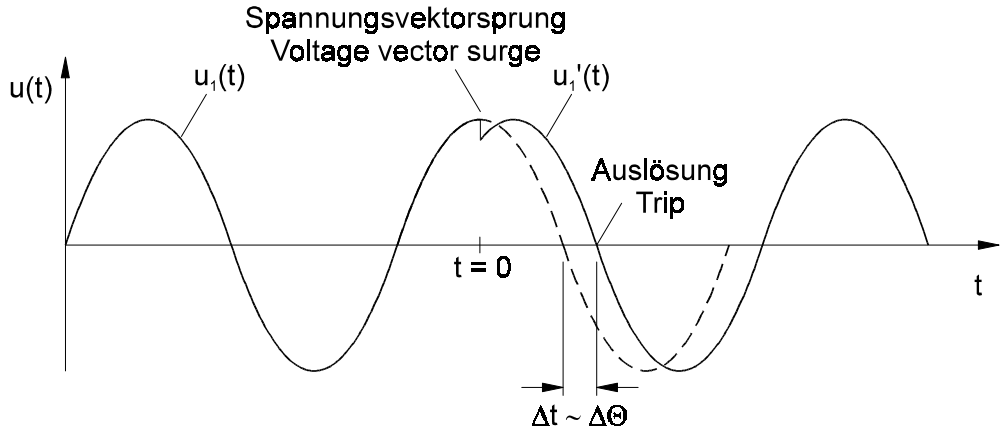

Figure 4.8: Voltage vector surge

As shown in the voltage/time diagram the instantaneous value of the voltage jumps to another value and the phase position changes. This is named phase or vector surge.

The *MRN3-1* measures the cycle duration. A new measuring is started at each voltage zero passage. The measured cycle duration is internally compared with a quartz stable reference time and from this the deviation of the cycle duration of the voltage signal is ascertained. In case of a vector surge as shown in fig. 4.8, the zero passage occurs either earlier or later. The established deviation of the cycle duration is in compliance with the vector surge angle.
If the vector surge angle exceeds the set value, the relay trips immediately.

Tripping of the vector surge is blocked in case of loss of one or more phases of the measuring voltage.

Tripping logic for vector surge measurement:

The vector surge function of the *MRN3-1* supervises vector surges in all three phases at the same time. Tripping of the relay can be adjusted for an one phase vector surge (more sensitive measurement). For this the parameter 1/3 has to be set to "1Ph". When the parameter 1/3 is set to "3Ph", tripping of the vector surge element occurs only if the vector surge angle exceeds the set value in all three phases at the same time.

Application hint

Although the vector surge relay guarantees very fast and reliable detection of mains failures under nearly all operational conditions of mains parallel running alternators, the following borderline cases have to be considered accordingly:

a) None or only insignificant change of power flow at the utility connection point during mains failures.

This can occure during peak lopping operation or in CHP stations (Combined Heat and Power) where the power flow between power station and the public grid may be very low. For detection of a vector surge at parallel running alternators, the load change must be at least 15 - 20% of the rated power. If the active load at the utility connection point is regulated to a minimal value and a high resistance mains failure occurs, then there are no vector surge nor power and frequency changes and the mains failure is not detected.

This can only happen if the public grid is disconnected near the power station and so the alternators are not additionally loaded by any consumers. At distant mains failures the synchronous alternators are abruptly loaded by remaining consumers which leads directly to a vector surge and so mains failure detection is guaranteed.
If such a situation occurs the following has to be taken into account:

In case of an undetected mains failure, i.e. with the mains coupling C.B. closed, the vector surge relay reacts upon the first load change causing a vector surge and trips the mains C.B.

For detecting high resistance mains failures a minimum current relay with an adjustable trip delay can be used. A trip delay is needed to allow regulating actions where the current may reach "zero" at the utility connection point. At high resistance mains failures, the mains coupling C.B. is tripped by the minimum current relay after the time delay.

To prevent asynchronous switching on, an automatic reclosing of the public grid should be not possible during this time delay.

A further measure could be, that the load regulation at the utility connection point guarantees a minimum power flow of 15 - 20% of rated power.

b) Short circuit type loading of the alternators at distant mains failures

At any distant mains failure, the remaining consumers cause sudden short circuit type loading of the power station generators. The vector surge relay detects the mains failure in about 60 ms and switches off the mains coupling C.B. The total switch off time is about 100 - 150 ms. If the generators are provided with an extremely fast short circuit protection e.g. able to detect di/dt, the alternators might be switched off unselectively by the generator C.B., which is not desireable because the power supply for the station is endangered and later on synchronized changeover to the mains is only possible after manual reset of the overcurrent protection.

To avoid such a situation, the alternator C.B.s must have a delayed short circuit protection. The time delay must be long enough so that mains decoupling by the vector surge relay is guaranteed.

4.7 Voltage threshold value for frequency measuring

At low measuring voltages, e.g. during generator start-up, frequency and vector surge or df/dt-measuring is perhaps not desired.

By means of the adjustable voltage threshold value $U_B<$, functions f_1 - f_3, df/dt or $\Delta\Theta$ are blocked if the measured voltage falls below the set value.

4.8 Blocking function

No.	Dynamic Behaviour	U</<<	U>/>>	f_1, f_2, f_3	$\Delta\Theta$	df/dt
1	voltage to external blocking input is applied	free programmable	free programmable	free programmable	free programmable	free programmable
2	blocking input is released	released instantaneously	released instantaneously	released after 1 s	released after 5 s	released after 5 s
3	supply voltage is switched on	blocked for 200 ms	blocked for 200 ms	blocked for 1 s	blocked for 1 s	blocked for 1 s
4	3ph measuring volt. is suddenly applied	released	released	blocked for 1 s	blocked for 5 s	blocked for 5 s
5	one or several measuring voltages are switched off suddenly (phase failure)	released	released	blocked	blocked	blocked
6	measuring voltage smaller $U_B<$ (adjustable voltage threshold value)	released	released	blocked	blocked	blocked

*Table 4.1: Dynamic behaviour of **MRN3** functions*

Blocking function set in compliance with requirements:

The *MRN3* has an external blocking input. By applying the auxiliary voltage to input D8/E8, the requested protection functions of the relay are blocked (refer to 5.7.1).

5 Operation and setting

Table 5.1: Possible indication messages on the display

5.2 Setting procedure

In this paragraph the settings for all relay parameters are described in detail. For parameter setting a password has to be entered first (please refer to 4.4 of description "*MR*-Digital Multifunctional Relays").

5.3 Systemparameter

5.3.1 Display of residual voltage U_E as primary quantity (U_{prim}/U_{sec})

The residual voltage can be shown as primary measuring value. For this parameter the transformation ratio of the VT has to be set accordingly. If the parameter is set to "sek", the measuring value is shown as rated secondary voltage.

Example:
The voltage transformer used is of 10 kV/100 V. The transformation ratio is 100 and this value has to be set accordingly. If still the rated secondary voltage should be shown, the parameter is to be set to 1.

5.3.2 Δ/Y – Switch over

Depending on the mains voltage conditions, the input voltage transformers can be operated in delta or Y connection. Change-overs are effected via the <+> and the <-> keys and stored with <ENTER>.

5.3.3 Setting of nominal frequency

For proper functioning it is necessary to first adjust the rated frequency (50 oder 60 Hz).

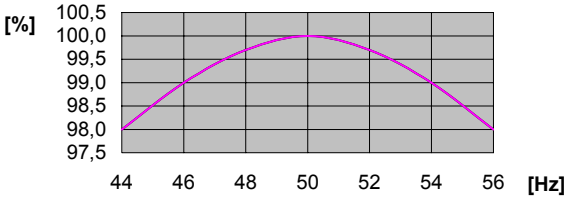
For this a distinction has to be made between the settings v = 50 Hz / f = 50 Hz or v = 60 Hz / f = 60 Hz
The difference lies in the method of voltage measuring. With the setting "v" = 50/60 Hz voltage measuring is independent of the existing frequency. This means, the voltage value can be correctly measured between 30 Hz and 80 Hz without adverse effects from the frequency.

With the setting "f" = 50/60 Hz the measured voltage value is influenced by the frequency. (see Table 5.2)

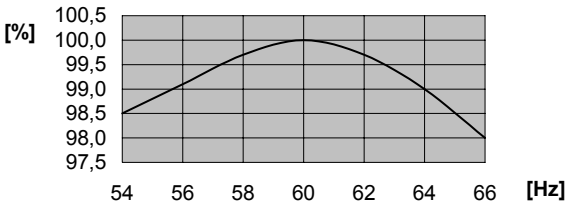
This difference in settings is required for the fault recorder. If the fault recorder is to be used, the setting must be f = 50 Hz or f = 60 Hz.
The different designations "f" or "v" have no influence on any of the other functions.

All frequency functions are determined by setting the nominal frequency, i.e. whether the set frequency thresholds are evaluated as over- or underfrequency (see also chapter 5.4.4). Also the cycle duration (20 ms at 50 Hz and 16.67 ms at 60 Hz) derives from this setting which determines the minimum tripping delay for frequency elements f_1 - f_3 with an adjustable multiplier (see also chapter 5.4.5).
During setting of the nominal frequency a value in Hz is shown on the display.

Declination of measuring value at 50Hz



Declination of measuring value at 60Hz



Setting	v = 50	f = 50	v = 60	f = 60
Rated frequency	50 Hz	50 Hz	60 Hz	60 Hz
Influence on voltage measurement	none	0.5..1%/Hz (see table 5.2)	none	0.5..1%/Hz (see table 5.2)
Fault recorder	Recording distorted**	Recording correct***	Recording distorted**	Recording correct***
Influence on all other functions	none	none	none	none

Table 5.2: Deviation of measured value at 50 or 60 Hz

* Setting is important for differentiation between over- and underfrequency
** Sample rate is variably adjusted to the momentarily measured frequency. 16 samples are always measured in one period.
*** Sample rate setting is fixed to 50 Hz or 60 Hz. 16 samples per 20 ms or 16.67 ms are always measured.

5.3.4 Display of the activation storage (FLSH/NOFL)

If after an activation the existing current drops again below the pickup value, e.g. U<, without a trip has been initiated, LED U< signals that an activation has occured by flashing fast. The LED keeps flashing until it is reset again (push button <RESET>). Flashing can be suppressed when the parameter is set to NOFL.

5.3.5 Parameterswitch/external trigger for the fault recorder

By means of the parameter-change-over switches it is possible to activate two different parameter sets. Switching over of the parameter sets can either be done by means of software or via the external inputs RESET or blocking input. Alternatively, the external inputs can be used for Reset or blocking and for the triggering of the fault recorder.

Software-parameter	Blocking input used as	RESET input used as
SET1	Blocking input	RESET input
SET2	Blocking input	RESET input
B_S2	Parameter switch	RESET input
R_S2	Blocking input	Parameter switch
B_FR	External triggering of the fault recorder	Reset input
R_FR	Blocking input	External triggerung of the fault recorder
S2_FR	Parameter switch	External triggerung of the fault recorder

With the settings SET1 or SET2 the parameter set is activated by software. Terminals C8/D8 and D8/E8 are then available as external reset input or blocking input.

With the setting B_S2 the blocking input (D8, E8) is used as parameter-set change-over switch. With the setting R_S2 the reset input (D8, E8) is used as parameter-set change-over switch. With the setting B_FR the fault recorder is activated immediately by using the blocking input. On the front plate the LED FR will then light up for the duration of the recording. With the setting R_FR the fault recorder is activated via the reset input. With the setting S2_FR parameter set 2 can be activated via the blocking input and/or the fault recorder via the reset input. The relevant function is then activated by applying the auxiliary voltage to one of the external inputs.

With the setting R_FR the fault recorder is activated via the reset input. With the setting S2_FR parameter set 2 can be activated via the blocking input and/or the fault recorder via the reset input.
The relevant function is then activated by applying the auxiliary voltage to one of the external inputs.

Important note:
When functioning as parameter change over facility, the external input RESET is not available for resetting. When using the external input BLOCKING the protection functions must be deactivated by software blocking separately (refer to chapter 5.7.1).

5.4 Protection parameters

5.4.1 Parameter setting of over- and undervoltage supervision

The setting procedure is guided by two coloured LEDs. During setting of the voltage thresholds the LEDs U<, U<<, U> and U>> are lit green. During setting of the trip delays $t_{U>}$, $t_{U>>}$, $t_{U<}$ and $t_{U<<}$ the according LEDs light up red.

Thresholds of the voltage supervision

During setting of the threshold U>, U>>, U< and U<< the displays shows the voltages directly in volt. The thresholds can be changed by the <+> <-> push buttons and stored with <ENTER>.

The undervoltage supervision (U< and U<<) as well as the overvoltage supervision (U> and U>>) can be deactivated by setting the threshold to "EXIT".

Tripping delay of voltage supervision

During setting of the tripping delays $t_{U<}$, $t_{U<<}$, $t_{U>}$ and $t_{U>>}$ the display shows the value directly in seconds. The tripping delay is changed via the push button <+> and <-> in the range of 0,04 s to 50 s and can be stored with the push button <ENTER>.
When setting the tripping delay to "EXIT" the value is infinit meaning only warning, no tripping.

5.4.2 Number of measuring repetitions (T) for frequency functions

In order to avoid false tripping of the unit at short voltage drops of the system voltage or interference voltages, *MRN3* works with an adjustable measuring repetition. When the instantaneous frequency measuring value exceeds (at overfrequency) or falls below (at underfrequency) the set reference value, the counter is incremented, otherwise the counter is decremented down to the minimum value of 0. Only when the counter exceeds the value adjusted at T, alarm is given and after the tripping delay of the frequency element has elapsed the tripping command is given.
The setting range for T is between 2 - 99.

Recommendation for setting:
For short tripping times, e.g. for machine protection or for mains decoupling T should be set in the range from 2 - 5.
At precision measurements, e.g. exact measurement of the system frequency a setting of T in the range from 5 - 10 is recommended.

5.4.3 Threshold of frequency supervision

The frequency supervision of *MRN3* has three frequency elements independent from each other. Acc. to setting the pickup value above or below the nominal frequency, these elements can be used for over- or under frequency supervision.

Dependent on the preset nominal frequency f_N the pickup values from 30 Hz up to 70 Hz at f_N = 50 Hz and from 40 Hz to 80 Hz at f_N = 60 Hz can be set. During setting of the pickup values f_1 - f_3 the display shows the values in Hz. A value of for instance 49,8 Hz is indicated with "4980".

The function of the individual frequency elements can be deactivated by setting the pickup values to "EXIT". The setting value "EXIT" corresponds to the rated frequency.

5.4.4 Tripping delays for the frequency elements

Tripping delays t_{f1} - t_{f3} of the four frequency elements can be set independently from $t_{f1\,min}$ - 50 s. The minimum tripping delay $t_{f1\,min}$ of the relay depends upon the number of set measuring repetitions T (periods) and amounts to:

T	$t_{f\,min}$
2....49	(T+1)·20 ms
50....69	(T - 49)·50 ms + 1 s
70....99	(T - 69)·100 ms + 2 s

When setting the tripping delay to "EXIT" by pressing push button <+> up to the maximum setting value, the corresponding tripping relay is blocked. Pickup of the frequency element is however displayed on the front plate by the corresponding LED, an assigned alarm relay is also activated. This setting applies to 50 Hz and 60 Hz.

5.4.5 Parameter setting of vector surge supervision (*MRN3-1*)

Both the vector surge angle ΔΘ as well as the tripping logic concerning the vector surge have to be adjusted for a vector surge supervision.
If the tripping logic is set to 1-of-3 (= "1Ph" on the display), the relay trips as soon as the measured vector surge angle has exceeded the set value ΔΘ in one of the three phases. This is the more sensitive adjustment when compared with the three phase tripping logic 3-of-3 (= "3Ph" on the display), where tripping occurs only if the vector surge angle exceeds the set value in all three phases.

We recommend to choose the one phase tripping logic "1Ph". Only if this adjustment is too sensitive, adjustment "3Ph" should be used.

The recommended setting of the vector surge angle ΔΘ in a low impedance mains is 4 - 6 degrees. This setting is sufficient in most cases, because low impedance mains do not have a vector surge greater than this value. In case of an auto reclosing, this value is exceeded. In high impedance mains the setting should be 10° to 12° to avoid failure tripping when switching on or switching off big consumer loads.

The vector surge function of this device can be checked as follows:

a) Generator in isolated operation: Switching off and on of loads (approx. 20% of the nominal generator capacity) must trip the relay. Later in normal isolated operation the tripping of the relay is inhibited.

b) In mains parallel operation switching on and switching off of consumer loads and controlling the governor of the prime mover should not trip the relay.

If possible the test described under a) and b) should be double checked by a real auto reclosing.

Threshold for the vector surge supervision

When the pickup value of the vector surge supervision is set, a value in angular degree is indicated at the display. The pickup value requested can be adjusted by pushbuttons <+> and <-> in the range of 2° to 22°. LED ΔΘ lights up red during this procedure.

5.4.6 Parameter setting of frequency gradient (*MRN3-2*)

The pickup value of frequency gradient (parameter df) can be set between 0.2 to 10 Hz/s. The number of measuring repetitions (parameter dt) can be set between 2 - 64 cycles. This parameter defines the number of df/dt measurements, which have to exceed the set value, before tripping.

Setting information:
The power difference after mains failure causes a change in frequency, which can approximately be calculated as follows:

$$\frac{df}{dt} = -\frac{f_N}{T_A} \cdot \Delta P$$

with
f_N = rated frequency in Hz
T_A = starting time at rated torque
ΔP = per unit power deficit with reference to the rated active power of the generator

If the inertia time constant is known and a power difference given, the frequency gradient can be estimated by the a.m. equation. At a supposed power difference of 20% and an inertia time constant of 10 s, the frequency gradient is 1 Hz/s.

To prevent false trippings at loading, deloading or failure signals, we would recommend a setting value for dt of minimum 4 cycles.

5.4.7 Voltage threshold value for frequency and vector surge measuring (df/dt at *MRN3-2*)

Correct frequency measuring or vector surge measuring cannot be obtained if the system voltage is very low, for instance during generator start up or voltage failure. False tripping of the *MRN3* in such cases is prevented by an adjustable voltage threshold U_B. If the system voltage is below this threshold, these functions of the relay are blocked.
During adjustment of U_B< LEDs f and ΔΘ or df light up in the upper display part.

5.4.8 Adjustment of the slave address

By pressing push buttons <+> and <-> the slave address can be set in the range of 1 - 32. During this adjustment the LED RS lights up.

5.4.9 Setting of Baud-rate (applies for Modbus Protocol only)

Different transmission rates (Baud rate) can be set for data transmission via Modbus Protocol.
The rate can be changed by push buttons <+> and <-> and saved by pressing <ENTER>.

5.4.10 Setting of parity (applies for Modbus Protocol only)

The following three parity settings are possible :

- "even" = even
- "odd" = odd
- "no" = no parity check

The setting can be changed by push buttons <+> and <-> and saved by pressing <ENTER>.

5.5 Adjustment of the fault recorder

The *MRI3* is equipped with a fault recorder (see chapter 3.7). Three parameters can be determined.

5.5.1 Number of the fault recordings

The max. recording time is 16 s at 50 Hz or 13.33 s at 60 Hz.
The number of max. recordings requested has to be determined in advance. There is a choice of (1)* 2, (3)* 4 or (7)* 8 recordings and dependent on this the duration of the individual fault recordings is defined, i.e.

(1)* 2 recordings for a duration of 8 s (with 50 Hz) (6.66 s with 60 Hz)
(3)* 4 recordings for a duration of 4 s (with 50 Hz) (3.33 s with 60 Hz)
(7)* 8 recordings for a duration of 2 s (with 50 Hz) (1,66 s with 60 Hz)
* is written over when a new trigger signal arrives

Caution:
If the fault recorder is used, the frequency should be set to f = 50 Hz or f = 60 Hz (see chapter 5.3.3).

5.5.2 Adjustment of trigger occurences

There is a choice between four different occurences:

P_UP (PickUP)	Storage is initiated after recognition of a general activation.
TRIP	Storage is initiated after a trip has occured.
A_PI (After Pickup)	Storage is initiated after the last activation threshold was fallen short of.
TEST	Storing is activated by simultaneous actuation of the keys <+> and <->. During the recording time the display shows "Test".

5.5.3 Pre-trigger time (T_{pre})

By the time T_{pre} it is determined which period of time prior to the trigger occurence should be stored as well. It is possible to adjust a time between 0.05s and the max. recording interval (2, 4 and 8s). With keys <+> and <-> the values can be changed and with <ENTER> be saved.

5.6 Adjustment of the clock

When adjusting the date and time, LED ◷ lights up.
The adjustment method is as follows:

Date :	Year	Y=00
	Month	M=00
	Day	D=00
Time :	Hour	h=00
	Minute	m=00
	Second	s=00

The clock starts with the set date and time as soon as the supply voltage is switched on. The time is safeguarded against short-term voltage failures (min. 6 minutes).

Note:
The window for parameter setting is located behind the measured value display. The parameter window can be accessed via the <SELECT/RESET> key.

5.7 Additional functions

5.7.1 Setting procedure for blocking the protection functions

The blocking function of the *MRN3* can be set according to requirement. By applying the aux. voltage to D8/E8, the functions chosen by the user are blocked. Setting of the parameter should be done as follows:

- When pressing push buttons <ENTER> and <TRIP> at the same time, message "BLOC" is displayed (i.e. the respective function is blocked) or "NO_B" (i.e. the respective function is not blocked). The LED allocated to the first protection function U< lights red.
- By pressing push buttons <+> <-> the value displayed can be changed.
- The changed value is stored by pressing <ENTER> and entering the password.
- By pressing the <SELECT/RESET> push button, any further protection function which can be blocked is displayed.
- Thereafter the menu is left by pressing <SELECT/RESET> again.
- If the <SELECT/RESET> key is actuated again, the blocking menu is left and the assignment mode is accessed^.

Function	Description	Display	LED
U<	Undervoltage step 1	BLOC	red
U<<	Undervoltage step 2	BLOC	red
U>	Overvoltage step 1	NO_B	red
U>>	Overvoltage step 2	NO_B	red
f1	Frequency step 1	BLOC	red
f2	Frequency step 2	BLOC	rec
f3	Frequenzstufe 3	NO_B	red
ΔΘ	Vector surge	BLOC	red
df/dt	Frequency changing rate	BLOC	red

Table 5.3: Blockadefunktion für twei Parametersätze

Assignment of the output relays:
Unit *MRN3* has five output relays. The fifth output relay is provided as permanent alarm relay for self supervision is normally on. Output relays 1 - 4 are normally off and can be assigned as alarm or tripping relays to the voltage functions which can either be done by using the push buttons on the front plate or via serial interface RS485. The assignment of the output relays is similar to the setting of parameters, however, only in the assignment mode. The assignment mode can be reached only via the blocking mode.
By pressing push button <SELECT/RESET> in blocking mode again, the assignment mode is selected.

The relays are assigned as follows: LEDs U<, U<<, U> and U>>, f1, f2, f3 are two-coloured and light up green when the output relays are assigned as alarm relays and $t_{U<}$, $t_{U<<}$, $t_{U<}$, $t_{U<<}$, tf1, tf2, tf3 df/dt and ΔΘ red as tripping relays.

Definition:
Alarm relays are activated at pickup.
Tripping relays are only activated after elapse of the tripping delay.

After the assignment mode has been activated, first LED U< lights up green. Now one or several of the four output relays can be assigned to under voltage element U< as alarm relays. At the same time the selected alarm relays for under voltage element 1 are indicated on the display. Indication "1_ _ _" means that output relay 1 is assigned to this under voltage element. When the display shows "_ _ _ _", no alarm relay is assigned to this under voltage element. The assignment of output relays 1 - 4 to the current elements can be changed by pressing <+> and <-> push buttons. The selected assignment can be stored by pressing push button <ENTER> and subsequent input of the password. By pressing push button <SELECT/RESET>, LED U< lights up red. The output relays can now be assigned to this voltage element as tripping relays.

Relays 1 - 4 are selected in the same way as described before. By repeatedly pressing of the <SELECT/RESET> push button and assignment of the relays all elements can be assigned separately to the relays. The assignment mode can be terminated at any time by pressing the <SELECT/RESET> push button for some time (abt. 3 s).

Note:
- The function of jumper J2 described in general description "MR Digital Multifunctional Relays" does not apply for *MRN3*. For relays without assignment mode this jumper is used for parameter setting of alarm relays (activation at pickup or tripping).

A form is attached to this description where the setting requested by the customer can be filled-in. This form is prepared for telefax transmission and can be used for your own reference as well as for telephone queries.

Relay function		Output relays				Display-	Corresponding
		1	2	3	4	Indication	LED
U<	alarm		X			_ 2 _ _	U<; green
tU<	tripping	X				1 _ _ _	tU< red
U<<	alarm		X			_ 2 _ _	U<< green
tU<<	tripping	X				1 _ _ _	tU<< red
U>	alarm		X			_ 2 _ _	U> green
tU>	tripping	X				1 _ _ _	tU> red
U>>	alarm		X			_ 2 _ _	U>> green
tU>>	tripping	X				1 _ _ _	tU>> red
f1	alarm			X		_ _ 3 _	f1 green
tf1	tripping	X				1 _ _ _	tf1 red
f2	alarm			X		_ _ 3 _	f2 green
tf2	tripping	X				1 _ _ _	tf2 red
f3	alarm			X		_ _ 3 _	f3 green
tf3	tripping	X				1 _ _ _	tf3 red
$\Delta\Theta$	tripping				X	_ _ _ 4	$\Delta\Theta$ red
df/dt	tripping				X	_ _ _ 4	df/dt red

Tabelle 5.4: Example of assignment matrix of the output relay (default settings).

5.8 Indication of measuring values

5.8.1 Measuring indication

In normal operation the following measuring values can be displayed.

Voltages (LED L1, L2, L3 green)
- In star connection all phase-to-neutral voltages
- In delta connection all phase-to-phase voltages

Frequency (LED f green *MRN3-1*)
Vector surge (LED $\Delta\Theta$ green)
Frequency gradient df/dt (LED df green; *MRN3-2*)

Min. and max. values prior to the last reset:
- Frequency (LED f + min or f + max)
- Vector surge (LED $\Delta\Theta$ + min or $\Delta\Theta$ + max)
- Frequency gradient (LED df + min or df + max)

5.8.2 Min./Max.- values

The *MRN3* offers a minimum/maximum storage each for the measuring values of the vector surge as well as the frequency gradient. These min./max. values are mainly used to appraise the system quality. Always the highest and lowest values of each cycle are measured and stored until the next reset.

Min./max. frequency measuring:
The *MRN3* ascertains the actual frequency from each cycle of the system voltage. These measuring values are entered into the min./max. storage. The latest entered min./max. values replace the previously stored values.

Dependent on the adjustment of dt and tripping delay, it is possible that the stored min./max. values are higher than the tripping threshold without causing a trip. The reason for this is storage of instantaneous values.

Min./Max. measuring of the frequency gradient:
The procedure described above applies also to storage of min./max. values of df/dt measurement. Since each instantaneous df/dt value is stored, high values can occur which, however, do not cause any tripping.

This can for instance happen during switching procedures where high positive and negative df/dt values occur, but they do not cause any tripping due to the special measuring method.

Min./max. vector surge measuring :
The procedure described above applies also to storage of min./max. values of vector surge measuring. Since each instantaneous $\Delta\Theta$ value is stored, also here high values are possible which, however, do not cause any tripping.

These min./max. measurements are of great advantage for long-time analysis of the grid quality.

As to operation :
After each reset (ref. 5.9.1) the min./max. storages are cleared. As from this instant there is no time limit for the min./max. storage until the next reset.
By repeatedly pressing the <SELECT/RESET> push button, the measuring values of the min./max. storage can be queried. The respective LEDs light up at the same time; e.g. during minimum frequency is displayed, LEDs "f" and "min" light up.

5.8.3 Unit of the measuring values displayed

The measuring values can optionally be shown in the display as a multiple of the "sec" rated value (x In) or as primary current (A). According to this the units of the display change as follows:

Indication as	Range	Unit
sec. voltage	000V – 999V	V
primary voltage	.000 – 999V	V
	1K00 – 9K99	KV
	10K0 – 99K9	KV
	100K – 999K	KV
	1M00 – 3M00	MV

Table 5.5: Units of the display

5.8.4 Indication of fault data

All faults detected by the relay are indicated on the front plate optically. For this purpose, the four LEDs (L1, L2, L3, f) and the four function LEDs (U<, U<<, U>, U>>, f1, f2, f3, $\Delta\Theta$ und df/dt) are equipped at *MRN3*. Not only fault messages are transmitted, the display also indicates the tripped protection function. If, for example an overcurrent occurs, first the respective phase LED will light up. LED I> lights up at the same time. After tripping the LEDs are lit permanently.

5.9 Fault memory

When the relay is energized or is energized or trips, all fault data and times are stored in a non-volatile memory manner. The *MRN3* is provided with a fault value recorder for max. five fault occurrences. In the event of additional trippings always the oldest data set is written over.

For fault indication not only the trip values are recorded but also the status of LEDs. Fault values are indicated when push buttons <-> or <+> are pressed during normal measuring value indication.

- Normal measuring values are selected by pressing the <SELECT/RESET> button.
- When then the <-> button is pressed, the latest fault data set is shown. By repeated pressing the <-> button the last but one fault data set is shown etc. For indication of fault data sets abbreviations FLT1, FLT2, FLT3, ... are displayed (FLT1 means the latest fault data set recorded). At the same time the parameter set active at the occurence is shown.
- By pressing <SELECT/RESET> the fault measuring values can be scrolled.
- By pressing <+> it can be scrolled back to a more recent fault data set. At first FLT8, FLT7, ... are always displayed.When fault recording is indicated (FLT1 etc), the LEDs flash in compliance with the stored trip information, i.e. those LEDs which showed a continuous light when the fault occured are now blinking blinking to indicate that it is not a current fault. LEDs which were blinking blinking during trip conditions, (element had picked up) just briefly flash.
- If the relay is still in trip condition and not yet reset (TRIP is still displayed), no measuring values can be shown.
- To delete the trip store, the push button combination <SELECT/RESET> and <->, has to be pressed for about 3s. The display shows "wait".

Recorded fault data:

Measuring	Displayed value	Corresponding LED
Voltage	L1; L2; L3; L1/L2; L2/L3; L3/L1	L1; L2; L3
Frequency	f; f min f max	f; min; max
Frequency changing rate	df	df
Vektorsprung	$\Delta\Theta$	$\Delta\Theta$
Time stamp		
Date:	Y = 99	🕒
	M = 03	🕒
	D = 10	🕒
Time:	h = 17	🕒
	m = 21	🕒
	s = 14	🕒

5.9.1 Reset

All relays have the following three possibilities to reset the display of the unit as well as the output relay at jumper position J3=ON.

Manual Reset
- Pressing the push button <SELECT/RESET> for some time (about 3 s)

Electrical Reset
- Through applying auxiliary voltage to C8/D8

Software Reset
- The software reset has the same effect as the <SELECT/RESET> push button (see also communication protocol of RS485 interface)

The display can only be reset when the pickup is not present anymore (otherwise "TRIP" remains in display).

During resetting of the display the parameters are not affected.

5.9.2 Erasure of fault storage

To delete the trip store, the push button combination <SELECT/RESET> and <->, has to be pressed for about 3s. The display shows "wait".

6 Relay testing and commissioning

The following test instructions should help to verify the protection relay performance before or during commissioning of the protection system. To avoid a relay damage and to ensure a correct relay operation, be sure that:

- The auxiliary power supply rating corresponds to the auxiliary voltage on site.
- The rated frequency and rated voltage of the relay correspond to the plant data on site.
- The voltage transformer circuits are connected to the relay correctly.
- All signal circuits and output relay circuits are connected correctly.

6.1 Power-On

NOTE!
Prior to switch on the auxiliary power supply, be sure that the auxiliary supply voltage corresponds to the rated data on the type plate.

Switch on the auxiliary power supply to the relay and check that the message "ISEG" appears on the display and the self supervision alarm relay (watchdog) is energized (Contact terminals D7 and E7 closed).
It may happen that the relay is tripped because of under- voltage condition after power-on. (The message "TRIP" on the display and LED L1, L2, L3 and U< light up red). An undervoltage condition has been detected after power-on, because no input voltages are applied to the relay. In this case:

- Press the push button <ENTER>, thus entering into the setting mode. Now set the parameters U< and U<< to "EXIT" to block the undervoltage functions. After that, press the <SELECT/RESET> for app. 3 s to reset the LEDs and "TRIP" message.
- The undervoltage tripping after power on can also be eliminated by applying three phase rated voltages after power-on and reset the LED and "TRIP" message.
- Apply auxiliary voltage to the external blocking input (Terminals E8/D8) to inhibit the undervoltage functions (refer to 6.5) and press the <SELECT/RESET> for app. 3 s to reset the LEDs and "TRIP" message.

6.2 Testing the output relays

NOTE!
Prior to commencing this test, interrupt the trip circuit to the circuit breaker if tripping is not desired.

By pressing the push button <TRIP> once, the display shows the first part of the software version of the relay (e.g. „D08-"). By pressing the push button <TRIP> twice, the display shows the second part of the software version of the relay (e.g. „4.01". The software version should be quoted in all correspondence. Pressing the <TRIP> button once more, the display shows "PSW?". Please enter the correct password to proceed with the test. The message "TRI?" will follow. Confirm this message by pressing the push button <TRIP> again. All output relays should then be activated and the self supervision alarm relay (watchdog) be deenergized one after another with a time interval of 1 second. Thereafter, reset all output relays back to their normal positions by pressing the push button <SELECT/RESET>.

6.3 Checking the set values

By repeatedly pressing the push button <SELECT>, all relay set values may be checked. Set value modification can be done with the push button <+><-> and <ENTER>. For detailed information about that, please refer to chapter 4.3 of the description "MR – Digital multifunctional relays".

As relay input energizing quantities, three phase voltages should be applied to *MRN3* relay input circuits. Depending on the system conditions and the voltage transformer used, three voltages can be connected to the relay input circuits with either star or delta connection. In case of a star connection the phase-to-neutral voltage will be applied to the voltage input circuits, while the phase-to-phase voltages will be connected to the voltage input circuits in case of a delta connection. The voltage input connection must be set as a parameter, and should correspond with the actual voltage input connection:

Star connection:	Phase-to-neutral voltages will be measured and evaluated.
Delta connection:	Phase-to-phase voltages will be measured and evaluated.

6.4 Secondary injection test

6.4.1 Test equipment

- Voltmeter and frequency meter with class 1 or better,
- auxiliary power supply with the voltage corresponding to the rated data on the type plate,
- three-phase voltage supply unit with frequency regulation (Voltage: adjustable from 0 to 2 x U_N; Frequency: adjustable from 40 - 70 Hz),
- timer to measure the operating time (Accuracy class ±10 ms),
- switching device and
- Test leads and tools

6.5 Example of test circuit

For testing of the *MRN3* relay, a three phase voltage source with adjustable voltage and frequency is required. Figure 6.1 shows an example of a three-phase test circuit energizing the *MRN3* relay during test. The three phase voltages are applied to the relay in Y-connection.

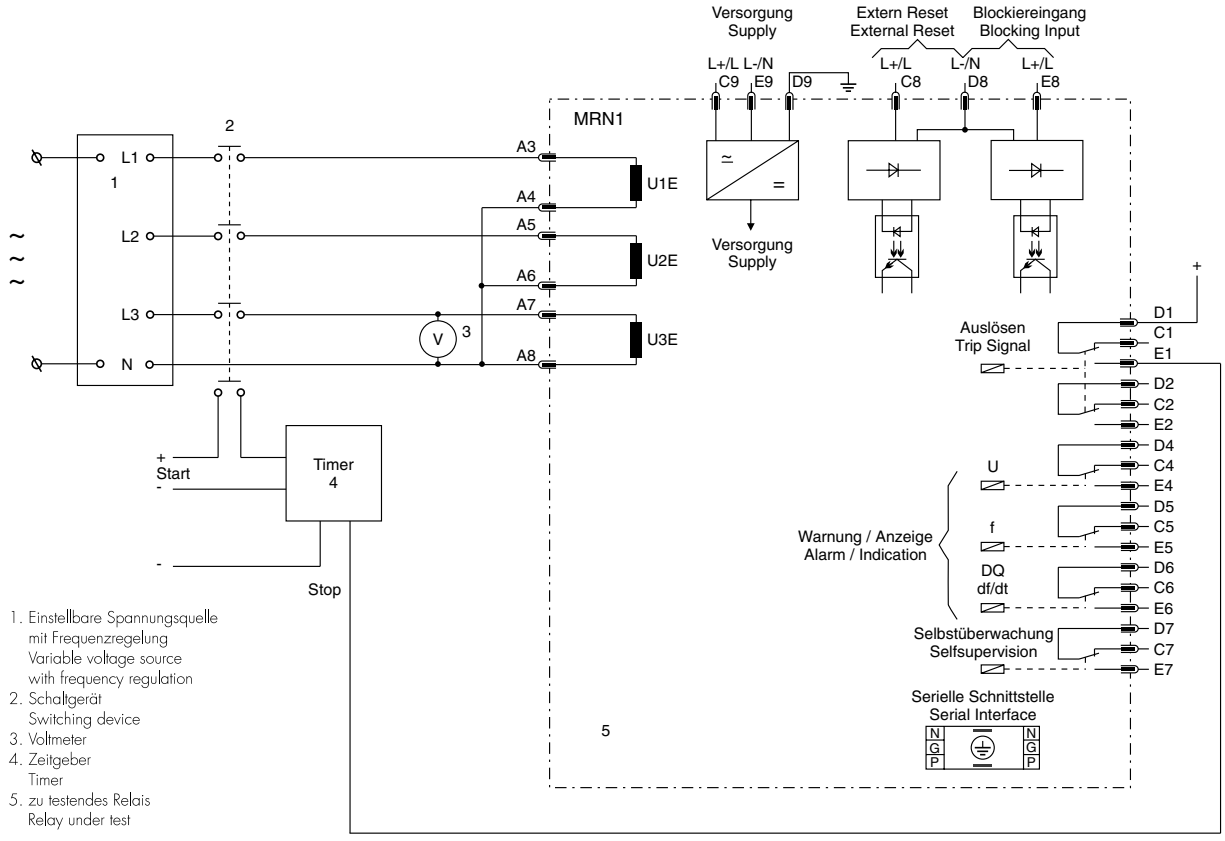


Figure 6.1: Test circuit

For testing the vector surge function of the relay, a test circuit which can produce phase angle change (vector surge) is required to simulate mains failures (please refer to chapter 6.5.6).

For testing the df/dt function of the relay, a special test equipment is required, which produces a constant rate of change of frequency.

6.5.1 Checking the input circuits and measuring functions

Apply three voltages of rated value to the voltage input circuits (terminals A3 - A8) of the relay. Check the measured voltages, frequency and vector surge on the display by pressing the push button <SELECT/RESET> repeatedly. The displayed measuring voltages (shown in Volt) are dependent on the wiring of the input voltage converters and the set transformation ratio.

The voltages are indicated on the display in volts.
At Y-connection:
- Phase-to-neutral voltages: LED L1, L2, L3

At Delta-connection:
- Phase-to-phase voltages: LED L1+L2, L2+L3, L3+L1

The frequency is indicated on the display in Hz: LED f (system frequency = 50.01Hz, Indication = 5001)
The vector surge is indicated on the display in degrees (for *MRN3-1*): LED $\Delta\Theta$ (Indication $\Delta\Theta$ in °)
The rate of change of frequency (LED df) is indicated on the display in Hz/s (for *MRN3-2*)

Change the voltages around the rated value and check the measured voltages on the display.
Change the system frequency around the rated frequency and check the measured frequency on the display.

Compare the voltage and frequency on display with the signal on voltmeter and frequency meter. The deviation for the voltage must not exceed 1% and for frequency <0.01 Hz.

By using an RMS-metering instrument, a greater deviation may be observed if the test voltage contains harmonics. Because the *MRN3* relay measures only the fundamental component of the input signals, the harmonics will be rejected by the internal DFFT-digital filter. Whereas the RMS-metering instrument measures the RMS-value of the input signals.

6.5.2 Checking the operating and reset ting values of the over/undervoltage functions

Note:
When the measuring voltage is connected or disconnected, vector surge tripping or df/dt tripping can occur. In order to ensure a trouble-free test procedure, the vector surge function or df/dt function of the relay have to be blocked before tests are started.

Apply three voltages with the rated value and gradually increase (decrease) the voltages until the relay starts, i.e. at the moment when the LED U> (or U<) lights up or the voltage alarm output relay (contact terminals D4/E4) is activated. Read the operating voltage indicated by the voltmeter. The deviation must not exceed 1% of the set operating value.

Furthermore, gradually decrease (increase) the voltages until the relay resets, i.e. the voltage alarm output relay is disengaged. Check that the dropout to pickup ratio for voltage is greater than 0.97 (for overvoltage function) or smaller than 1.03 (for undervoltage).

6.5.3 Checking the relay operating time of the over/undervoltage functions

To check the relay's operating time, a timer must be connected to the trip output relay contact (Contact terminals D1/E1). The timer should be started simultaneously with the voltage change from sound condition to a faulty condition and stopped by the trip relay contact. The operating time measured by timer should have a deviation about 3% of the set value or <20 ms.

6.5.4 Checking the operating and reset ting values of the over/underfrequency functions

Note:
Due to frequency changes, vector surge tripping or df/dt - tripping can occur during frequency tests. In order to ensure a trouble-free test procedure, the vector surge function or df/dt function of the relay have to be blocked before tests are started.
During frequency tests, each of the frequency elements should be tested separately. This makes it necessary that the other frequency elements of the relay have to be blocked by setting the frequency pickup values f_1 - f_3 to "EXIT". For testing the pickup and dropout to pickup values, the test frequency has to be increased (decreased) until the relay is engergized. This is indicated by lighting up of LEDs f_1 - f_3.
When comparing the values displayed with those of the frequency meter, the deviation must not exceed 0.01 Hz. The dropout to pickup values are ascertained by increasing (decreasing) the test frequency slowly until the output relay releases.
The dropout to pickup value for overfrequency must be >0.99, and for underfrequency <1.01.

6.5.5 Checking the relay operating time of the over/underfrequency functions

The operating time of the over/underfrequency functions can be tested in the similar manner as in chapter 6.5.3 for over/undervoltage functions.

6.5.6 Checking the vector surge function

With the help of an advanced relay test equipment a phase shift (vector surge) on the voltage signal can be obtained to test the vector surge function of *MRN3* relay. If there is no such testing facility available, a very simple simulation circuit may be used to test the vector surge function of the relay with a sufficient accuracy. Figure 6.2 shows the possibility to simulate a phase shift by means of a RC circuit. Closing or opening the switch S1 causes the phase angle of the input voltage to change depending on the adjustable resistor R.

The phase angle obtained may be calculated with the following formula and is almost independent on the test voltages.
In case of a 3-phase vector surge, the angle $\Delta\Theta$ can be calculated with the following formula if the parameters R_0, R and C are known:

$$\Delta\Theta = \text{arctg}\frac{1}{R_0 \cdot \omega \cdot C} - \text{arctg}\frac{1}{(R_0 + R) \cdot \omega \cdot C}$$

Example: R_0 = 1 Ohm, R = 363 Ohm, C = 3 µF

then: $\Delta\Theta \cong 19°$

Usually the voltage source impedance R_0 is negligible, hence R_0 may be assumed zero. Thus, the value of R may be calculated using the following simplified formula:

$$\Delta\Theta = 90° - \text{arctg}\ \frac{1}{R \cdot \omega \cdot C}$$

Note!
Using the above test circuit with single-phase vector surge, the resulting measured angle $\Delta\Theta$ is about half the value of $\Delta\Theta$ calculated for a 3-phase vector surge.
To make tripping possible during a one phase test procedure, the vector surge tripping has to be set to "1Ph".

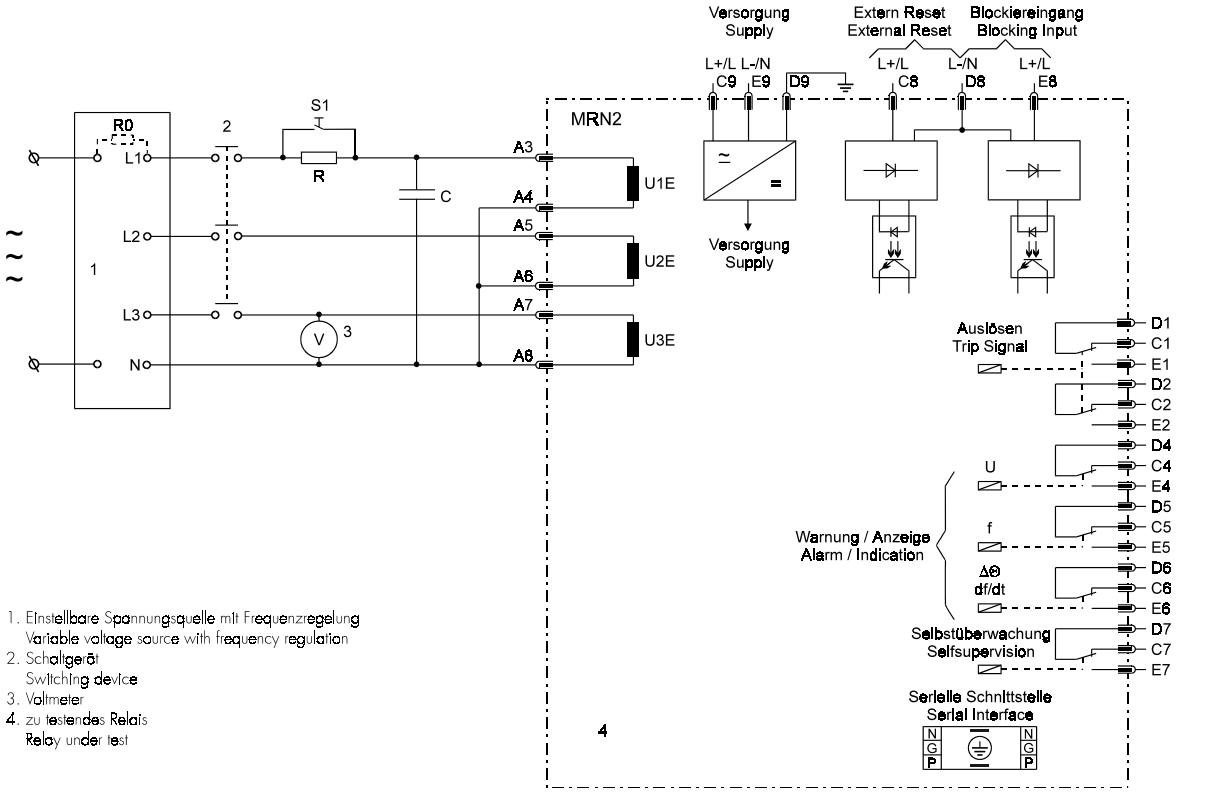

Figure 6.2: Test circuit for the vector surge function

6.5.7 Checking the external blocking and reset functions

The external blocking input is free programmable by the user.
To test the blocking function apply auxiliary supply voltage to the external blocking input of the relay (terminals E8/D8). Inject a test voltage which could cause tripping for the testes functions. Observe that there is no trip and alarm for those functions.

Remove the auxiliary supply voltage from the blocking input. Apply test voltages to trip the relay (message „TRIP" on the display). Return the test voltages to the sound condition and apply auxiliary supply voltage to the external reset input of the relay (terminals C8/D8). The display and LED indications should be reset immediately.

6.6 Primary injection test

Generally, a primary injection test could be carried out in the similar manner as the secondary injection test described above. With the difference that the protected power system should be, in this case, connected to the installed relays under test „on line", and the test voltages should be injected to the relay through the voltage transformers with the primary side energized. Since the cost and potential hazards are very high for such a test, primary injection tests are usually limited to very important protective relays in the power system.

Because of its powerful combined indicating and measuring functions, the *MRN3* relay may be tested in the manner of a primary injection test without extra expenditure and time consumption.

In actual service, for example, the measured voltage and frequency values on the *MRN3* relay display may be compared phase by phase with the concerned indications of the instruments of the switchboard to verify that the relay works and measures correctly.

6.7 Maintenance

Maintenance testing is generally done on site at regular intervals. These intervals vary among users depending on many factors: e.g. the type of protective relays employed; the importance of the primary equipment being protected; the user's past experience with the relay, etc.

For electromechanical or static relays, maintenance testing will be performed at least once a year according to the experiences. For digital relays like *MRN3*, this interval can be substantially longer. This is because:

- The *MRN3* relays are equipped with very wide self-supervision functions, so that many faults in the relay can be detected and signalised during service. Important: The self-supervision output relay must be connected to a central alarm panel!
- The combined measuring functions of *MRN3* relays enable supervision the relay functions during service.
- The combined TRIP test function of the *MRN3* relay allows to test the relay output circuits.

A testing interval of two years for maintenance will, therefore, be recommended.
During a maintenance test, the relay functions including the operating values and relay tripping times should be tested.

7 Technical data

7.1 Measuring input circuits

Rated data:	Nominal voltage U_N	100 V, 230 V, 400 V
	Nominal frequency f_N	40 - 70 Hz
Power consumption in voltage circuit:	<1 VA	
Thermal rating:	continuously	2 x U_N
Undervoltage lockout for frequency and vector surge measurement:	U< adjustable (5%...100% U_N)	

7.2 Common data

Dropout to pickup ratio:	for U>/U>> : >97%;	for U</U<< : <103%
	for f>/f>> : >99.98%;	for f</f<< : <100.02%
Dropout time:	60 ms	
Time lag error class index E:	±10 ms	
Minimum operating time:	40 ms	
Max. allowed interruption of the auxiliarxy supply without a facting the function of the device:	50 ms	
Influences on voltage measuring:		
Aux. voltage:	in the range 0.8 <U_H/U_{HN} <1.2 no additional influences to be measured	
Frequency:	in the range 0.8 <f / f_N <1.4 (for f_N = 50 Hz) <0.15% / Hz	
Harmonics:	up to 20% of the 3rd harmonic <0.1% per percent of the 3rd harmonic	
	up to 20% of the 5th harmonic <0.05% per percent of the 5th harmonic	
Influences on frequency measuring:		
Aux. voltage:	in the range <0.8 U_N/U_{HN} <1.2 no additional influences to be measured	
Frequency:	no influences	
Influences on delay time:	no additional influences to be measured	
GL-Approbation:	98776-96HH	
Bureau Veritas Approbation:	2650 6807 A00 H	

7.3 Setting ranges and steps

Function	Para-meter	Setting range	Steps	Tolerance
Transformer ratio	U_{prim}/U_{sek}	(SEC) 1.01...6500	0.01; 0.02; 0.05; 0.1; 0.2; 0.5; 1.0; 2.0; 5.0; 10; 20; 50	
Rated frequency	f_N	f = 50 Hz / f = 60 Hz		
Switch group	Δ/Y	Δ = Delta/Y = Stern		
Switch over	P2/FR	SET1/SET2/B_S2/R_S2/B_FR/R_FR/ S2_FR		
LED blinking at pick-up		FLSH/NOFL		
U</<<	U</<<	U_N = 100 V: 2...200 V (EXIT) U_N = 230 V: 2...460 V (EXIT) U_N = 400 V: 4...800 V (EXIT) 0.04...50 s (EXIT)	 1 V 1 V 2 V 0.01; 0.02; 0.05; 0.1; 0.2; 0.5; 1.0; 2.0 s	 ± 1 % of set value or < 0.3% U_N ±1% or ±15 ms

The thyristor blocks are controlled by Mita-Teknik's connection module WP2060 and perform a precise and soft connection between the wind turbine generator and the power supply grid.

- Must be mounted with sufficient cooling.
- The thyristor blocks are protected against overheating by the connection module.
- A specially developed circuit protects the thyristors from overloading.
- Part no.: Please see table next page

Mita-Teknik a/s

Controls for wind turbines
- we make a difference

- a reliable and complete concept

w i n d

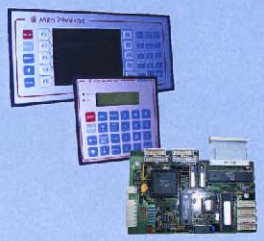
Mita-Teknik a/s
DK-8840 Rødkærsbro - Tel. +45 8665 8600 - Fax. +45 8665 9290
mail@mita-teknik.com - www.mita-teknik.com

Power Panels

Mita-Teknik's standard concept can be modified to fit any requirements. We customise power panels according to international standards.

Controllers

The WP3000 and the WP3100 control units are designed to control all types of wind turbines. Graphical displays can be connected by choice. Also a large number of extension circuit boards can be built in.



Grid Connection

The WP4060 grid connection module ensures safe grid connection without grid disturbances.

Accessories

Mita-Teknik delivers a number of accessories for intelligent surveillance - like sensors for detecting vibrations, wind speed, wind direction etc.

Weather and Grid Station

The Weather Station is equipped with an IC1000 control unit and is used for surveillance and data collection of wind direction, wind speed, temperature, and air pressure.

The Grid Station is equipped with a WP3000 control unit and is used for monitoring and surveying of Substations (High voltage).

Wind Turbine Control Software

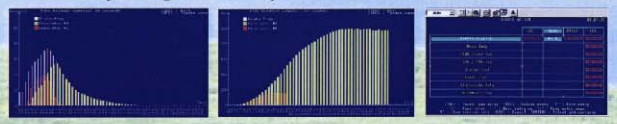
Mita-Teknik has a unique experience in developing wind turbine control software. Our programmers specialize in software which optimizes availability and production in each wind turbine. We have created an outstanding system for wind turbine analysis regarding fault analysis, turbine optimization and prototype running-in.

Management System

Direct connection to wind turbines is established through our Windows management system. This complete management system gives access to advanced statistics and on-line data.

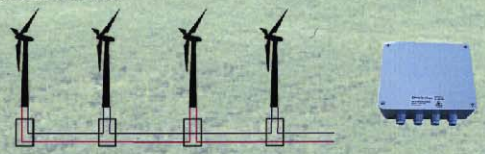
Service System

The system features are among other things downloading of programs, parameter settings and transfer of statistical data. Furthermore the Service System enables detailed stop and operation analysis in order to improve the wind turbine availability and profitability.



Communication

Mita-Teknik ensures a reliable data communication both using fibre optic convertion equipment and the public telephone network.



Training

Mita-Teknik offers customized training. This assures fast and efficient understanding of the software whether it concerns wind turbine control software, service software or management system.

Information

Hot-line service and follow-up characterises Mita-Teknik.
For further information about our wind power concept or Mita in general don't hesitate to contact our sales department or visit us at our homepage...

WP3000 Controller

- Intelligent controller for all types of wind turbines
- All control functions are integrated
- Advanced data collection and storage
- Flexible design to meet customer requirements
- Integrated realtime grid measurement
- Easily expandable
- Remote firmware up-date

Description

The WP3000 controller has been specially designed to control wind turbines - from stall to pitch with variable and non-variable speed. The WP3000 controller ensures optimal operation, active security and advanced data collection.

Hardware

Integrated I/O and COM-ports
The compact design of the WP3000 controller makes it noise immune and perfect for building-in with other components. Easily expandable with different extension interfaces. User-friendly design for error detection.

Integrated realtime grid measurement
Fast reaction towards grid disturbances/drops.

HMI text and graphics
Access to data in the turbine is possible using the text/graphic display or a laptop.

Internal turbine network
Possibility of constructing an internal network with more controllers from Mita.

Park network
Prepared for wind park configurations from small to large wind parks.
MNET and ARCNET

Software and Statistics

State based programme structure.
Integration of all operation functions and feedback.
The programming is undertaken in language “C” and can be uploaded via modem.

Access to the turbine
Remote access for/to parametrization and surveillance of the turbine.
Parameter and stored data are protected by passwords.

Storage of statistics
Life time statistics of standard data - such as availability, production, and consumption - daily, monthly and yearly.
Log/oscilloscope functions for advanced error detection.
100 line lists of status, events, access and alarm call.

WP3045 Fibre Optic Interface

- The WP3045 interface is compatible with all IC/WP-Controllers up to WP3100
- High flexibility
- Easy expansion of control units
- Plug-and-play installation
- Optimal lightning protection
- Adjustable baudrate

Description

The WP3045 is a standard optical fibre communication card used for safe serial communication. The card is a plug-and-play card which can be used in IC500, IC1000, WP1000, IC3000, WP3000 and WP3100 controllers.

The WP3045 can be used for internal machine communication and/or for network communication between more controllers/machines. The card uses 62.5µ glass optic fibre cable which provide the optimal lightning and overvoltage protection and make the card suitable for industrial use. The baud rate is flexible and can be set in the controller.

62.5µ optic fibre cable is suitable for fast communication over short and long distances, termination of the cable must be handled by professionals.

The maximum distance is calculated based on a power budget for the communication network. Please contact Mita-Teknik A/S for further information.

WP3046 RS232 Interface

- The WP3046 interface is compatible with all IC/WP-Controllers up to WP3100
- High flexibility
- Easy expansion of control units
- Plug-and-play installation
- Onboard lightning protection
- Adjustable baudrate

Description

The WP3046 is a standard RS232 communication card used for safe serial communication. The card is a plug-and-play card which can be used in IC500, IC1000, WP1000, IC3000, WP3000 and WP3100 controllers.
The WP3046 can be used for internal machine communication and/or for network communication between more controllers/machines.
The card has an on board lightning and overvoltage protection which make the card suitable for industrial use. The baudrate is flexible and can be set in the controller.
If the distance exceed 30 m, we recommend to convert the signal into optical fibre

WP3059 Display

- 4-line Text Display for IC/WP-Controllers
- Quick survey of functions and data in the wind turbine
- Userfriendly menu structure
- Designed for easy mounting

Description

The WP3059 Text Display is used with our IC/WP-control- lers and gives access to the turbine.

Features
LCD-display with four 20-character lines.
The display background light is automatically regulated according to the contrast.
The module emits a sound when a key is pressed.

Access to the turbine
Local access to parametri-zation and surveillancethe turbine.
Parameter and stored data are protected by passwords.

The WP3090 instrument trafo interface is an instrument trafo interface module which is used for measuring the 3-phased grid voltage on 690/400V systems.

- DIN-rail mounting.
- The WP3090 (Part no. 9723090) is produced in accordance with the demands in the DS/ EN ISO 9001-standard and is EMC tested according to EN50082-2 and EN50081-2.

WP4060 Connection Module

- The WP4060 connection module is used for soft connection of generators to the grid
- Contimuous safety test correct thyristor sequence
- Surveillance of too high temeprature on thryristors with bimetal sensor
- For 1- and 2 generator systems
- Possibility of throughout logging of all relevant data
- Download of log data through the IC/WP controllers

Description

The WP4060 connection module is used for soft connection of wind turbine genrators to the grid.
The Cos.phi circuit of the WP4060 ensures effective current control before, during and after the synchronous point.
The connection current is chosen as a parameter on the control unit.

The thyristors can be connected during low production. The parameters for the opening of the thyristors are set on the control unit.
The WP4060 has a built-in DELTA PHI circuit, which measures whether the generator receive or transmits power.

The module has a built-in phase detecting circuit, which prevents connection if the phase sequence is un correct.
Soft connection of generators with either “6-wire cable” or “3-wire cable connection”. With real time auto detector

The WP4060 can replace our former connection module, WP2060, if the DELTA PHI function is de-activated.

Numéros des publications

Depuis le 1er janvier 1997, les publications de la CEI sont numérotées à partir de 60000.

Publications consolidées

Les versions consolidées de certaines publications de la CEI incorporant les amendements sont disponibles. Par exemple, les numéros d'édition 1.0, 1.1 et 1.2 indiquent respectivement la publication de base, la publication de base incorporant l'amendement 1, et la publication de base incorporant les amendements 1 et 2.

Validité de la présente publication

Le contenu technique des publications de la CEI est constamment revu par la CEI afin qu'il reflète l'état actuel de la technique.

Des renseignements relatifs à la date de reconfirmation de la publication sont disponibles dans le Catalogue de la CEI.

Les renseignements relatifs à des questions à l'étude et des travaux en cours entrepris par le comité technique qui a établi cette publication, ainsi que la liste des publications établies, se trouvent dans les documents ci-dessous:

- **«Site web» de la CEI***
- **Catalogue des publications de la CEI**
  Publié annuellement et mis à jour régulièrement
  (Catalogue en ligne)*
- **Bulletin de la CEI**
  Disponible à la fois au «site web» de la CEI* et comme périodique imprimé

Terminologie, symboles graphiques et littéraux

En ce qui concerne la terminologie générale, le lecteur se reportera à la CEI 60050: *Vocabulaire Electrotechnique International* (VEI).

Pour les symboles graphiques, les symboles littéraux et les signes d'usage général approuvés par la CEI, le lecteur consultera la CEI 60027: *Symboles littéraux à utiliser en électrotechnique,* la CEI 60417: S*ymboles graphiques utilisables sur le matériel. Index, relevé et compilation des feuilles individuelles,* et la CEI 60617: *Symboles graphiques pour schémas.*

* Voir adresse «site web» sur la page de titre.

Numbering

As from 1 January 1997 all IEC publications are issued with a designation in the 60000 series.

Consolidated publications

Consolidated versions of some IEC publications including amendments are available. For example, edition numbers 1.0, 1.1 and 1.2 refer, respectively, to the base publication, the base publication incorporating amendment 1 and the base publication incorporating amendments 1 and 2.

Validity of this publication

The technical content of IEC publications is kept under constant review by the IEC, thus ensuring that the content reflects current technology.

Information relating to the date of the reconfirmation of the publication is available in the IEC catalogue.

Information on the subjects under consideration and work in progress undertaken by the technical committee which has prepared this publication, as well as the list of publications issued, is to be found at the following IEC sources:

- **IEC web site***
- **Catalogue of IEC publications**
  Published yearly with regular updates
  (On-line catalogue)*
- **IEC Bulletin**
  Available both at the IEC web site* and as a printed periodical

Terminology, graphical and letter symbols

For general terminology, readers are referred to IEC 60050: *International Electrotechnical Vocabulary* (IEV).

For graphical symbols, and letter symbols and signs approved by the IEC for general use, readers are referred to publications IEC 60027: *Letter symbols to be used in electrical technology*, IEC 60417: *Graphical symbols for use on equipment. Index, survey and compilation of the single sheets* and IEC 60617: *Graphical symbols for diagrams.*

INTRODUCTION

En 1991, le CE 2 a décidé de rédiger la CEI 60034-1 pour en grouper les prescriptions en un ordre plus logique. Le résultat en est la dixième édition qui a maintenant priorité sur la neuvième édition.

Il n'y a pas de différence entre les prescriptions de la dixième édition et celles de la neuvième édition (incluant son amendement 1) et il est prévu qu'à court terme, d'autres amendements porteront simultanément sur la neuvième et la dixième édition.

La neuvième édition sera retirée d'ici moins de deux ans. Cela laissera le temps nécessaire à la mise à jour de toute autre norme se référant à des articles particuliers de la CEI 60034-1 et permettra aux utilisateurs de la norme de faire les changements qu'ils jugeront nécessaires dans leur propre documentation.

Pour faciliter ce changement, les références croisées (dans les deux sens) sont données en annexe B.

INTRODUCTION

In 1991, TC2 decided to edit IEC 60034-1 to group the requirements in a more logical order. The result is edition 10 which now takes precedence over edition 9.

There is no difference between the technical requirements of edition 10 and of edition 9 (including amendment number 1) and it is intended that in the short term any further amendments will be introduced simultaneously in edition 9 and edition 10.

Edition 9 will be withdrawn within two years. This will allow time for the updating of any other standards which refer to specific clauses of IEC 60034-1 and for users of the standard to make such changes as they judge necessary in their own documentation.

To facilitate these processes, cross-references (both ways) are listed in annex B.

COMMISSION ÉLECTROTECHNIQUE INTERNATIONALE

_____

MACHINES ÉLECTRIQUES TOURNANTES –

Partie 1: Caractéristiques assignées et caractéristiques de fonctionnement

AVANT-PROPOS

1) La CEI (Commission Electrotechnique Internationale) est une organisation mondiale de normalisation composée de l'ensemble des comités électrotechniques nationaux (Comités nationaux de la CEI). La CEI a pour objet de favoriser la coopération internationale pour toutes les questions de normalisation dans les domaines de l'électricité et de l'électronique. A cet effet, la CEI, entre autres activités, publie des Normes Internationales. Leur élaboration est confiée à des comités d'études, aux travaux desquels tout Comité national intéressé par le sujet traité peut participer. Les organisations internationales, gouvernementales et non gouvernementales, en liaison avec la CEI, participent également aux travaux. La CEI collabore étroitement avec l'Organisation Internationale de Normalisation (ISO), selon des conditions fixées par accord entre les deux organisations.

2) Les décisions ou accords officiels de la CEI concernant les questions techniques, représentent, dans la mesure du possible un accord international sur les sujets étudiés, étant donné que les Comités nationaux intéressés sont représentés dans chaque comité d'études.

3) Les documents produits se présentent sous la forme de recommandations internationales. Ils sont publiés comme normes, rapports techniques ou guides et agréés comme tels par les Comités nationaux.

4) Dans le but d'encourager l'unification internationale, les Comités nationaux de la CEI s'engagent à appliquer de façon transparente, dans toute la mesure possible, les Normes internationales de la CEI dans leurs normes nationales et régionales. Toute divergence entre la norme de la CEI et la norme nationale ou régionale correspondante doit être indiquée en termes clairs dans cette dernière.

5) La CEI n'a fixé aucune procédure concernant le marquage comme indication d'approbation et sa responsabilité n'est pas engagée quand un matériel est déclaré conforme à l'une de ses normes.

6) L'attention est attirée sur le fait que certains des éléments de la présente Norme internationale peuvent faire l'objet de droits de propriété intellectuelle ou de droits analogues. La CEI ne saurait être tenue pour responsable de ne pas avoir identifié de tels droits de propriété et de ne pas avoir signalé leur existence.

La Norme internationale CEI 60034-1 a été établie par le comité d'études 2 de la CEI: Machines tournantes.

La présente version consolidée de la CEI 60034-1 est issue de la dixième édition (1996) [documents 2/933/FDIS et 2/969/RVD], de son amendement 1 (1997) [documents 2/956/FDIS et 2/984/RVD] et de son amendement 2 (1999) [documents 2/1031+1055+1056/FDIS et 2/1058+1070+1071/RVD].

Elle porte le numéro d'édition 10.2.

Une ligne verticale dans la marge indique où la publication de base a été modifiée par les amendements 1 et 2.

Les annexes A et B sont données uniquement à titre d'information.

INTERNATIONAL ELECTROTECHNICAL COMMISSION

_____

ROTATING ELECTRICAL MACHINES –

Part 1: Rating and performance

FOREWORD

1) The IEC (International Electrotechnical Commission) is a worldwide organization for standardization comprising all national electrotechnical committees (IEC National Committees). The object of the IEC is to promote international co-operation on all questions concerning standardization in the electrical and electronic fields. To this end and in addition to other activities, the IEC publishes International Standards. Their preparation is entrusted to technical committees; any IEC National Committee interested in the subject dealt with may participate in this preparatory work. International, governmental and non-governmental organizations liaising with the IEC also participate in this preparation. The IEC collaborates closely with the International Organization for Standardization (ISO) in accordance with conditions determined by agreement between the two organizations.

2) The formal decisions or agreements of the IEC on technical matters express, as nearly as possible, an international consensus of opinion on the relevant subjects since each technical committee has representation from all interested National Committees.

3) The documents produced have the form of recommendations for international use and are published in the form of standards, technical reports or guides and they are accepted by the National Committees in that sense.

4) In order to promote international unification, IEC National Committees undertake to apply IEC International Standards transparently to the maximum extent possible in their national and regional standards. Any divergence between the IEC Standard and the corresponding national or regional standard shall be clearly indicated in the latter.

5) The IEC provides no marking procedure to indicate its approval and cannot be rendered responsible for any equipment declared to be in conformity with one of its standards.

6) Attention is drawn to the possibility that some of the elements of this International Standard may be the subject of patent rights. The IEC shall not be held responsible for identifying any or all such patent rights.

International standard IEC 60034-1 has been prepared by IEC technical committee 2: Rotating machinery.

This consolidated version of IEC 60034-1 is based on the tenth edition (1996) [documents 2/933/FDIS and 2/969/RVD], its amendment 1 (1997) [documents 2/956/FDIS and 2/984/RVD] and amendment 2 (1999) [documents 2/1031+1055+1056/FDIS and 2/1058+1070+1071/RVD].

It bears the edition number 10.2.

A vertical line in the margin shows where the base publication has been modified by amendments 1 and 2.

Annexes A and B are for information only.

MACHINES ÉLECTRIQUES TOURNANTES –

Partie 1: Caractéristiques assignées et caractéristiques de fonctionnement

Section 1: Généralités

1.1 Domaine d'application

La présente norme est applicable à toutes les machines électriques tournantes à l'exception de celles qui font l'objet d'autres normes de la CEI, par exemple la CEI 60349.

Les machines comprises dans le domaine d'application de la présente norme peuvent également être soumises à des prescriptions nouvelles, modifiées ou complémentaires figurant dans d'autres publications – par exemple, la CEI 60079 et la CEI 60092.

NOTE S'il est nécessaire de modifier certains articles de la présente norme afin de permettre des applications spéciales, par exemple pour les matériels soumis à des rayonnements ou les matériels aérospatiaux, tous les autres articles restent valables, pour autant qu'ils ne soient pas en contradiction avec ces spécifications particulières.

1.2 Références normatives

Les documents normatifs suivants contiennent des dispositions qui, par suite de la référence qui y est faite, constituent des dispositions valables pour la présente partie de la CEI 60034. Au moment de la publication, les éditions indiquées étaient en vigueur. Tout document normatif est sujet à révision et les parties prenantes aux accords fondés sur la présente partie de la CEI 60034 sont invitées à rechercher la possibilité d'appliquer les éditions les plus récentes des documents normatifs indiqués ci-après. Les membres de la CEI et de l'ISO possèdent le registre des Normes internationales en vigueur.

ROTATING ELECTRICAL MACHINES –

Part 1: Rating and performance

Section 1: General

1.1 Scope

This standard is applicable to all rotating electrical machines except those covered by other IEC standards – for example, IEC 60349.

Machines within the scope of this standard may also be subject to superseding, modifying or additional requirements in other publications – for example, IEC 60079, and IEC 60092.

NOTE If particular clauses of this standard are modified to meet special applications, for example machines subject to radioactivity or machines for aerospace, all other clauses apply in so far as they are compatible.

1.2 Normative references

The following normative documents contain provisions which, through reference in this text, constitute provisions of this part of IEC 60034. At the time of publication, the editions indicated were valid. All normative documents are subject to revision, and parties to agreements based on this International Standard are encouraged to investigate the possibility of applying the most recent editions of the normative documents indicated below. Members of IEC and ISO maintain registers of currently valid International Standards.

Section 2: Définitions

Pour les besoins de la présente Norme internationale, les définitions de la CEI 60050(411) s'appliquent ainsi que les définitions ci-après.

Pour des définitions autres que celles de 2.17 à 2.22 concernant les modes et les fluides de refroidissement, se référer à la CEI 60034-6.

Au sens de la présente norme, le terme «accord» signifie «accord entre le constructeur et l'acheteur».

2.1
valeur assignée
valeur d'une grandeur fixée, généralement par le constructeur, pour un fonctionnement spécifié d'une machine [VEI 411-51-23]

NOTE La tension assignée ou plage de tensions assignées est la tension assignée ou plage de tensions assignées entre phases aux bornes.

2.2
caractéristiques assignées
ensemble des valeurs assignées et des conditions de fonctionnement [VEI 411-51-24]

2.3
puissance assignée
valeur de la puissance incluse dans les caractéristiques assignées

2.4
charge
ensemble des valeurs des grandeurs électriques et mécaniques qui caractérisent les exigences imposées à une machine tournante par un circuit électrique ou un dispositif mécanique, à un instant donné [VEI 411-51-01]

2.5
fonctionnement à vide
état de fonctionnement d'une machine tournant à puissance nulle (mais les autres conditions étant les conditions normales de fonctionnement) [VEI 411-51-02 modifié]

2.6
pleine charge
charge amenant une machine à fonctionner à ses caractéristiques assignées [VEI 411-51-10]

2.7
valeur de pleine charge
valeur d'une grandeur pour une machine fonctionnant à pleine charge [VEI 411-51-11]

NOTE Cette notion est applicable à la puissance, au couple, au courant, à la vitesse, etc.

2.8
repos
absence complète de tout mouvement et de toute alimentation électrique ou de tout entraînement mécanique [VEI 411-51-03]

Section 2: Definitions

For the purpose of this International Standard, the definitions in IEC 60050(411) and the following definitions apply.

For definitions, other than those in 2.17 to 2.22, concerning cooling and coolants, reference should be made to IEC 60034-6.

For the purpose of this standard, the term 'agreement' means 'agreement between the manufacturer and purchaser'.

2.1
rated value
a quantity value assigned, generally by a manufacturer, for a specified operating condition of a machine [IEV 411-51-23]

NOTE The rated voltage or voltage range is the rated voltage or voltage range between lines at the terminals.

2.2
rating
the set of rated values and operating conditions [IEV 411-51-24]

2.3
rated output
the value of the output included in the rating

2.4
load
all the values of the electrical and mechanical quantities that signify the demand made on a rotating machine by an electrical circuit or a mechanism at a given instant [IEV 411-51-01]

2.5
no-load (operation)
the state of a machine rotating with zero output power (but under otherwise normal operating conditions) [IEV 411-51-02, modified]

2.6
full load
the load which causes a machine to operate at its rating [IEV 411-51-10]

2.7
full load value
a quantity value for a machine operating at full load. [IEV 411-51-11]

NOTE This concept applies to power, torque, current, speed, etc.

2.8
rest and de-energized
the complete absence of all movement and of all electrical supply or mechanical drive
[IEV 411-51-03]

2.9
service
stipulation de la charge (des charges) à laquelle (auxquelles) la machine est soumise, y compris, le cas échéant, les périodes de démarrage, de freinage électrique, de fonctionnement à vide et de repos, ainsi que leurs durées et leur ordre de succession dans le temps [VEI 411-51-06]

2.10
service type
service continu, temporaire ou périodique comprenant une ou plusieurs charges qui restent constantes pendant la durée spécifiée ou service non périodique pendant lequel généralement la charge et la vitesse varient dans la plage de fonctionnement admissible [VEI 411-51-13]

2.11
facteur de marche
rapport entre la période de fonctionnement en charge, y compris le démarrage et le freinage électrique, à la durée du cycle de service, exprimé en pourcentage [VEI 411-51-09]

2.12
couple à rotor bloqué
couple mesuré le plus faible que développe le moteur sur son bout d'arbre d'entraînement, quand son rotor est maintenu bloqué quelle que soit sa position angulaire et qu'il est alimenté à tension et fréquence assignées [VEI 411-48-06]

2.13
courant à rotor bloqué
valeur efficace la plus élevée du courant en régime établi, absorbé par le moteur lorsqu'il est alimenté aux tension et fréquence assignées et que son rotor est maintenu bloqué quelle que soit sa position angulaire [VEI 411-48-16]

2.14
couple minimal pendant le démarrage (d'un moteur à courant alternatif)
valeur la plus faible du couple asynchrone en régime établi, que le moteur développe entre la vitesse nulle et la vitesse qui correspond au couple maximal (couple de décrochage) lorsque le moteur est alimenté à la tension et à la fréquence assignées

Cette définition ne s'applique pas au cas de moteurs asynchrones dont le couple décroît continuellement lorsque la vitesse augmente.

NOTE En plus des couples asynchrones en régime établi, il existe, à des vitesses spécifiques, des couples harmoniques synchrones qui sont fonction de l'angle de charge du rotor.

A de telles vitesses, le couple d'accélération peut être négatif pour certains angles de charge du rotor.

L'expérience et le calcul montrent que c'est une condition de fonctionnement instable et qu'en conséquence les couples harmoniques synchrones n'empêchent pas l'accélération du moteur et sont exclus de cette définition.

2.15
couple maximal (couple de décrochage) (d'un moteur à courant alternatif)
valeur maximale en régime établi du couple asynchrone que le moteur développe sans chute brutale de vitesse, lorsqu'il est alimenté à tension et fréquence assignées

Cette définition ne s'applique pas au cas des moteurs asynchrones dont le couple décroît continuellement lorsque la vitesse augmente.

2.16
couple de décrochage synchrone (d'un moteur)
couple le plus élevé que développe un moteur synchrone à sa température de fonctionnement et à la vitesse de synchronisme, à tension, fréquence et excitation assignées

2.9
duty
the statement of the load(s) to which the machine is subjected, including, if applicable, starting, electric braking, no-load and rest and de-energized periods, and including their durations and sequence in time [IEV 411-51-06]

2.10
duty type
a continuous, short-time or periodic duty, comprising one or more loads remaining constant for the duration specified, or a non-periodic duty in which generally load and speed vary within the permissible operating range [IEV 411-51-13]

2.11
cyclic duration factor
the ratio between the period of loading, including starting and electric braking, and the duration of the duty cycle, expressed as a percentage [IEV 411-51-09]

2.12
locked-rotor torque
the smallest measured torque the motor develops at its shaft and with the rotor locked, over all its angular positions at rated voltage and frequency [IEV 411-48-06]

2.13
locked rotor current
the greatest steady-state r.m.s. current taken from the line with the motor held at rest, over all angular positions of its rotor, at rated voltage and frequency [IEV 411-48-16]

2.14
pull-up torque (of an a.c. motor)
the smallest value of the steady-state asynchronous torque which the motor develops between zero speed and the speed which corresponds to the breakdown torque, when the motor is supplied at the rated voltage and frequency

This definition does not apply to those asynchronous motors of which the torque continually decreases with increase in speed.

NOTE In addition to the steady-state asynchronous torques, harmonic synchronous torques, which are a function of rotor load angle, will be present at specific speeds.

At such speeds the accelerating torque may be negative for some rotor load angles.

Experience and calculation show this to be an unstable operating condition and therefore harmonic synchronous torques do not prevent motor acceleration and are excluded from this definition.

2.15
breakdown torque (of an a.c. motor)
the maximum value of the steady-state asynchronous torque which the motor develops without an abrupt drop in speed, when the motor is supplied at the rated voltage and frequency

This definition does not apply to those asynchronous motors of which the torque continually decreases with increase in speed.

2.16
pull-out torque (of a synchronous motor)
the maximum torque which the synchronous motor develops at operating temperature and at synchronous speed with rated voltage, frequency and field current

2.17
refroidissement
opération par laquelle de la chaleur provenant des pertes produites dans une machine est cédée à un fluide de refroidissement primaire qui peut être continûment remplacé ou être lui-même refroidi dans un échangeur de chaleur par un fluide de refroidissement secondaire [VEI 411-44-01]

2.18
fluide de refroidissement
fluide, liquide ou gaz, par l'intermédiaire duquel la chaleur est transférée [VEI 411-44-02]

2.19
fluide de refroidissement primaire
fluide, liquide ou gaz, qui, se trouvant à une température inférieure à celle des pièces de la machine et en contact avec celles-ci, transporte la chaleur cédée par ces pièces [VEI 411-44-03]

2.20
fluide de refroidissement secondaire
fluide, liquide ou gaz, qui, se trouvant à une température inférieure à celle du fluide de refroidissement primaire, transporte la chaleur cédée par ce fluide primaire au moyen d'un échangeur de chaleur ou à travers la surface extérieure de la machine [VEI 411-44-04]

2.21
enroulement à refroidissement direct (refroidissement interne)[1)]
enroulement refroidi principalement par un fluide de refroidissement s'écoulant en contact direct avec la partie refroidie à travers des passages creux, tubes, conduits ou canaux qui, quelle que soit leur orientation, forment partie intégrante de l'enroulement à l'intérieur de l'isolation principale [VEI 411-44-08]

2.22
enroulement à refroidissement indirect[1)]
tout enroulement autre qu'un enroulement à refroidissement direct [VEI 411-4-09]

2.23
isolation supplémentaire
isolation indépendante prévue en plus de l'isolation principale, en vue d'assurer la protection contre les chocs électriques en cas de défaut survenant dans l'isolation principale

2.24
moment d'inertie
somme (intégrale) des produits des masses élémentaires d'un corps par le carré de leurs distances (radiales) par rapport à un axe donné

2.25
équilibre thermique
état atteint lorsque les échauffements des diverses parties de la machine ne varient pas de plus d'un gradient de 2 K par heure [VEI 411-51-08]

NOTE On peut déterminer l'équilibre thermique à partir d'un tracé de l'échauffement en fonction du temps, lorsque les droites entre points pris en début et fin de chacun de deux intervalles de temps raisonnables successifs ont une pente de moins de 2 K par heure.

[1)] Dans tous les cas où «indirect» ou «direct» n'est pas indiqué, il s'agit d'un enroulement à refroidissement indirect.

2.17
cooling
a procedure by means of which heat resulting from losses occurring in a machine is given up to a primary coolant, which may be continuously replaced or may itself be cooled by a secondary coolant in a heat exchanger [IEV 411-44-01]

2.18
coolant
a medium, liquid or gas, by means of which heat is transferred [IEV 411-44-02]

2.19
primary coolant
a medium, liquid or gas, which, being at a lower temperature than a part of a machine and in contact with it, removes heat from that part [IEV 411-44-03]

2.20
secondary coolant
a medium, liquid or gas, which, being at a lower temperature than the primary coolant, removes the heat given up by this primary coolant by means of a heat exchanger or through the external surface of the machine [IEV 411-44-04]

2.21
direct cooled (inner cooled) winding[1)]
a winding mainly cooled by coolant flowing in direct contact with the cooled part through hollow conductors, tubes, ducts or channels which, regardless of their orientation, form an integral part of the winding inside the main insulation [IEV 411-44-08]

2.22
indirect cooled winding[1)]
any winding other than a direct cooled winding [IEV 411-44-09]

2.23
supplementary insulation
an independent insulation applied in addition to the main insulation in order to ensure protection against electric shock in the event of failure of the main insulation

2.24
moment of inertia
the sum (integral) of the products of the mass elements of a body and the squares of their distances (radii) from a given axis

2.25
thermal equilibrium
the state reached when the temperature rises of the several parts of the machine do not vary by more than a gradient of 2 K per hour [IEV 411-51-08]

NOTE Thermal equilibrium may be determined from the time-temperature rise plot when the straight lines between points at the beginning and end of two successive reasonable intervals each have a gradient of less than 2 K per hour.

[1)] In all cases when ‘indirect’ or ‘direct’ is not stated, an indirect cooled winding is implied.

2.26
constante de temps thermique équivalente
constante de temps qui, en remplaçant plusieurs constantes de temps individuelles, détermine approximativement l'évolution de la température dans un enroulement après une variation de courant en échelon

2.27
enroulement enrobé
enroulement complètement enfermé ou noyé dans un isolant moulé [VEI 411-39-06]

2.28
valeur assignée du facteur de forme du courant continu fourni à l'induit d'un moteur à courant continu par un convertisseur statique de puissance
rapport de la valeur efficace maximale admissible du courant $I_{\text{eff.maxN}}$ à sa valeur moyenne I_{moyN} (valeur moyenne intégrée sur une période) aux conditions assignées:

$$k_{\text{fN}} = \frac{I_{\text{eff.maxN}}}{I_{\text{moyN}}}$$

2.29
facteur d'ondulation du courant
rapport de la différence entre la valeur maximale I_{max} et la valeur minimale I_{min} d'un courant ondulé au double de sa valeur moyenne I_{moy} (valeur moyenne intégrée sur une période):

$$q_{\text{i}} = \frac{I_{\text{max}} - I_{\text{min}}}{2 \times I_{\text{moy}}}$$

NOTE Pour de faibles valeurs d'ondulation du courant, le facteur d'ondulation peut être approché par la formule suivante:

$$q_{\text{i}} = \frac{I_{\text{max}} - I_{\text{min}}}{I_{\text{max}} + I_{\text{min}}}$$

La formule ci-dessus peut être utilisée en tant qu'approximation si la valeur calculée résultante de q_{i} est inférieure ou égale à 0,4.

Section 3: Services

3.1 Spécification du service

C'est à l'acheteur qu'incombe la responsabilité de spécifier le service. L'acheteur peut décrire le service par l'une des méthodes suivantes:

a) numériquement, si la charge ne varie pas ou varie de façon connue;

b) graphiquement, par une représentation des grandeurs variables en fonction du temps;

c) en choisissant l'un des services types S1 à S10 qui est au moins aussi sévère que le service prévu.

Le service type peut être désigné par l'abréviation appropriée spécifiée en 3.2, à la suite de la valeur de la charge.

Une formulation du facteur de marche est indiquée sous chaque figure appropriée de service type.

2.26
thermal equivalent time constant
the time constant, replacing several individual time constants, which determines approximately the temperature course in a winding after a step-wise current change

2.27
encapsulated winding
a winding which is completely enclosed or sealed by moulded insulation [IEV 411-39-06]

2.28
rated form factor of direct current supplied to a d.c. motor armature from a static power converter
the ratio of the r.m.s. maximum permissible value of the current $I_{\text{rms, maxN}}$ to its average value I_{avN} (mean value integrated over one period) at rated conditions:

$$k_{\text{fN}} = \frac{I_{\text{rms, maxN}}}{I_{\text{avN}}}$$

2.29
current ripple factor
the ratio of the difference between the maximum value I_{max} and the minimum value I_{min} of an undulating current to two times the average value I_{av} (mean value integrated over one period):

$$q_{\text{i}} = \frac{I_{\text{max}} - I_{\text{min}}}{2 \times I_{\text{av}}}$$

NOTE For small values of current ripple the ripple factor may be approximated by the following expression:

$$q_{\text{i}} = \frac{I_{\text{max}} - I_{\text{min}}}{I_{\text{max}} + I_{\text{min}}}$$

The above expression may be used as an approximation if the resulting calculated value of q_{i} is equal to or less than 0,4.

Section 3: Duty

3.1 Declaration of duty

It is the responsibility of the purchaser to declare the duty. The purchaser may describe the duty by one of the following:

a) numerically, where the load does not vary or where it varies in a known manner;

b) as a time sequence graph of the variable quantities;

c) by selecting one of the duty types S1 to S10 that is no less onerous than the expected duty.

The duty type shall be designated by the appropriate abbreviation, specified in 3.2, written after the value of the load.

An expression for the cyclic duration factor is given in the relevant duty type figure.

Normalement l'acheteur ne peut pas fournir une valeur au moment d'inertie du moteur (J_M) ni à l'espérance de vie thermique en valeur relative (TL), voir annexe A. Ces valeurs sont fournies par le constructeur.

Lorsque l'acheteur ne stipule pas de service, le constructeur doit considérer que le service type S1 (service continu) est applicable.

3.2 Services types

3.2.1 Service type S1 – Service continu

Fonctionnement à charge constante maintenue pendant une durée suffisante pour que la machine atteigne l'équilibre thermique, voir figure 1.

L'abréviation appropriée est S1.

3.2.2 Service type S2 – Service temporaire

Fonctionnement à charge constante pendant un temps déterminé, moindre que celui requis pour atteindre l'équilibre thermique, suivi d'un temps de repos d'une durée suffisante pour rétablir à 2 K près l'égalité de température entre la machine et le fluide de refroidissement, voir figure 2.

L'abréviation appropriée est S2, suivi de la valeur de la durée du service.

Exemple: S2 60 min.

3.2.3 Service type S3 – Service intermittent périodique [2)]

Suite de cycles de service identiques comprenant chacun un temps de fonctionnement à charge constante et un temps de repos, voir figure 3. Dans ce service, le cycle est tel que le courant de démarrage n'affecte pas l'échauffement de façon significative.

L'abréviation appropriée est S3, suivi de la valeur du facteur de marche.

Exemple: S3 25 %.

3.2.4 Service type S4 – Service intermittent périodique à démarrage [2)]

Suite de cycles de service identiques comprenant chacun un temps non négligeable de démarrage, un temps de fonctionnement à charge constante et un temps de repos, voir figure 4.

L'abréviation appropriée est S4, suivi des valeurs du facteur de charge, du moment d'inertie du moteur (J_M) et du moment d'inertie de la charge (J_{ext}), tous deux rapportés à l'arbre du moteur.

Exemple: S4 25 % J_M = 0,15 kg × m² J_{ext} = 0,7 kg × m²

3.2.5 Service type S5 – Service intermittent périodique à freinage électrique [2)]

Suite de cycles de service identiques comprenant chacun un temps de démarrage, un temps de fonctionnement à charge constante, un temps de freinage électrique et un temps de repos, voir figure 5.

[2)] Un service type périodique implique que l'équilibre thermique n'est pas atteint pendant la période de charge.

The purchaser normally cannot provide values for the moment of inertia of the motor (J_M) or the relative thermal life expectancy (TL), see annex A. These values are provided by the manufacturer.

Where the purchaser does not declare a duty, the manufacturer shall assume that duty type S1 (continuous running duty) applies.

3.2 Duty types

3.2.1 Duty type S1 – Continuous running duty

Operation at a constant load maintained for sufficient time to allow the machine to reach thermal equilibrium, see figure 1.

The appropriate abbreviation is S1.

3.2.2 Duty type S2 – Short-time duty

Operation at constant load for a given time, less than that required to reach thermal equilibrium, followed by a time at rest and de-energized, of sufficient duration to re-establish machine temperatures within 2 K of the coolant temperature, see figure 2.

The appropriate abbreviation is S2, followed by an indication of the duration of the duty,

Example: S2 60 min

3.2.3 Duty type S3 – Intermittent periodic duty [2)]

A sequence of identical duty cycles, each including a time of operation at constant load and a time at rest and de-energized, see figure 3. In this duty, the cycle is such that the starting current does not significantly affect the temperature rise.

The appropriate abbreviation is S3, followed by the cyclic duration factor.

Example: S3 25 %

3.2.4 Duty type S4 – Intermittent periodic duty with starting [2)]

A sequence of identical duty cycles, each cycle including a significant starting time, a time of operation at constant load and a time at rest and de-energized, see figure 4.

The appropriate abbreviation is S4, followed by the cyclic duration factor, the moment of inertia of the motor (J_M) and the moment of inertia of the load ($J_{ext)}$, both referred to the motor shaft.

Example: S4 25 % $J_M = 0{,}15\ \text{kg} \times \text{m}^2$ $J_{ext} = 0{,}7\ \text{kg} \times \text{m}^2$

3.2.5 Duty type S5 – Intermittent periodic duty with electric braking [2)]

A sequence of identical duty cycles, each cycle consisting of a starting time, a time of operation at constant load, a time of electric braking and a time at rest and de-energized, see figure 5.

[2)] Periodic duty implies that thermal equilibrium is not reached during the time on load.

L'abréviation appropriée est S5, suivi des valeurs du facteur de marche, du moment d'inertie du moteur (J_M) et du moment d'inertie de la charge (J_{ext}), tous deux rapportés à l'arbre du moteur.

Exemple: S5 25 % $J_M = 0{,}15\ kg \times m^2$ $J_{ext} = 0{,}7\ kg \times m^2$

3.2.6 Service type S6 – Service ininterrompu périodique à charge intermittente [2)]

Suite de cycles de service identiques comprenant chacun un temps de fonctionnement à charge constante et un temps de fonctionnement à vide. Il n'y a pas de temps de repos, voir figure 6.

L'abréviation appropriée est S6, suivi de la valeur du facteur de marche.

Exemple: S6 40 %

3.2.7 Service type S7 – Service ininterrompu périodique à freinage électrique [2)]

Suite de cycles de service identiques comprenant chacun un temps de démarrage, un temps de fonctionnement à charge constante et un temps de freinage électrique. Il n'y a pas de temps de repos, voir figure 7.

L'abréviation appropriée est S7 suivi des valeurs du moment d'inertie du moteur (J_M) et du moment d'inertie de la charge (J_{ext}), tous deux rapportés à l'arbre du moteur.

Exemple: S7 $J_M = 0{,}4\ kg \times m^2$ $J_{ext} = 7{,}5\ kg \times m^2$

3.2.8 Service type S8 – Service ininterrompu périodique à changements liés de charge et de vitesse [2)]

Suite de cycles de service identiques comprenant chacun un temps de fonctionnement à charge constante correspondant à une vitesse de rotation prédéterminée, suivie d'un ou plusieurs temps de fonctionnement à d'autres charges constantes correspondant à différentes vitesses de rotation (réalisées par exemple par changement du nombre de pôles dans le cas des moteurs à induction). Il n'y a pas de temps de repos (voir figure 8).

L'abréviation appropriée est S8 suivi des valeurs du moment d'inertie du moteur (J_M) et du moment d'inertie de la charge (J_{ext}), tous deux rapportés à l'arbre du moteur, de même que de la charge, de la vitesse et du facteur de marche pour chacun des régimes caractérisés par une vitesse.

Exemple: S8 $J_M = 0{,}5\ kg \times m^2$ $J_{ext} = 6\ kg \times m^2$

16 kW	740 min^{-1}	30 %
40 kW	1 460 min^{-1}	30 %
25 kW	980 min^{-1}	40 %

3.2.9 Service type S9 – Service à variations non périodiques de charge et de vitesse

Service dans lequel généralement la charge et la vitesse ont une variation non périodique dans la plage de fonctionnement admissible. Ce service inclut fréquemment des surcharges appliquées qui peuvent être largement supérieures à la charge de référence (voir figure 9).

L'abréviation appropriée est S9.

[2)] Un service type périodique implique que l'équilibre thermique n'est pas atteint pendant la période de charge.

The appropriate abbreviation is S5, followed by the cyclic duration factor, the moment of inertia of the motor (J_M) and the moment of inertia of the load (J_{ext}), both referred to the motor shaft.

Example: S5 25 % $J_M = 0{,}15\ kg \times m^2$ $J_{ext} = 0{,}7\ kg \times m^2$

3.2.6 Duty type S6 – Continuous-operation periodic duty [2)]

A sequence of identical duty cycles, each cycle consisting of a time of operation at constant load and a time of operation at no-load. There is no time at rest and de-energized, see figure 6.

The appropriate abbreviation is S6, followed by the cyclic duration factor.

Example: S6 40 %

3.2.7 Duty type S7 – Continuous-operation periodic duty with electric braking [2)]

A sequence of identical duty cycles, each cycle consisting of a starting time, a time of operation at constant load and a time of electric braking. There is no time at rest and de-energized, see figure 7.

The appropriate abbreviation is S7, followed by the moment of inertia of the motor (J_M) and the moment of inertia of the load (J_{ext}), both referred to the motor shaft.

Example: S7 $J_M = 0{,}4\ kg \times m^2$ $J_{ext} = 7{,}5\ kg \times m^2$

3.2.8 Duty type S8 – Continuous-operation periodic duty with related load/speed changes [2)]

A sequence of identical duty cycles, each cycle consisting of a time of operation at constant load corresponding to a predetermined speed of rotation, followed by one or more times of operation at other constant loads corresponding to different speeds of rotation (carried out, for example, by means of a change in the number of poles in the case of induction motors). There is no time at rest and de-energized (see figure 8).

The appropriate abbreviation is S8, followed by the moment of inertia of the motor (J_M) and the moment of inertia of the load (J_{ext}), both referred to the motor shaft, together with the load, speed and cyclic duration factor for each speed condition.

Example:	S8 $J_M = 0{,}5\ kg \times m^2$	$J_{ext} = 6\ kg \times m^2$	16 kW	740 min^{-1}	30 %
			40 kW	1 460 min^{-1}	30 %
			25 kW	980 min^{-1}	40 %

3.2.9 Duty type S9 – Duty with non-periodic load and speed variations

A duty in which generally load and speed vary non-periodically within the permissible operating range. This duty includes frequently applied overloads that may greatly exceed the reference load (see figure 9).

The appropriate abbreviation is S9.

---

2) Periodic duty implies that thermal equilibrium is not reached during the time on load.

Pour ce service type, une charge constante, judicieusement choisie et basée sur le service type S1, est prise comme valeur de référence («P_{ref}» dans la figure 9) pour la notion de surcharge.

3.2.10 Service type S10 – Service avec charges constantes distinctes

Service comprenant au plus quatre valeurs distinctes de charges (ou charges équivalentes), chaque charge étant maintenue pendant une durée suffisante pour permettre à la machine d'atteindre l'équilibre thermique, voir figure 10. La charge minimale pendant un cycle de service peut avoir la valeur zéro (fonctionnement à vide ou temps de repos).

L'abréviation appropriée est S10, suivi des valeurs réduites (p.u.) $p/\Delta t$ pour les différentes charges et leurs durées respectives, et de la valeur réduite (p.u.) TL pour l'espérance de vie thermique relative du système d'isolation. La valeur de référence pour l'espérance de vie thermique est l'espérance de vie thermique aux caractéristiques assignées pour service continu et aux limites admissibles d'échauffement basées sur le service type S1. Pour un temps de repos, la charge doit être indiquée par la lettre r.

Exemple: S10 $p/\Delta t$ = 1,1/0,4; 1/0,3; 0,9/0,2; r/0,1 TL = 0,6

Il convient d'arrondir la valeur de TL au plus proche multiple de 0,05. L'annexe A donne des indications sur la signification de ce paramètre et la détermination de sa valeur.

Pour ce service type, une charge constante, judicieusement choisie et basée sur le service type S1, doit être prise comme valeur de référence («P_{ref}» dans la figure 10) pour les charges distinctes.

NOTE Les valeurs distinctes de charges seront habituellement des charges équivalentes obtenues par intégration en fonction du temps. Il n'est pas nécessaire que chaque cycle de charge soit exactement le même, à condition que chaque charge à l'intérieur d'un cycle soit appliquée pendant une période suffisante pour que l'équilibre thermique soit atteint et que chaque cycle de charge puisse être intégré pour donner la même espérance de vie thermique relative.

Section 4: Caractéristiques assignées

4.1 Attribution des caractéristiques assignées

Les caractéristiques assignées, définies en 2.2, doivent être attribuées par le constructeur. En attribuant les caractéristiques assignées, le constructeur doit choisir l'une des classes de caractéristiques assignées définies de 4.2.1 à 4.2.6. La valeur de la puissance assignée doit être suivie par la désignation d'un service. Si aucune désignation n'est stipulée, les caractéristiques assignées pour service continu sont applicables.

Quand des composants auxiliaires (tels que des inductances, des capacités, etc.) sont insérés par le fabricant en tant qu'éléments de la machine, les valeurs assignées doivent se rapporter aux bornes d'alimentation de l'ensemble complet.

NOTE Cela ne s'applique pas aux transformateurs de puissance connectés entre la machine et l'alimentation.

Une attention spéciale est demandée lors de l'attribution de caractéristiques assignées à des machines alimentées par, ou alimentant, des convertisseurs statiques. La CEI 60034-17 donne des conseils pour le cas des moteurs à induction à cage couverts par la CEI 60034-12.

For this duty type a constant load appropriately selected and based on duty type S1 is taken as the reference value ("P_{ref}" in figure 9) for the overload concept.

3.2.10 Duty type S10 – Duty with discrete constant loads

A duty consisting of not more than four discrete values of load (or equivalent loading), each value being maintained for sufficient time to allow the machine to reach thermal equilibrium, see figure 10. The minimum load within a duty cycle may have the value zero (no-load or rest and de-energized).

The appropriate abbreviation is S10, followed by the p.u. quantities $p/\Delta t$ for the respective load and its duration and the p.u. quantity TL for the relative thermal life expectancy of the insulation system. The reference value for the thermal life expectancy is the thermal life expectancy at rating for continuous running duty and permissible limits of temperature rise based on duty type S1. For a time at rest and de-energized, the load shall be indicated by the letter r.

Example: S10 $p/\Delta t$ = 1,1/0,4; 1/0,3; 0,9/0,2; r/0,1 TL = 0,6

The value of TL should be rounded off to the nearest multiple of 0,05. Advice concerning the significance of this parameter and the derivation of its value is given in annex A.

For this duty type a constant load appropriately selected and based on duty type S1 shall be taken as the reference value ('P_{ref}' in figure 10) for the discrete loads.

NOTE The discrete values of load will usually be equivalent loading based on integration over a period of time. It is not necessary that each load cycle be exactly the same, only that each load within a cycle be maintained for sufficient time for thermal equilibrium to be reached, and that each load cycle be capable of being integrated to give the same relative thermal life expectancy.

Section 4: Rating

4.1 Assignment of rating

The rating, as defined in 2.2, shall be assigned by the manufacturer. In assigning the rating the manufacturer shall select one of the classes of rating defined in 4.2.1 to 4.2.6. The designation of the class of rating shall be written after the rated output. If no designation is stated, rating for continuous running duty applies.

When accessory components (such as reactors, capacitors, etc.) are connected by the manufacturer as part of the machine, the rated values shall refer to the supply terminals of the whole arrangement.

NOTE This does not apply to power transformers connected between the machine and the supply.

Special considerations are required when assigning ratings to machines fed from or supplying static converters. IEC 60034-17 gives guidance for the case of cage induction motors covered in IEC 60034-12.

4.2 Classes de caractéristiques assignées

4.2.1 Caractéristiques assignées pour service continu

Caractéristiques assignées auxquelles la machine peut fonctionner pendant une durée illimitée et conformément aux prescriptions de la présente norme.

Cette classe de caractéristiques assignées correspond au service type S1 et est désignée comme le service type S1.

4.2.2 Caractéristiques assignées pour service temporaire

Caractéristiques assignées auxquelles la machine peut fonctionner pendant une durée limitée, en démarrant à la température ambiante et conformément aux prescriptions de la présente norme.

Cette classe de caractéristiques assignées correspond au service type S2 et est désignée comme le service type S2.

4.2.3 Caractéristiques assignées pour service périodique

Caractéristiques assignées auxquelles la machine peut fonctionner suivant des cycles de service, conformément aux prescriptions de la présente norme.

Cette classe de caractéristiques assignées correspond à l'un des services types périodiques S3 à S8 et est désignée comme le service type correspondant.

Sauf spécifications contraires, la durée d'un cycle de service doit être de 10 min et le facteur de marche doit avoir l'une des valeurs suivantes:

15 %, 25 %, 40 %, 60 %.

4.2.4 Caractéristiques assignées pour service non périodique

Caractéristiques assignées auxquelles la machine peut fonctionner de façon non périodique, conformément aux prescriptions de la présente norme.

Cette classe de caractéristiques assignées correspond au service type non périodique S9 et est désignée comme le service type S9.

4.2.5 Caractéristiques assignées pour service avec charges constantes distinctes

Caractéristiques assignées auxquelles la machine peut fonctionner avec l'association des charges du service type S10, pendant une durée illimitée tout en satisfaisant aux prescriptions de la présente norme. La charge maximale admissible dans un cycle doit prendre en considération tous les éléments de la machine, par exemple le système d'isolation en ce qui concerne la validité de la loi exponentielle pour l'espérance de vie thermique relative, les paliers en ce qui concerne la température, d'autres éléments en ce qui concerne la dilatation thermique. Sauf spécifications dans d'autres normes de la CEI, la charge maximale ne dépassera pas 1,2 fois la valeur de la charge basée sur le service type S1. La charge minimale peut avoir la valeur zéro quand la machine fonctionne à vide ou est au repos. Des informations concernant l'application de cette classe de caractéristiques assignées sont données en annexe A.

Cette classe de caractéristiques assignées correspond au service type S10 et est désignée comme le service type S10.

4.2 Classes of rating

4.2.1 Rating for continuous running duty

A rating at which the machine may be operated for an unlimited period, while complying with the requirements of this standard.

This class of rating corresponds to duty type S1 and is designated as for the duty type S1.

4.2.2 Rating for short-time duty

A rating at which the machine may be operated for a limited period, starting at ambient temperature, while complying with the requirements of this standard.

This class of rating corresponds to duty type S2 and is designated as for the duty type S2.

4.2.3 Rating for periodic duty

A rating at which the machine may be operated on duty cycles, while complying with the requirements of this standard.

This class of rating corresponds to one of the periodic duty types S3 to S8 and is designated as for the corresponding duty type.

Unless otherwise specified, the duration of a duty cycle shall be 10 min and the cyclic duration factor shall be one of the following values:

15 %, 25 %, 40 %, 60 %.

4.2.4 Rating for non-periodic duty

A rating at which the machine may be operated non-periodically while complying with the requirements of this standard.

This class of rating corresponds to the non-periodic duty type S9 and is designated as for the duty type S9.

4.2.5 Rating for duty with discrete constant loads

A rating at which the machine may be operated with the associated loads of duty type S10 for an unlimited period of time while complying with the requirements of this standard. The maximum permissible load within one cycle shall take into consideration all parts of the machine, e.g. the insulation system regarding the validity of the exponential law for the relative thermal life expectancy, bearings with respect to temperature, other parts with respect to thermal expansion. Unless specified in other relevant IEC standards, the maximum load shall not exceed 1,2 times the value of the load based on duty type S1. The minimum load may have the value zero, the machine operating at no-load or being at rest and de-energized. Considerations for the application of this class of rating are given in annex A.

This class of rating corresponds to the duty type S10 and is designated as for the duty type S10.

NOTE D'autres normes appropriées de la CEI peuvent spécifier la charge maximale en termes de limitation de la température (ou d'échauffement) d'enroulement au lieu d'une valeur relative de la charge basée sur le service type S1.

4.2.6 Caractéristiques assignées pour charge équivalente

Caractéristiques assignées auxquelles, à des fins d'essais, la machine peut fonctionner à charge constante jusqu'à ce que l'équilibre thermique soit atteint et qui conduisent au même échauffement de l'enroulement statorique qu'à la fin de l'essai en services type.

NOTE Pour déterminer des caractéristiques assignées du type équivalent, il convient de prendre en compte les charge, vitesse et refroidissement variables du cycle de service.

Le cas échéant, cette classe de caractéristiques assignées est désignée «équ».

4.3 Choix d'une classe de caractéristiques assignées

Une machine construite en vue d'un usage général doit avoir des caractéristiques assignées pour service continu et être capable de fonctionner en service type S1.

Si le service n'a pas été spécifié par l'acheteur, le service type S1 est applicable et les caractéristiques assignées doivent être des caractéristiques assignées pour service continu.

Lorsqu'une machine est prévue pour des caractéristiques assignées pour service temporaire, les caractéristiques assignées doivent être basées sur le service type S2, voir 3.2.2.

Lorsqu'une machine est prévue pour fonctionner à des charges variables ou des charges comprenant un temps de fonctionnement à vide ou des temps pendant lesquelles la machine est à l'état de repos, les caractéristiques assignées doivent être des caractéristiques assignées pour service périodique basées sur un service type choisi parmi les services types S3 à S8, voir 3.2.3 à 3.2.8.

Lorsqu'une machine est prévue pour fonctionner de façon non périodique à des charges variables à des vitesses variables, y compris à des surcharges, les caractéristiques assignées doivent être des caractéristiques assignées pour service non périodique basées sur le service type S9, voir 3.2.9.

Lorsqu'une machine est prévue pour fonctionner à des charges constantes distinctes comprenant des temps de surcharge ou des temps de marche à vide (ou de repos) les caractéristiques assignées doivent être des caractéristiques assignées pour service avec charges constantes distinctes basées sur le service type S10, voir 3.2.10.

4.4 Attribution de la puissance à une classe de caractéristiques assignées

Dans la détermination des caractéristiques assignées:

Pour les services types S1 à S8, la ou les valeurs spécifiées des charges constantes doivent être les puissances assignées; voir 3.2.1 à 3.2.8.

Pour les services types S9 et S10, la valeur de référence de la charge basée sur le service type S1 doit être prise comme puissance assignée, voir 3.2.9 et 3.2.10.

4.5 Puissance assignée

4.5.1 Génératrices à courant continu

La puissance assignée est la puissance aux bornes; elle doit être exprimée en watts (W).

NOTE Other relevant IEC standards may specify the maximum load in terms of limiting winding temperature (or temperature rise) instead of per unit load based on duty type S1.

4.2.6 Rating for equivalent loading

A rating, for test purposes, at which the machine may be operated at constant load until thermal equilibrium is reached and which results in the same stator winding temperature rise as at the end of the test on the specified duty type.

NOTE The determination of an equivalent rating should take account of the varying load, speed and cooling of the duty cycle.

This class of rating, if applied, is designated 'equ'.

4.3 Selection of a class of rating

A machine manufactured for general purpose shall have a rating for continuous running duty and be capable of performing duty type S1.

If the duty has not been specified by the purchaser, duty type S1 applies and the rating assigned shall be a rating for continuous running duty.

When a machine is intended to have a rating for short-time duty, the rating shall be based on duty type S2, see 3.2.2.

When a machine is intended to supply varying loads or loads including a time of no-load or times where the machine will be in a state of rest and de-energized, the rating shall be a rating for periodic duty based on a duty type selected from duty types S3 to S8, see 3.2.3 to 3.2.8.

When a machine is intended non-periodically to supply variable loads at variable speeds, including overloads, the rating shall be a rating for non-periodic duty based on duty type S9, see 3.2.9.

When a machine is intended to supply discrete constant loads including times of overload or times of no-load (or rest and de-energized) the rating shall be a rating with discrete constant loads based on duty type S10, see 3.2.10.

4.4 Allocation of outputs to class of rating

In the determination of the rating:

For duty types S1 to S8, the specified value(s) of the constant load(s) shall be the rated output(s), see 3.2.1 to 3.2.8.

For duty types S9 and S10, the reference value of the load based on duty type S1 shall be taken as the rated output, see 3.2.9 and 3.2.10.

4.5 Rated output

4.5.1 DC generators

The rated output is the output at the terminals and shall be expressed in watts (W).

4.5.2 Alternateurs

La puissance assignée est la puissance électrique apparente aux bornes; elle doit être exprimée en voltampères (VA), complétée par l'indication du facteur de puissance.

Le facteur de puissance assigné des alternateurs synchrones doit être de 0,8 surexcité, sauf spécification contraire de l'acheteur.

4.5.3 Moteurs

La puissance assignée est la puissance mécanique disponible sur l'arbre; elle doit être exprimée en watts (W).

NOTE Il est d'usage dans de nombreux pays d'exprimer aussi la puissance mécanique disponible sur l'arbre en chevaux (1 h.p. est équivalent à 745,7 W; 1 ch est équivalent à 736 W).

4.5.4 Compensateurs synchrones

La puissance assignée est la puissance réactive aux bornes; elle doit être exprimée en voltampères réactifs (var) soit en régime sous-excité soit en régime surexcité.

4.6 Tension assignée

4.6.1 Génératrices de courant continu

Pour les génératrices de courant continu prévues pour fonctionner dans une plage de tensions d'étendue relativement faible, la puissance assignée et le courant assigné doivent, sauf spécification contraire, être applicables à la limite supérieure de la plage de tensions, voir également 6.3.

4.6.2 Alternateurs

Pour les alternateurs prévus pour fonctionner dans une plage de tensions d'étendue relativement faible, la puissance assignée et le facteur de puissance assigné doivent, sauf spécification contraire, être applicables à toute tension de la plage (voir également 6.3).

4.7 Coordination des tensions et des puissances

En pratique on ne construit pas des machines de toutes caractéristiques assignées et de toutes tensions assignées. En général, pour les machines à courant alternatif, en se basant sur des considérations de conception et de fabrication, les tensions assignées préférables supérieures à 1 kV sont indiquées ci-dessus, en fonction des puissances assignées.

Tension assignée kV	**Puissance assignée minimale** kW (ou kVA)
$1{,}0 < U_N \leq 3{,}0$	100
$3{,}0 < U_N \leq 6{,}0$	150
$6{,}0 < U_N \leq 11{,}0$	800
$11{,}0 < U_N \leq 15{,}0$	2 500

4.5.2 AC generators

The rated output is the apparent power at the terminals and shall be expressed in volt-amperes (VA) together with the power factor.

The rated power factor for synchronous generators shall be 0,8 lagging (over-excited), unless otherwise specified by the purchaser.

4.5.3 Motors

The rated output is the mechanical power available at the shaft and shall be expressed in watts (W).

NOTE It is the practice in some countries for the mechanical power available at the shafts of motors to be expressed in horsepower (1 h.p. is equivalent to 745,7 W; 1 ch (cheval or metric horsepower) is equivalent to 736 W).

4.5.4 Synchronous condensers

The rated output is the reactive power at the terminals and shall be expressed in volt-amperes reactive (var) in either leading (under-excited) or lagging (over-excited) conditions.

4.6 Rated voltage

4.6.1 DC generators

For d.c. generators intended to operate over a relatively small range of voltage, the rated output and current shall apply at the highest voltage of the range, unless otherwise specified, see also 6.3.

4.6.2 AC generators

For a.c. generators intended to operate over a relatively small range of voltage, the rated output and power factor shall apply at any voltage within the range, unless otherwise specified (see also 6.3).

4.7 Coordination of voltages and outputs

It is not practical to build machines of all ratings for all rated voltages. In general, for a.c. machines, based on design and manufacturing considerations, preferred voltage ratings above 1 kV in terms of rated output are as follows:

Rated voltage kV	**Minimum rated output** kW (or kVA)
$1{,}0 < U_N \leq 3{,}0$	100
$3{,}0 < U_N \leq 6{,}0$	150
$6{,}0 < U_N \leq 11{,}0$	800
$11{,}0 < U_N \leq 15{,}0$	2 500

4.8 Machines à plus d'un ensemble de caractéristiques assignées

Pour les machines prévues pour plus d'un ensemble de caractéristiques assignées, la machine doit être conforme, à tous points de vue, à la présente norme pour chaque ensemble de caractéristiques assignées.

Pour les moteurs à plusieurs vitesses, des caractéristiques assignées doivent être attribuées pour chaque vitesse.

Quand une grandeur assignée (puissance, tension, vitesse, etc.) peut avoir plusieurs valeurs ou varier constamment entre deux limites, les caractéristiques assignées doivent être attribuées à ces valeurs ou limites. Cette disposition ne s'applique ni aux variations de tension et de fréquence en fonctionnement définies en 6.3, ni au montage étoile-triangle pour le démarrage.

Section 5: Conditions de fonctionnement sur site

5.1 Généralités

Sauf spécifications contraires, les machines doivent être appropriées aux conditions de fonctionnement sur site données ci-dessous. Pour des conditions de fonctionnement sur site différentes de ces valeurs, des corrections sont données en 7.

5.2 Altitude

L'altitude ne doit pas dépasser 1 000 m au-dessus du niveau de la mer.

5.3 Température maximale de l'air ambiant

La température de l'air ambiant ne doit pas dépasser 40 °C.

5.4 Température minimale de l'air ambiant

La température de l'air ambiant ne doit pas être inférieure à –15 °C, quelle que soit la machine.

Pour une machine possédant un des éléments suivants:

a) une puissance assignée supérieure à 3 300 kW (ou kVA) par 1 000 min^{-1};
b) une puissance assignée inférieure à 600 W (ou VA);
c) un collecteur;
d) un palier à coussinet;
e) l'eau comme fluide de refroidissement primaire ou secondaire,

la température minimale de l'air ambiant ne doit pas être inférieure à 0 °C.

5.5 Température de l'eau de refroidissement

La température de l'eau de refroidissement à l'entrée d'une machine ou d'un échangeur de chaleur ne doit pas dépasser +25 °C ou être inférieure à +5 °C.

4.8 Machines with more than one rating

For machines with more than one rating, the machine shall comply with this standard in all respects at each rating.

For multi-speed motors, a rating shall be assigned for each speed.

When a rated quantity (output, voltage, speed, etc.) may assume several values or vary continuously within two limits, the rating shall be stated at these values or limits. This provision does not apply to voltage and frequency variations during operation as defined in 6.3 or to star-delta connections intended for starting.

Section 5: Site operating conditions

5.1 General

Unless otherwise specified machines shall be suitable for the following site operation conditions. For site operating conditions deviating from those values corrections are given in 7.

5.2 Altitude

The altitude shall not exceed 1 000 m above sea-level.

5.3 Maximum ambient air temperature

The ambient air temperature shall not exceed 40 °C.

5.4 Minimum ambient air temperature

The ambient air temperature shall not be less than –15 °C for any machine.

For a machine with any of the following:

a) rated output greater than 3 300 kW (or kVA) per 1 000 min^{-1};
b) rated output less than 600 W (or VA);
c) a commutator;
d) a sleeve bearing;
e) water as a primary or secondary coolant,

the ambient air temperature shall not be less than 0 °C.

5.5 Water coolant temperature

The water coolant temperature at the inlet to a machine or heat exchanger shall not exceed +25 °C nor be less than +5 °C.

5.6 Stockage et transport

Quand des températures inférieures à celles spécifiées en 5.4 sont susceptibles de se produire durant le transport, le stockage ou après installation, l'acheteur doit informer le constructeur et spécifier la température minimale prévue.

5.7 Pureté de l'hydrogène de refroidissement

Les machines refroidies à l'hydrogène doivent être capables de fonctionner à la puissance assignée dans les conditions assignées avec un fluide de refroidissement contenant au moins 95 % d'hydrogène en volume.

NOTE Pour des raisons de sécurité, la teneur en hydrogène devra toujours être maintenue à 90 % ou davantage, en admettant que l'autre gaz entrant dans le mélange soit l'air.

Pour calculer le rendement conformément à la CEI 60034-2, la composition normalisée du mélange gazeux doit être de 98 % d'hydrogène et 2 % d'air en volume, à des valeurs spécifiées de pression et de température du fluide refroidi, sauf accord contraire. Les pertes par ventilation doivent être calculées pour la densité correspondante.

Section 6: Conditions de fonctionnement électriques

6.1 Alimentation électrique

Pour les machines triphasées à courant alternatif, 50 Hz ou 60 Hz, destinées à être directement reliées à un réseau de distribution ou d'utilisation, les tensions assignées doivent être déduites des tensions nominales données dans la CEI 60038.

NOTE Pour les machines à courant alternatif de forte puissance à haute tension, les tensions peuvent être choisies pour l'obtention de caractéristiques de fonctionnement optimales.

Pour les moteurs à courant alternatif alimentés par convertisseurs statiques, ces restrictions sur la tension, la fréquence et la forme d'onde ne sont pas applicables. Dans ce cas le choix des tensions assignées doit se faire par accord.

6.2 Forme et symétrie des tensions et des courants

6.2.1 Moteurs à courant alternatif

6.2.1.1 Les moteurs à courant alternatif ayant parmi leur caractéristiques assignées le fonctionnement sur une alimentation à fréquence fixe, alimentée par un alternateur (localement ou à travers un réseau de distribution) doivent pouvoir fonctionner sous une tension d'alimentation dont le facteur harmonique de tension (HVF) est inférieur ou égal à

0,02 pour les moteurs monophasés et les moteurs triphasés, y compris les moteurs synchrones mais en excluant les moteurs de concept N (voir la CEI 60034-12), sauf déclaration contraire du constructeur.

0,03 pour les moteurs de conception N.

Le HVF doit être calculé à partir de la formule suivante:

$$\mathrm{HVF} = \sqrt{\sum \frac{u_n^2}{n}}$$

où

u_n est la valeur réduite (p.u.) de l'harmonique de tension (par rapport à la tension assignée U_N);

5.6 Storage and transport

When temperatures lower than specified in 5.4 are expected during transportation, storage, or after installation, the purchaser shall inform the manufacturer and specify the expected minimum temperature.

5.7 Purity of hydrogen coolant

Hydrogen cooled machines shall be capable of operating at rated output under rated conditions with a coolant containing not less than 95 % hydrogen by volume.

NOTE For safety reasons, the hydrogen content should at all times be maintained at 90 % or more, it being assumed that the other gas in the mixture is air.

For calculating efficiency in accordance with IEC 60034-2, the standard composition of the gaseous mixture shall be 98 % hydrogen and 2 % air by volume, at the specified values of pressure and temperature of the re-cooled gas, unless otherwise agreed. Windage losses shall be calculated at the corresponding density.

Section 6: Electrical operating conditions

6.1 Electrical supply

For three-phase a.c. machines, 50 Hz or 60 Hz, intended to be directly connected to distribution or utilisation systems, the rated voltages shall be derived from the nominal voltages given in IEC 60038.

NOTE For large high-voltage a.c. machines, the voltages may be selected for optimum performance.

For a.c. motors supplied from static converters these restrictions on voltage, frequency and waveform do not apply. In this case the rated voltages shall be selected by agreement.

6.2 Form and symmetry of voltages and currents

6.2.1 AC motors

6.2.1.1 AC motors rated for use on a power supply of fixed frequency, supplied from an a.c. generator (whether local or via a supply network) shall be suitable for operation on a supply voltage having a harmonic voltage factor (HVF) not exceeding

0,02 for single phase motors and three phase motors, including synchronous motors but excluding motors of design N (see IEC 60034-12), unless the manufacturer declares otherwise.

0,03 for design N motors.

The HVF shall be computed by using the following formula:

$$\mathrm{HVF} = \sqrt{\sum \frac{u_n^2}{n}}$$

where

u_n is the per unit value of the harmonic voltage (referred to rated voltage U_N);

n est le rang de l'harmonique (non divisible par trois dans le cas d'un moteur à courant alternatif triphasé).

Généralement, il suffit de considérer les harmoniques de rang $n \leq 13$.

Les moteurs triphasés à courant alternatif doivent être appropriés au fonctionnement sur un système de tensions dont la composante inverse ne dépasse pas 1 % de la composante directe pendant une longue période, ou 1,5 % pendant une courte période n'excédant pas quelques minutes, et dont la composante homopolaire n'excède pas 1 % de la composante directe.

Si les limites des valeurs du HVF et de la composante inverse et homopolaire se trouvent atteintes simultanément en service à la charge assignée, cela ne doit pas conduire à une température nuisible dans le moteur et il est recommandé que le dépassement d'échauffement ou de température qui en résulte par rapport aux limites spécifiées dans cette norme n'excède pas environ 10 K.

NOTE A proximité de fortes charges monophasées (par exemple fours à induction) et dans les zones rurales, en particulier dans le cas de réseau mixte industriel et domestique, l'alimentation peut être déformée au-delà des limites fixées ci-dessus. Une telle situation nécessite de prendre des dispositions spéciales.

6.2.1.2 Les moteurs à courant alternatif alimentés par convertisseurs statiques doivent supporter un taux supérieur d'harmoniques de la tension d'alimentation; voir la CEI 60034-17 pour le cas des moteurs à cage ouverts par la CEI 60034-12.

NOTE Si la tension d'alimentation est notablement non sinusoïdale, par exemple dans le cas d'alimentation par convertisseur statique, la valeur efficace de la forme d'onde totale et celle de l'onde fondamentale sont toutes deux appropriées lors de la détermination des caractéristiques de fonctionnement d'une machine à courant alternatif.

6.2.2 Alternateurs

Les alternateurs doivent être appropriés à l'alimentation de circuits qui sont pratiquement non-déformants et pratiquement équilibrés, c'est-à-dire, si, alimentés par une tension sinusoïdale, aucune des valeurs instantanées du courant ne diffère de la valeur instantanée correspondante de l'onde fondamentale de plus de 5 % de l'amplitude de cette dernière et si, alimentés par un système de tensions symétrique, ni la composante inverse, ni la composante homopolaire du système de courants ne dépasse 5 % de la composante directe.

Si les limites de déformation et d'équilibre se trouvent atteintes simultanément en service à la charge assignée, cela ne doit pas conduire à une température nuisible dans l'alternateur et il est recommandé que le dépassement d'échauffement ou de température qui en résulte par rapport aux limites spécifiées dans cette norme n'excède pas environ 10 K.

6.2.3 Machines synchrones

Sauf spécification contraire, les machines synchrones triphasées doivent être capables de fonctionner en permanence sur un réseau dissymétrique tel que, aucun des courants de phase de ne dépassant le courant assigné, le rapport de la composante inverse du système de courants (I_2) au courant assigné (I_N) ne dépasse pas les valeurs du tableau 1, et de fonctionner, en cas de défaut à des valeurs du produit de $(I_2/I_N)^2$ par le temps (t) ne dépassant pas les valeurs du tableau 1.

n is the order of harmonic (not divisible by three in the case of three-phase a.c. motors).

Usually it is sufficient to consider harmonic orders $n \leq 13$.

Three-phase a.c. motors shall be suitable for operation on a three-phase voltage system having a negative-sequence component not exceeding 1 % of the positive-sequence component over a long period, or 1,5 % for a short period not exceeding a few minutes, and a zero-sequence component not exceeding 1 % of the positive-sequence component.

Should the limiting values of the HVF and of the negative-sequence and zero-sequence components occur simultaneously in service at the rated load, this shall not lead to any deleterious temperature in the motor and it is recommended that the excess resulting temperature rise or temperature related to the limits specified in this standard should be not more than approximately 10 K.

NOTE In the vicinity of large single-phase loads (e.g. induction furnaces), and in rural areas particularly on mixed industrial and domestic systems, supplies may be distorted beyond the limits set out above. Special arrangements will then be necessary.

6.2.1.2 AC motors supplied from static converters have to tolerate higher harmonic contents of the supply voltage, see IEC 60034-17 for the case of cage motors within the scope of IEC 60034-12.

NOTE When the supply voltage is significantly non-sinusoidal e.g. from static converters, the r.m.s. value of the total waveform and of the fundamental are both relevant in determining the performance of an a.c. machine.

6.2.2 AC generators

AC generators shall be suitable for supplying circuits which are virtually non-deforming and virtually balanced, that is to say, when supplied by a sinusoidal voltage, none of the instantaneous values of the current differ from the corresponding instantaneous value of the fundamental by more than 5 % of the amplitude of the latter, and when supplied by a balanced system of voltages, neither the negative-sequence component nor the zero-sequence component of the system of currents exceeds 5 % of the positive-sequence component.

Should the limits of deformation and balance occur simultaneously in service at the rated load, this shall not lead to any deleterious temperature in the generator and it is recommended that the excess resulting temperature rise or temperature related to the limits specified in this standard should be not more than approximately 10 K.

6.2.3 Synchronous machines

Unless otherwise specified, three-phase synchronous machines shall be capable of operating continuously on an unbalanced system such that, with none of the phase currents exceeding the rated current, the ratio of the negative-sequence component of current (I_2) to the rated current (I_N) does not exceed the values in table 1 and under fault conditions shall be capable of operation with the product of $(I_2/I_N)^2$ and time (t) not exceeding the values in table 1.

Tableau 1 – Conditions de fonctionnement déséquilibrées pour les machines synchrones

Point	Type de machine	Valeur maximale I_2/I_N pour un fonctionnement permanent	Valeur maximale $(I_2/I_N)^2 \times t$ en secondes pour fonctionnement en régime de défaut
	Machines à pôles saillants		
1	Enroulements à refroidissement indirect		
	moteurs	0,1	20
	génératrices	0,08	20
	compensateurs synchrones	0,1	20
2	Enroulements à refroidissement direct (refroidissement interne) au stator et/ou à l'inducteur		
	moteurs	0,08	15
	génératrices	0,05	15
	compensateurs synchrones	0,08	15
	Machines synchrones à rotor lisse		
3	Enroulements rotor à refroidissement indirect		
	par air	0,1	15
	par hydrogène	0,1	10
4	Enroulements rotor à refroidissement direct (refroidissement interne)		
	≤ 350 MVA	0,08	8
	> 350 ≤ 900 MVA	Voir note 1	Voir note 2
	> 900 ≤ 1 250 MVA	Voir note 1	5
	> 1 250 ≤ 1 600 MVA	0,05	5

NOTE 1 Pour ces machines, la valeur I_2/I_N est calculée comme suit:

$$\frac{I_2}{I_N} = 0{,}08 - \frac{S_N - 350}{3 \times 10^4}$$

NOTE 2 Pour ces machines, la valeur $(I_2/I_N)^2 \times t$, en secondes, est calculée comme suit:

$$(I_2/I_N)^2 \times t = 8 - 0{,}005\,45\,(S_N - 350)$$

où (dans les deux notes) S_N est la puissance apparente assignée en mégavoltampères.

6.2.4 Moteurs à courant continu alimentés par convertisseurs statiques de puissance

Dans le cas d'un moteur à courant continu alimenté par un convertisseur statique de puissance, la forme d'ondulation de la tension et du courant influent sur les caractéristiques de fonctionnement de la machine. Les pertes et l'échauffement vont s'accroître et la commutation sera plus difficile qu'avec un moteur à courant continu alimenté par une source de courant continu pur.

Table 1 – Unbalanced operating conditions for synchronous machines

Item	Machine type	Maximum I_2/I_N value for continuous operation	Maximum $(I_2/I_N)^2 \times t$ in seconds for operation under fault conditions
	Salient pole machines		
1	Indirect cooled windings		
	motors	0,1	20
	generators	0,08	20
	synchronous condensers	0,1	20
2	Direct cooled (inner cooled) stator and/or field windings		
	motors	0,08	15
	generators	0,05	15
	synchronous condensers	0,08	15
	Cylindrical rotor synchronous machines		
3	Indirect cooled rotor windings		
	air-cooled	0,1	15
	hydrogen-cooled	0,1	10
4	Direct cooled (inner cooled) rotor windings		
	≤350 MVA	0,08	8
	>350 ≤900 MVA	See note 1	See note 2
	>900 ≤1 250 MVA	See note 1	5
	>1 250 ≤1 600 MVA	0,05	5

NOTE 1 For these machines, the value of I_2/I_N is calculated as follows:

$$\frac{I_2}{I_N} = 0{,}08 - \frac{S_N - 350}{3 \times 10^4}$$

NOTE 2 For these machines, the value of $(I_2/I_N)^2 \times t$, in seconds is calculated as follows:

$$(I_2/I_N)^2 \times t = 8 - 0{,}005\,45\,(S_N - 350)$$

where in the two notes, S_N is the rated apparent power in megavoltamperes.

6.2.4 DC motors supplied from static power converters

In the case of a d.c. motor supplied from a static power converter, the pulsating voltage and current affect the performance of the machine. Losses and temperature rise will increase and the commutation is more difficult compared with a d.c. motor supplied from a pure d.c. power source.

En conséquence, pour les moteurs de puissance assignée supérieure à 5 kW destinés à être alimentés par un convertisseur statique de puissance, il est nécessaire de concevoir leur fonctionnement à partir d'une alimentation spécifiée et, si le constructeur du moteur le juge nécessaire, avec une inductance externe prévue pour réduire l'ondulation.

L'alimentation par convertisseur statique de puissance doit être caractérisée au moyen d'un code d'identification comme suit:

$$[\text{CCC} - U_{\text{aN}} - f - L\ ]$$

où

CCC est le code d'identification de connexion du convertisseur conformément à la CEI 60971;

U_{aN} est constitué de trois ou quatre chiffres indiquant la valeur assignée de la tension alternative aux bornes d'entrée du convertisseur, en volts;

f est constitué de deux chiffres indiquant la fréquence assignée aux bornes d'entrée, en hertz;

L est constitué de un, deux ou trois chiffres indiquant la valeur de l'inductance série à ajouter extérieurement au circuit d'induit du moteur, en millihenrys. Si cette valeur est égale à zéro, elle est omise.

Les moteurs de puissance assignée inférieure à égale à 5 kW, au lieu d'être liés à un type spécifique de convertisseur statique de puissance, peuvent être conçus pour une utilisation avec tout convertisseur statique de puissance, avec ou sans inductance extérieure, pourvu que la valeur assignée du facteur de forme pour lequel le moteur est conçu ne soit pas dépassée et que le niveau d'isolation du circuit d'induit du moteur soit adapté à la valeur assignée de la tension alternative aux bornes d'entrée du convertisseur statique de puissance.

Dans tous les cas, l'ondulation du courant fourni par le convertisseur statique de puissance est présumée être assez faible pour qu'il en résulte un facteur d'ondulation du courant inférieur à 0,1 aux conditions assignées.

6.3 Variations de tension et de fréquence en fonctionnement

Pour les machines à courant alternatif ayant parmi leurs caractéristiques assignées le fonctionnement sur une alimentation à fréquence fixe, alimentée par un alternateur (localement ou à travers un réseau de distribution), les combinaisons des variations de tension et de fréquence sont classées en zone A ou en zone B, conformément à la figure 11 pour les alternateurs et à la figure 12 pour les moteurs.

Pour les machines à courant continu reliées directement à une alimentation à courant continu normalement constante, les zones A et B s'appliquent uniquement aux tensions.

Une machine doit être capable d'assurer sa fonction principale comme spécifié au tableau 2 de façon continue à l'intérieur de la zone A, mais peut ne pas satisfaire complètement à ses caractéristiques de fonctionnement à tension et fréquence assignées (voir le point des caractéristiques assignées sur les figures 11 et 12), et présenter certains écarts. Les échauffements peuvent être supérieurs à ceux à tension et fréquence assignées.

Une machine doit être capable d'assurer sa fonction principale à l'intérieur de la zone B, mais peut présenter des écarts supérieurs à ceux de la zone A par rapport à ses caractéristiques de fonctionnement à tension et fréquence assignées. Les échauffements peuvent être supérieurs à ceux à tension et fréquence assignées et seront très probablement supérieurs à ceux de la zone A. Un fonctionnement prolongé à la périphérie de la zone B n'est pas recommandé.

It is necessary, therefore, for motors with a rated output exceeding 5 kW, intended for supply from a static power converter, to be designed for operation from a specified supply, and, if considered necessary by the motor manufacturer, for an external inductance to be provided for reducing the undulation.

The static power converter supply shall be characterized by means of an identification code, as follows:

$$[\text{CCC} - U_{\text{aN}} - f - L]$$

where

CCC is the identification code for converter connection according to IEC 60971;

U_{aN} consists of three or four digits indicating the rated alternating voltage at the input terminals of the converter, in volts;

f consists of two digits indicating the rated input frequency, in hertz;

L consists of one, two or three digits indicating the series inductance to be added externally to the motor armature circuit, in millihenrys. If this is zero, it is omitted.

Motors with rated output not exceeding 5 kW, instead of being tied to a specific type of static power converter, may be designed for use with any static power converter, with or without external inductance, provided that the rated form factor for which the motor is designed will not be surpassed and that the insulation level of the motor armature circuit is appropriate for the rated alternating voltage at the input terminals of the static power converter.

In all cases, the undulation of the static power converter output current is assumed to be so low as to result in a current ripple factor not higher than 0,1 at rated conditions.

6.3 Voltage and frequency variations during operation

For a.c. machines rated for use on a power supply of fixed frequency supplied from an a.c. generator (whether local or via a supply network), combinations of voltage variation and frequency variation are classified as being either zone A or zone B, in accordance with figure 11 for generators and synchronous condensers, and figure 12 for motors.

For d.c. machines, when directly connected to a normally constant d.c. bus, zones A and B apply only to the voltages.

A machine shall be capable of performing its primary function, as specified in table 2, continuously within zone A, but need not comply fully with its performance at rated voltage and frequency (see rating point in figures 11 and 12), and may exhibit some deviations. Temperature rises may be higher than at rated voltage and frequency.

A machine shall be capable of performing its primary function within zone B, but may exhibit greater deviations from its performance at rated voltage and frequency than in zone A. Temperature rises may be higher than at rated voltage and frequency and most likely will be higher than those in zone A. Extended operation at the perimeter of zone B is not recommended.

NOTE 1 Dans des applications et conditions de fonctionnement pratiques, une machine sera parfois sollicitée pour fonctionner à l'extérieur du périmètre de la zone A. Il est recommandé de limiter de tels écarts en valeur, durée et fréquence d'apparition. Si possible, il convient de prendre des mesures correctives dans un délai raisonnable, par exemple une réduction de puissance. De telles interventions peuvent éviter une réduction de la durée de vie de la machine due aux effets de la température.

NOTE 2 Les limites d'échauffement ou les limites de température conformes à la présente norme sont applicables au point des caractéristiques assignées et peuvent être progressivement dépassées si le point de fonctionnement s'écarte du point des caractéristiques assignées. Pour des conditions aux limites extrêmes de la zone A, les échauffements et températures dépassent habituellement d'environ 10 K les limites spécifiées dans la présente norme.

NOTE 3 Un moteur à courant alternatif ne démarrera à la limite inférieure de tension que si son couple de démarrage est approprié au couple résistant de la charge, mais cela ne constitue pas une exigence du présent article. Pour les caractéristiques de démarrage des moteurs de conception N, voir la CEI 60034-12.

Tableau 2 – Fonctions principales des machines

Point	Type de machine	Fonction principale
1	Alternateur, en excluant le point 5	Puissance assignée apparente (kVA), au facteur de puissance assigné s'il est à commande séparée
2	Moteur à courant alternatif, en excluant les points 3 et 5	Couple assigné (Nm)
3	Moteur synchrone en excluant le point 5	Couple assigné (Nm) avec l'excitation maintenant soit le courant d'excitation assigné, soit le facteur de puissance assigné, lorsque celui-ci peut être commandé séparément
4	Compensateur synchrone, en excluant le point 5	Puissance apparente assignée (kVA) à l'intérieur de la zone applicable à une génératrice sauf accord contraire, voir figure 11
5	Turbo-alternateur de puissance assignée égale ou supérieure à 10 MVA	Voir CEI 60034-3
6	Génératrice à courant continu	Puissance assignée (kW)
7	Moteur à courant continu	Couple assigné (Nm) avec l'excitation d'un moteur shunt maintenant une vitesse assignée, lorsque celle-ci peut-être commandée séparément

6.4 Machines triphasées à courant alternatif fonctionnant sur réseaux isolés

Les machines triphasées à courant alternatif doivent être capables de fonctionner en marche continue avec le neutre à un potentiel proche ou égal à celui de la terre. Elles doivent être aussi capables de fonctionner sur des réseaux isolés ayant une phase au potentiel de la terre pendant des périodes de courtes durées très peu fréquentes, par exemple telles que nécessaires pour affranchir normalement le défaut. S'il est prévu de faire fonctionner la machine en permanence, ou pendant de longues périodes, dans ces conditions, il est indispensable de prévoir une machine spéciale avec le niveau d'isolement approprié.

Si les enroulements n'ont pas une isolation identique côté phase et côté neutre, cela doit être spécifié par le constructeur.

NOTE Il convient que la mise à la terre ou l'interconnexion des points neutres de machines ne soit jamais effectuée sans consultation des constructeurs des machines, à cause des dangers de circulation de courants homopolaires de toutes fréquences dans certaines conditions de fonctionnement et des risques d'incidents mécaniques sur les enroulements lors de défauts entre phase et neutre.

NOTE 1 In practical applications and operating conditions, a machine will sometimes be required to operate outside the perimeter of zone A. Such excursions should be limited in value, duration and frequency of occurrence. Corrective measures should be taken, where practical, within a reasonable time, for example, a reduction in output. Such action may avoid a reduction in machine life from temperature effects.

NOTE 2 The temperature-rise limits or temperature limits in accordance with this standard apply at the rating point and may be progressively exceeded as the operating point moves away from the rating point. For conditions at the extreme boundaries of zone A, the temperature rises and temperatures typically exceed the limits specified in this standard by approximately 10 K.

NOTE 3 An a.c. motor will start at the lower limit of voltage only if its starting torque is adequately matched to the counter-torque of the load, but this is not a requirement of this clause. For starting performance of design N motors, see IEC 60034-12.

Table 2 – Primary functions of machines

Item	Machine type	Primary function
1	AC generator, excluding item 5	Rated apparent power (kVA), at rated power factor where this is separately controllable
2	AC motor, excluding items 3 and 5	Rated torque (Nm)
3	Synchronous motor, excluding item 5	Rated torque (Nm), the excitation maintaining either rated field current or rated power factor, where this is separately controllable
4	Synchronous condenser, excluding item 5	Rated apparent power (kVA) within the zone applicable to a generator, see figure 11, unless otherwise agreed
5	Turbine-type machine, with rated output ≥10 MVA	See IEC 60034-3
6	DC generator	Rated output (kW)
7	DC motor	Rated torque (Nm), the excitation of a shunt motor maintaining rated speed, where this is separately controllable

6.4 Three-phase a.c. machines operating on unearthed systems

Three-phase a.c. machines shall be suitable for continuous operation with the neutral at or near earth potential. They shall also be suitable for operation on unearthed systems with one line at earth potential for infrequent periods of short duration, for example as required for normal fault clearance. If it is intended to run the machine continuously or for prolonged periods in this condition, a machine with a level of insulation suitable for this condition will be required.

If the winding does not have the same insulation at the line and neutral ends, this shall be stated by the manufacturer.

NOTE The earthing or interconnection of the machine's neutral points should not be undertaken without consulting the machine manufacturer because of the danger of zero-sequence components of currents of all frequencies under some operating conditions and the risk of mechanical damage to the windings under line-to-neutral fault conditions.

6.5 Niveaux de tenue en tension (crête et gradient)

Pour les moteurs à courant alternatif, le fabricant doit spécifier une valeur limite pour les crêtes de tension et les gradients de tension, en fonctionnement permanent.

Pour les moteurs à induction à cage couverts par la CEI 60034-12, voir aussi la CEI 60034-17.

Pour les moteurs à courant alternatif à haute tension, voir aussi la CEI 60034-15.

Section 7: Caractéristiques thermiques de fonctionnement et essais thermiques

7.1 Classification thermique

Une classification thermique conforme à la CEI 60085 doit être attribuée aux systèmes d'isolation utilisés dans les machines. La classification des systèmes d'isolation doit s'effectuer au moyen de lettres et non de valeurs de température.

Il est de la responsabilité du constructeur de la machine d'interpréter les résultats obtenus par l'essai d'endurance thermique en fonction du type de la machine et de son application.

NOTE 1 Il est recommandé de ne pas présumer une relation directe entre la classification thermique d'un nouveau système d'isolation et l'aptitude thermique des différents matériaux qui le constituent.

NOTE 2 Il est admis de continuer à utiliser les classifications existantes lorsque celles-ci ont été éprouvées par l'expérience.

7.2 Fluide de refroidissement de référence

Le fluide de refroidissement de référence, pour une méthode donnée de refroidissement, est spécifié dans le tableau 3.

Tableau 3 – Fluide de refroidissement de référence

Point	Fluide de refroidissement primaire	Mode de refroidissement	Fluide de refroidissement secondaire	Tableau n°	Le tableau cité en colonne 4 spécifie des limites à:	Fluide de refroidissement de référence
1	Air	Indirect	Aucun	6	l'échauffement	Air ambiant
2	Air	Indirect	Air	6		
3	Air	Indirect	Eau	6		Fluide de refroidissement à l'entrée dans la machine[1)]
4	Hydrogène	Indirect	Eau	7		
5	Air	Direct	Aucun	11	la température	Air ambiant
6	Air	Direct	Air	11		
7	Air	Direct	Eau	11		Gaz à l'entrée dans la machine ou liquide à l'entrée dans l'enroulement
8	Hydrogène ou liquide	Direct	Eau	11		

[1)] Les caractéristiques assignées d'une machine à refroidissement indirect et à hydroréfrigérant peuvent être attribuées en se servant soit du fluide de refroidissement primaire soit du fluide de refroidissement secondaire comme fluide de refroidissement de référence (voir aussi 9.2 pour l'information à donner sur la plaque signalétique).

6.5 Voltage (peak and gradient) withstand levels

For a.c. motors the manufacturer shall declare a limiting value for the peak voltage and for the voltage gradient in continuous operation.

For cage induction motors within the scope of IEC 60034-12, see also IEC 60034-17.

For high-voltage a.c. motors, see also IEC 60034-15.

Section 7: Thermal performance and tests

7.1 Thermal classification

A thermal classification in accordance with IEC 60085 shall be assigned to the insulation systems used in machines. The classification of the insulation systems shall be by means of letters and not by temperature values.

It is the responsibility of the manufacturer of the machine to interpret the results obtained by thermal endurance testing as appropriate to his machine type and application.

NOTE 1 The thermal classification of a new insulation system should not be assumed to be directly related to the thermal capability of the individual materials used in it.

NOTE 2 The continued use of existing classifications is acceptable where they have been proved by experience.

7.2 Reference coolant

The reference coolant for a given method of cooling the machine is specified in table 3.

Table 3 – Reference coolant

Item	Primary coolant	Method of cooling	Secondary coolant	Table number	Table referred to in column 4 specifies limits of:	Reference coolant
1	Air	Indirect	None	6	Temperature rise	Ambient air
2	Air	Indirect	Air	6		
3	Air	Indirect	Water	6		Coolant at inlet to machine [1)]
4	Hydrogen	Indirect	Water	7		
5	Air	Direct	None	11	Temperature	Ambient air
6	Air	Direct	Air	11		
7	Air	Direct	Water	11		Gas at entry to machine or liquid at entry to the windings
8	Hydrogen or liquid	Direct	Water	11		

[1)] A machine with indirect cooled windings and a water cooled heat exchanger may be rated using either the primary or secondary coolant as the reference coolant (see also 9.2 for information to be given on the rating plate).

Si un troisième fluide de refroidissement est utilisé, les échauffements doivent être mesurés au-dessus de la température du fluide de refroidissement primaire ou secondaire comme spécifié au tableau 3.

NOTE La disposition et le refroidissement d'une machine peuvent être tels que plusieurs points du tableau sont applicables; en ce cas différents fluides de refroidissement de référence peuvent s'appliquer à différents enroulements.

7.3 Conditions des essais thermiques

7.3.1 Alimentation électrique

Pendant l'essai thermique d'un moteur à courant alternatif, le HVF de l'alimentation ne doit pas dépasser 0,015 et la composante inverse du système de tensions doit être inférieure à 0,5 % de la composante directe, l'influence de la composante homopolaire étant éliminée.

Par accord, la composante inverse du système de courants peut être mesurée à la place de la composante inverse du système de tensions. La composante inverse du système de courants ne doit pas excéder 2,5 % de la composante directe.

7.3.2 Température de la machine avant l'essai

Lorsque la température d'un enroulement doit être déterminée d'après l'augmentation de la résistance, la température de l'enroulement, mesurée par thermomètre, lorsque la résistance est mesurée avant l'essai thermique, doit être pratiquement celle du fluide de refroidissement à ce moment.

Lorsqu'une machine doit être essayée à des caractéristiques assignées pour service temporaire (service type S2), sa température au début de l'essai ne doit pas différer de plus de 5 K de la température du fluide de refroidissement.

7.3.3 Température du fluide de refroidissement

L'essai de la machine peut être effectué à toute température disponible du fluide de refroidissement. Voir tableau 10 (pour les enroulements à refroidissement direct) ou tableau 13 (pour les enroulements à refroidissement indirect).

7.3.4 Mesurage de la température du fluide de refroidissement au cours des essais

La valeur à adopter pour la température du fluide de refroidissement pendant un essai doit être la moyenne des lectures effectuées sur les détecteurs de température à intervalles de temps égaux pendant le dernier quart de la durée de l'essai. Pour réduire les erreurs qui peuvent provenir de la lenteur avec laquelle la température des grandes machines suit les variations de la température du fluide de refroidissement, toutes dispositions raisonnables doivent être prises pour réduire ces variations.

7.3.4.1 Machines ouvertes ou machines fermées sans échangeurs de chaleur (refroidies par de l'air ou du gaz environnant)

La température ambiante de l'air ou du gaz doit être mesurée au moyen de plusieurs détecteurs de température répartis autour et à mi-hauteur de la machine, à une distance de 1 m à 2 m de celle-ci. Chaque détecteur doit être à l'abri de toute chaleur rayonnée et des courants d'air.

If a third coolant is used, temperature rise shall be measured above the temperature of the primary or secondary coolant as specified in table 3.

NOTE A machine may be so arranged and cooled that more than one item of table 3 applies, in which case different reference coolants may apply for different windings.

7.3 Conditions for thermal tests

7.3.1 Electrical supply

During thermal testing of an a.c. motor the HVF of the supply shall not exceed 0,015 and the negative-sequence component of the system of voltages shall be less than 0,5 % of the positive-sequence component, the influence of the zero-sequence component being eliminated.

By agreement, the negative-sequence component of the system of currents may be measured instead of the negative-sequence component of the system of voltages. The negative-sequence component of the system of currents shall not exceed 2,5 % of the positive-sequence component.

7.3.2 Temperature of machine before test

If the temperature of a winding is to be determined from the increase of resistance, the temperature of the winding measured by thermometer, when the resistance is measured before the thermal test, shall be practically that of the coolant at the time.

When a machine is to be tested on a short-time rating (duty type S2) its temperature at the beginning of the thermal test shall be within 5 K of the temperature of the coolant.

7.3.3 Temperature of coolant

A machine may be tested at any convenient value of coolant temperature. See table 10 (for indirect cooled windings) or table 13 (for direct cooled windings).

7.3.4 Measurement of coolant temperature during test

The value to be adopted for the temperature of a coolant during a test shall be the mean of the readings of the temperature detectors taken at equal intervals of time during the last quarter of the duration of the test. To reduce errors due to the time lag of the change of temperature of large machines following variations in the temperature of the coolant, all reasonable precautions shall be taken to minimize such variations.

7.3.4.1 Open machines or closed machines without heat exchangers (cooled by surrounding ambient air or gas)

The temperature of the ambient air or gas shall be measured by means of several detectors placed at different points around and halfway up the machine at 1 m to 2 m from it. Each detector shall be protected from radiant heat and draughts.

7.3.4.2 Machines refroidies par de l'air ou du gaz à partir d'une source éloignée à travers des conduits de ventilation et machines à échangeurs de chaleur montés séparément

La température du fluide de refroidissement primaire doit être mesurée à l'entrée dans la machine.

7.3.4.3 Machines fermées à échangeurs de chaleur montés sur la machine ou incorporés

La température du fluide de refroidissement primaire doit être mesurée à l'entrée dans la machine. La température du fluide de refroidissement secondaire doit être mesurée à l'entrée dans l'échangeur de chaleur.

7.4 Echauffement d'un élément de machine

L'échauffement d'un élément de machine, $\Delta\theta$, est la différence entre la température de cet élément, mesurée par la méthode appropriée, conformément à 7.5, et la température du fluide de refroidissement, mesurée conformément à 7.3.4.

Pour la comparaison avec les limites des échauffements (voir tableau 6 ou 7) ou des températures (voir tableau 11), lorsque cela est possible la température doit être mesurée immédiatement avant qu'on arrête la machine à la fin de l'essai thermique, comme cela est défini à l'article 7.7.

Lorsque cela n'est pas possible, par exemple lors du mesurage direct par la méthode de variation de résistance, voir 7.6.2.3.

Pour les machines essayées à leur service périodique réel (services types S3 à S8) la température doit être prise comme étant celle au milieu de la période donnant le plus grand échauffement dans le dernier cycle de fonctionnement (mais voir aussi 7.7.3).

7.5 Méthodes de mesurage de la température

Trois méthodes sont admises pour déterminer les températures des enroulements et des autres éléments:

– méthode par variation de résistance;

– méthode par indicateurs internes de température (IIT);

– méthode par thermomètre.

Les différentes méthodes ne doivent pas être utilisées pour un contrôle mutuel.

7.5.1 Méthode par variation de résistance

La température des enroulements est déterminée à partir de l'augmentation de leur résistance.

7.5.2 Méthode par indicateurs internes de température (IIT)

La température est mesurée au moyen d'indicateurs internes de température (par exemple; thermomètres à résistances, couples thermoélectriques ou thermistances à semi-conducteurs à coefficient de température négatif) introduits dans la machine lors de la construction, en des points qui deviennent inaccessibles lorsque la machine est terminée.

7.3.4.2 Machines cooled by air or gas from a remote source through ventilation ducts and machines with separately mounted heat exchangers

The temperature of the primary coolant shall be measured where it enters the machine.

7.3.4.3 Closed machines with machine-mounted or internal heat exchangers

The temperature of the primary coolant shall be measured where it enters the machine. The temperature of the secondary coolant shall be measured where it enters the heat exchanger.

7.4 Temperature rise of a part of a machine

The temperature rise, $\Delta\theta$, of a part of a machine is the difference between the temperature of that part measured by the appropriate method in accordance with 7.5, and the temperature of the coolant measured in accordance with 7.3.4.

For comparison with the limits of temperature rise (see table 6 or 7) or of temperature (see table 11), when possible, the temperature shall be measured immediately before the machine is shut down at the end of the thermal test, as described in clause 7.7.

When this is not possible, e.g. when using the direct measurement of resistance method, see 7.6.2.3.

For machines tested on actual periodic duty (duty types S3 to S8) the temperature at the end of the test shall be taken as that at the middle of the period causing the greatest heating in the last cycle of operation (but see also 7.7.3).

7.5 Methods of measurement of temperature

Three methods of measuring the temperature of windings and other parts are recognized:

– resistance method;

– embedded temperature detector (ETD) method;

– thermometer method.

Different methods shall not be used as a check upon one another.

7.5.1 Resistance method

The temperature of the windings is determined from the increase of the resistance of the windings.

7.5.2 Embedded temperature detector (ETD) method

The temperature is determined by means of temperature detectors (e.g. resistance thermometers, thermocouples or semi-conductor negative coefficient detectors) built into the machine during construction, at points which are inaccessible after the machine is completed.

7.5.3 Méthode par thermomètre

La température est mesurée au moyen de thermomètres appliqués sur les surfaces accessibles de la machine terminée. Le terme «thermomètre» s'applique non seulement aux thermomètres à réservoir, mais aussi aux couples thermoélectriques et thermomètres à résistance externes. Lorsque des thermomètres à réservoir sont utilisés en des points où il existe un champ magnétique intense, variable ou mobile, des thermomètres à alcool doivent être utilisés de préférence aux thermomètres à mercure.

7.6 Détermination de la température d'enroulement

7.6.1 Choix de la méthode

En général, pour mesurer la température des enroulements d'une machine, la méthode par variation de résistance, conforme à 7.5.1, doit être appliquée (mais voir aussi 7.6.2.3.3).

Pour les enroulements statoriques à courant alternatif des machines de puissance assignée égale ou supérieure à 5 000 kW (ou kVA), la méthode par indicateurs internes de température (IIT) doit être appliquée.

Pour les machines à courant alternatif de puissance assignée inférieure à 5 000 kW (ou kVA) et supérieure à 200 kW (ou kVA), le constructeur doit choisir soit la méthode par variation de résistance, soit la méthode par indicateurs internes de température, sauf accord contraire.

Pour les machines à courant alternatif de puissance assignée inférieure ou égale à 200 kW (ou kVA), le constructeur doit choisir la méthode par variation de résistance, par mesurage direct ou par méthode par superposition, sauf accord contraire (mais voir aussi ci-dessous).

Pour les machines de puissance assignée inférieure ou égale à 600 W (ou VA), si les enroulements ne sont pas uniformes ou si la réalisation des connexions nécessaires entraîne de sévères complications, la température peut être déterminée au moyen de thermomètres. Les limites d'échauffement, conformes au tableau 6, doivent être appliquées.

La méthode par thermomètre est admise dans les cas suivants:

a) Lorsque la détermination de l'échauffement par variation de résistance n'est pas réalisable en pratique, comme par exemple dans le cas des bobines de commutation et enroulements compensateurs de faible résistance et, de façon générale, dans le cas des enroulements de faible résistance, notamment lorsque la résistance des jonctions et connexions représente une proportion importante de la résistance totale.

b) Enroulements en une seule couche, tournants ou fixes.

c) Lors des essais individuels sur machines fabriquées en grande série.

Pour les enroulements statoriques à courant alternatif à un seul faisceau par encoche, la méthode par indicateurs internes de température ne doit pas être utilisée pour vérifier la conformité à la présente norme: la méthode par variation de résistance doit être appliquée.

NOTE Pour vérifier en service la température de tels enroulements, un indicateur interne placé au fond de l'encoche est de peu de valeur du fait qu'il indique principalement la température du fer. Un indicateur placé entre la bobine et la cale d'encoche suit beaucoup plus fidèlement la température de l'enroulement et est donc préférable à des fins de surveillance en fonctionnement. Puisque la température de cet endroit peut être relativement basse, il convient de déterminer par un essai d'échauffement la relation entre la température mesurée à cet endroit et la température mesurée par variation de résistance.

Pour les autres enroulements à un seul faisceau par encoche et pour les développantes, la méthode de mesure de température par IIT ne doit pas être utilisée pour vérifier la conformité à la présente norme.

7.5.3 Thermometer method

The temperature is determined by thermometers applied to accessible surfaces of the completed machine. The term 'thermometer' includes not only bulb-thermometers, but also non-embedded thermocouples and resistance thermometers. When bulb-thermometers are used in places where there is a strong varying or moving magnetic field, alcohol thermometers shall be used in preference to mercury thermometers.

7.6 Determination of winding temperature

7.6.1 Choice of method

In general, for measuring the temperature of the windings of a machine, the resistance method in accordance with 7.5.1 shall be applied (but see also 7.6.2.3.3).

For a.c. stator windings of machines having a rated output of 5 000 kW (or kVA) or more the ETD method shall be used.

For a.c. machines having a rated output less than 5 000 kW (or kVA) but greater than 200 kW (or kVA) the manufacturer shall choose either the resistance or the ETD method, unless otherwise agreed.

For a.c. machines having a rated output less than or equal to 200 kW (or kVA) the manufacturer shall choose the direct measurement version or the superposition version of the resistance method, unless otherwise agreed (but see also below).

For machines having a rated output less than or equal to 600 W (or VA), when the windings are non-uniform or severe complications are involved in making the necessary connections, the temperature may be determined by means of thermometers. Temperature rise limits in accordance with table 6 shall apply.

The thermometer method is recognized in the following cases:

a) When it is not practicable to determine the temperature rise by the resistance method as, for example, with low-resistance commutating coils and compensating windings and, in general, in the case of low-resistance windings, especially when the resistance of joints and connections forms a considerable proportion of the total resistance.
b) Single layer windings, rotating or stationary.
c) During routine tests on machines manufactured in large numbers.

For a.c. stator windings having only one coil-side per slot, the ETD method shall not be used for verifying compliance with this standard: the resistance method shall be used.

NOTE For checking the temperature of such windings in service, an embedded detector at the bottom of the slot is of little value because it gives mainly the temperature of the iron core. A detector placed between the coil and the wedge will follow the temperature of the winding much more closely and is, therefore, better for checks in service. Because the temperature there may be rather low the relation between it and the temperature measured by the resistance method should be determined by a thermal test.

For other windings having one coil-side per slot and for end windings the ETD method shall not be used for verifying compliance with this standard.

Pour les enroulements d'induits à collecteurs et pour les enroulements d'excitation, à l'exception des enroulements d'excitation dans les rotors cylindriques des machines synchrones, la méthode par variation de résistance et la méthode par thermomètre sont admises. La méthode préférée est la méthode par variation de résistance, mais pour les enroulements d'excitation fixes des machines à courant continu à plus d'une couche, la méthode par indicateurs internes de température peut être utilisée.

7.6.2 Détermination par la méthode par variation de résistance

7.6.2.1 Mesurage

L'une des méthodes suivantes doit être utilisée.

7.6.2.1.1 Mesurage direct

Mesurage direct, au début et à la fin de l'essai, en utilisant un instrument ayant une gamme appropriée.

7.6.2.1.2 Mesurage en courant continu de courant et tension

Pour enroulements à courant continu: en mesurant le courant dans l'enroulement et la tension à ses bornes, utilisant des instruments aux gammes appropriées.

Pour enroulements à courant alternatif: en injectant du courant continu dans l'enroulement, en l'absence de tension alternative.

7.6.2.1.3 Méthode par superposition

Sans interruption du courant alternatif de charge, en superposant au courant de charge un courant continu de mesure de faible intensité, selon la CEI 60279.

7.6.2.2 Calcul

L'échauffement $\theta_2 - \theta_a$, peut être obtenu à partir de l'équation

$$\frac{\theta_2 + k}{\theta_1 + k} = \frac{R_2}{R_1}$$

où

θ_1 est la température (°C) de l'enroulement (froid) au moment de la mesure de la résistance initiale;

θ_2 est la température (°C) de l'enroulement à la fin de l'essai;

θ_a est la température (°C) du fluide de refroidissement à la fin de l'essai thermique;

R_1 est la résistance de l'enroulement à la température θ_1 (froid);

R_2 est la résistance de l'enroulement à la fin de l'essai thermique;

k est l'inverse du coefficient de variation de résistivité en fonction de la température à 0 °C du matériau conducteur.

Pour le cuivre k = 235

Pour l'aluminium k = 225 sauf spécification contraire.

Dans la pratique, il est commode de calculer l'échauffement par la formule équivalente suivante:

$$\theta_2 - \theta_a = \frac{R_2 - R_1}{R_1} \times (k + \theta_1) + \theta_1 - \theta_a$$

For windings of armatures having commutators and for field windings, except for field windings in cylindrical rotors of synchronous machines, the resistance method and the thermometer method are recognized. The resistance method is preferred but for stationary field windings of d.c. machines having more than one layer the ETD method may be used.

7.6.2 Determination by resistance method

7.6.2.1 Measurement

One of the following methods shall be used.

7.6.2.1.1 Direct measurement

Direct measurement at the beginning and the end of the test, using an instrument having a suitable range.

7.6.2.1.2 Measurement by d.c. current/voltage

For d.c. windings: by measuring the current in and the voltage across the winding, using instruments having suitable ranges.

For a.c. windings: by injecting direct current into the winding when de-energized.

7.6.2.1.3 Superposition method

Without interruption of the a.c. load current by superimposing on the load current a small d.c. measuring current, in accordance with IEC 60279.

7.6.2.2 Calculation

The temperature rise, $\theta_2 - \theta_a$, may be obtained from the equation:

$$\frac{\theta_2 + k}{\theta_1 + k} = \frac{R_2}{R_1}$$

where

θ_1 is the temperature (°C) of the winding (cold) at the moment of the initial resistance measurement;

θ_2 is the temperature (°C) of the winding at the end of the thermal test;

θ_a is the temperature of the coolant at the end of the thermal test;

R_1 is the resistance of the winding at temperature θ_1 (cold);

R_2 is the resistance of the winding at the end of the thermal test;

k is the reciprocal of the temperature coefficient of resistance at 0 °C of the conductor material.

For copper k = 235

For aluminium k = 225 unless specified otherwise.

For practical purposes, the following alternative formula may be found convenient:

$$\theta_2 - \theta_a = \frac{R_2 - R_1}{R_1} \times (k + \theta_1) + \theta_1 - \theta_a$$

7.6.2.3 Correction pour des mesures relevées après arrêt de la machine

Le mesurage des températures, à la fin de l'essai thermique, par la méthode de variation de résistance exige que la machine arrive rapidement à l'arrêt. Une procédure soigneusement planifiée et un nombre approprié de personnes sont nécessaires.

7.6.2.3.1 Arrêt de la machine en un temps court

Si la lecture initiale par variation de résistance est obtenue dans le délai indiqué au tableau 4, cette lecture doit être adoptée pour la mesure de la température.

Tableau 4 – Délai

Puissance assignée (P_N) kW ou kVA	**Délai après la coupure** s
$P_N \leq 50$	30
$50 < P_N \leq 200$	90
$200 < P_N \leq 5\,000$	120
$5000 < P_N$	Sur accord

7.6.2.3.2 Arrêt de la machine en un temps prolongé

Si la lecture par variation de résistance ne peut être effectuée dans le délai spécifié au tableau 4, elle doit être faite le plus tôt possible mais dans un délai non supérieur à deux fois celui spécifié au tableau 4, et des lectures supplémentaires doivent être effectuées à des intervalles d'environ 1 min, jusqu'au moment où ces lectures commencent à montrer une diminution sensible de leurs valeurs maximales. Une courbe de ces lectures doit être tracée en fonction du temps et extrapolée au délai spécifié dans le tableau ci-dessus pour la puissance assignée de la machine. Il est recommandé de tracer une courbe semi-logarithmique, où la température figure sur l'ordonnée logarithmique. La valeur de la température ainsi obtenue doit être considérée comme la température au moment de l'arrêt de la machine. Si des mesures consécutives montrent une augmentation des températures après l'arrêt, la valeur la plus élevée doit être prise.

Si la lecture initiale par variation de résistance ne peut être effectuée qu'après un délai égal à deux fois le délai spécifié au tableau 4, cette méthode de correction ne doit être utilisée que par accord.

7.6.2.3.3 Enroulements à un faisceau par encoche

Pour les machines à un faisceau par encoche, la méthode par variation de résistance par mesurage direct peut être appliquée si la machine parvient à l'arrêt dans le délai spécifié dans le tableau 4. S'il faut à la machine plus de 90 s pour arriver à l'arrêt après la coupure, la méthode par superposition peut être appliquée s'il y a eu un accord préalable.

7.6.3 Détermination par la méthode par indicateurs internes de température (IIT)

Les indicateurs doivent être convenablement répartis dans l'enroulement de la machine, et le nombre des indicateurs installés ne doit pas être inférieur à six.

On doit s'efforcer, dans toute la mesure compatible avec la sécurité, de placer les indicateurs aux différents points présumés les plus chauds de façon qu'ils soient efficacement protégés d'un contact avec le fluide de refroidissement primaire.

7.6.2.3 Correction for stopping time

The measurement of temperatures at the end of the thermal test by the direct measurement resistance method requires a quick shutdown. A carefully planned procedure and an adequate number of people are required.

7.6.2.3.1 Short stopping time

If the initial resistance reading is obtained within the time interval specified in table 4, that reading shall be accepted for the temperature measurement.

Table 4 – Time interval

Rated output (P_N) kW or kVA	**Time interval after switching off power** s
$P_N \leq 50$	30
$50 < P_N \leq 200$	90
$200 < P_N \leq 5\,000$	120
$5000 < P_N$	By agreement

7.6.2.3.2 Extended stopping time

If a resistance reading cannot be made in the time interval specified in table 4, it shall be made as soon as possible but after not more than twice the interval specified in table 4, and additional readings shall be taken at intervals of approximately 1 min until these readings have begun a distinct decline from their maximum value. A curve of these readings shall be plotted as a function of time and extrapolated to the time interval for the rated output of the machine. A semi-logarithmic plot is recommended where temperature is plotted on the logarithmic scale. The value of temperature thus obtained shall be considered as the temperature at shutdown. If successive measurements show increasing temperatures after shutdown the highest value shall be taken.

If a resistance reading cannot be made until after twice the time interval specified in table 4, this method of correction shall only be used by agreement.

7.6.2.3.3 Windings with one coil-side per slot

For machines with one coil-side per slot the resistance method by direct measurement may be used if the machine comes to rest within the time interval specified in table 4. If the machine takes more that 90 s to come to rest after switching off the power, the superposition method may be used if previously agreed.

7.6.3 Determination by ETD method

The detectors shall be suitable distributed throughout the winding and the number of detectors installed shall not be less than six.

All reasonable efforts, consistent with safety, shall be made to place the detectors at the points where the highest temperatures are likely to occur, in such a manner that they are effectively protected against contact with the primary coolant.

La lecture la plus élevée des éléments IIT doit être utilisée pour déterminer la température de l'enroulement.

NOTE Les éléments IIT ou leurs connexions peuvent présenter un défaut et donner des lectures incorrectes. En conséquence, si une ou plusieurs lectures s'avèrent, après analyse, être erratiques, il convient de les éliminer.

7.6.3.1 Deux faisceaux par encoche ou plus

Les indicateurs de température doivent être placés entre les faisceaux isolés à l'intérieur de l'encoche, aux endroits présumés les plus chauds.

7.6.3.2 Un faisceau par encoche

Les indicateurs doivent être placés entre la cale d'encoche et la partie externe de l'isolation d'enroulement, aux endroits présumés les plus chauds; voir 7.6.1.

7.6.3.3 Développantes

Les indicateurs de température doivent être placés entre deux faisceaux adjacents de développantes, aux endroits présumés les plus chauds. La partie sensible de chaque indicateur doit être en contact étroit avec la surface du faisceau et être efficacement protégée de l'influence du fluide de refroidissement; voir 7.6.1.

7.6.4 Détermination par la méthode du thermomètre

Lorsqu'on utilise un couple thermoélectrique ou thermomètre à résistance externe, il ne doit pas être placé à un point inaccessible à un thermomètre à réservoir.

On doit s'efforcer, autant que cela est compatible avec la sécurité, de placer les thermomètres aux points présumés les plus chauds (par exemple dans les développantes à proximité du circuit magnétique) de façon qu'ils soient efficacement protégés du contact avec le fluide de refroidissement primaire et qu'ils soient en bon contact thermique avec l'enroulement ou autre élément de machine.

Quel que soit le thermomètre, la lecture la plus élevée doit être prise comme valeur de la température de l'enroulement ou de l'élément de machine.

7.7 Durée des essais thermiques

7.7.1 Caractéristiques assignées pour service continu

L'essai doit durer jusqu'à ce que l'équilibre thermique soit atteint.

7.7.2 Caractéristiques assignées pour service temporaire

La durée de l'essai doit être la durée qui est indiquée dans les caractéristiques assignées.

7.7.3 Caractéristiques assignées pour service périodique

Normalement les caractéristiques assignées pour charge équivalente (voir 4.2.6) attribuées par le constructeur doivent être appliquées jusqu'à ce que l'équilibre thermique soit atteint. S'il y a accord pour effectuer un essai au service réel, le cycle de charge spécifié doit être appliqué jusqu'à l'obtention de cycles de température pratiquement identiques. Le critère en est que la droite reliant les points correspondants de deux cycles de charge successifs sur un diagramme de température doit avoir une pente inférieure à 2 K par heure. Si nécessaire, il faut effectuer des mesures à intervalles raisonnables pendant un certain laps de temps.

The highest reading from the ETD elements shall be used to determine the temperature of the winding.

NOTE ETD elements or their connections may fail and give incorrect readings. Therefore, if one or more readings are shown to be erratic, after investigation they should be eliminated.

7.6.3.1 Two or more coil-sides per slot

The detectors shall be located between the insulated coil-sides within the slot in positions at which the highest temperatures are likely to occur.

7.6.3.2 One coil-side per slot

The detectors shall be located between the wedge and the outside of the winding insulation in positions at which the highest temperatures are likely to occur, but see also 7.6.1.

7.6.3.3 End windings

The temperature detectors shall be located between two adjacent coil-sides within the end windings in positions where the highest temperatures are likely to occur. The sensing point of each detector shall be in close contact with the surface of a coil-side and be adequately protected against the influence of the coolant, but see also 7.6.1.

7.6.4 Determination by thermometer method

When a non-embedded thermocouple or a resistance thermometer is used, it shall not be placed at a point inaccessible to a bulb thermometer.

All reasonable efforts, consistent with safety, shall be made to place thermometers at the point, or points where the highest temperatures are likely to occur (e.g. in the end windings close to the core iron) in such a manner that they are effectively protected against contact with the primary coolant and are in good thermal contact with the winding or other part of the machine.

The highest reading from any thermometer shall be taken to be the temperature of the winding or other part of the machine.

7.7 Duration of thermal tests

7.7.1 Rating for continuous running duty

The test shall be continued until thermal equilibrium has been reached.

7.7.2 Rating for short-time duty

The duration of the test shall be the time given in the rating.

7.7.3 Rating for periodic duty

Normally the rating for equivalent loading assigned by the manufacturer (see 4.2.6) shall be applied until thermal equilibrium has been reached. If a test on the actual duty is agreed the load cycle specified shall be applied and continued until practically identical temperature cycles are obtained. The criterion for this shall be that a straight line between the corresponding points of successive duty cycles on a temperature plot has a gradient of less that 2 K per hour. If necessary, measurements shall be taken at reasonable intervals over a period of time.

7.7.4 Caractéristiques assignées pour service non périodique et caractéristiques assignées pour service avec charges constantes distinctes

Les caractéristiques assignées pour charge équivalente (voir 4.2.6), attribuées par le constructeur doivent être appliquées jusqu'à ce que l'équilibre thermique soit atteint.

7.8 Détermination de la constante de temps thermique équivalente des machines pour service type S9

La constante de temps thermique équivalente (avec une ventilation telle qu'en condition normale de fonctionnement) appropriée pour la détermination approchée de l'évolution de la température peut être déterminée à partir de la courbe de refroidissement tracée conformément à 7.6.2.3. La valeur de la constante de temps est égale à 1,44 fois (c'est-à-dire 1/ln2 fois) le délai entre la déconnexion du moteur et le refroidissement à une température correspondant à la moitié de l'échauffement de la machine à pleine charge.

7.9 Mesurage de la température des paliers

L'une ou l'autre des méthodes par thermomètre ou par indicateur interne de température (IIT) est admise.

Le point de mesure doit être placé aussi près que possible de l'un des deux emplacements spécifiés au tableau 5.

Tableau 5 – Points de mesure

Type de palier	Point de mesure	Emplacement du point de mesure
A roulement à billes ou à rouleaux	A	Dans le logement du roulement et à une distance [1] de la bague extérieure du roulement ne dépassant pas 10 mm [2]
	B	Surface extérieure du logement du roulement le plus près possible de la bague extérieure du roulement
A coussinet	A	Dans la zone de pression de la coquille du coussinet [3] et à une distance[1] du film d'huile ne dépassant pas 10 mm [2]
	B	A un autre endroit de la coquille du coussinet

[1] La distance est mesurée à partir du point le plus proche de l'indicateur interne ou du thermomètre.

[2] Dans le cas d'une machine à rotor extérieur, le point A se trouve dans la partie fixe à une distance de la bague intérieure ne dépassant pas 10 mm et le point B se trouve sur la surface extérieure de la partie fixe, aussi près que possible de la bague intérieure.

[3] La coquille du coussinet est la partie supportant le matériau du coussinet qui est pressé et fixé dans le logement. La zone de pression est la portion de circonférence qui supporte la combinaison du poids du rotor et des charges radiales.

Il faut minimiser la résistance thermique entre l'indicateur interne de température et l'objet dont on mesure la température, par exemple, chaque interstice d'air doit être comblé par un produit conducteur de la chaleur.

NOTE Entre les points de mesure A et B comme entre ces points et le point le plus chaud du palier, il existe des différences de température qui dépendent, entre autres, de la dimension du palier. Pour les paliers à coussinets cylindriques emmanchés en force et pour les paliers à roulements à bille ou à rouleaux d'un diamètre intérieur inférieur ou égal à 150 mm, les différences de température qui se produisent entre les points de mesure A et B peuvent être présumées négligeables. Dans le cas des paliers plus grands, la différence de température entre les points de mesure A et B est approximativement 15 K.

7.7.4 Ratings for non-periodic duty and for duty with discrete constant loads

The rating for equivalent loading assigned by the manufacturer (see 4.2.6) shall be applied until thermal equilibrium has been reached.

7.8 Determination of the thermal equivalent time constant for machines of duty type S9

The thermal equivalent time constant with ventilation as in normal operating conditions, suitable for approximate determination of the temperature course, can be determined from the cooling curve plotted in the same manner as in 7.6.2.3. The value of the time constant is 1,44 times (i.e. 1/ln2 times) the time taken by the machine to cool to one-half of the full load temperature rise, after its disconnection from the supply.

7.9 Measurement of bearing temperature

Either the thermometer method or the ETD method may be used.

The measuring point shall be as near as possible to one of the two locations specified in table 5.

Table 5 – Measuring points

Type of bearing	Measuring point	Location of measuring point
Ball or roller	A	In the bearing housing and not more than 10 mm[1)] from the outer ring of the bearing [2)]
	B	Outer surface of the bearing housing as close as possible to the outer ring of the bearing
Sleeve	A	In the pressure zone of the bearing shell[3)] and not more than 10 mm[1)] from the oil-film gap [2)].
	B	Elsewhere in the bearing shell

[1)] The distance is measured to the nearest point of the ETD or thermometer bulb.

[2)] In the case of an 'inside out' machine, point A will be in the stationary part not more than 10 mm from the inner ring and point B on the outer surface of the stationary part as close as possible to the inner ring.

[3)] The bearing shell is the part supporting the bearing material and which is secured in the housing. The pressure zone is the portion of the circumference which supports the combination of rotor weight and radial loads.

The thermal resistance between the temperature detector and the object whose temperature is to be measured shall be minimized; for example, air gaps shall be packed with thermally conducting paste.

NOTE Between the measuring points A and B, as well as between these points and the hottest point of the bearing, there are temperature differences which depend, among other things, on the bearing size. For sleeve bearings with pressed-in bushings and for ball and roller bearings with an inside diameter up to 150 mm, the temperature difference between points A and B may be assumed to be negligible. In the case of larger bearings, the temperature difference between measuring points A and B is approximately 15 K.

7.10 Limites d'échauffement et de température

Des limites sont données pour marche aux conditions de fonctionnement sur site, définies à l'article 5, et aux caractéristiques assignées pour service continu (conditions de référence), suivies par des règles donnant les corrections à ces limites en cas de marche sur site avec d'autres conditions de fonctionnement et avec d'autres caractéristiques assignées. Des règles additionnelles donnent les corrections aux limites pendant l'essai thermique en cas de conditions de fonctionnement au site d'essai différentes de celles au site de fonctionnement.

Les limites sont stipulées par rapport au fluide de refroidissement de référence défini au tableau 3.

Une règle est donnée pour tenir compte de la pureté d'hydrogène.

7.10.1 Enroulements à refroidissement indirect

Les échauffements aux conditions de référence ne doivent pas excéder les limites données au tableau 6 (refroidissement par air) ou au tableau 7 (refroidissement par hydrogène) selon le cas.

Pour des conditions différentes de fonctionnement sur site, pour des caractéristiques assignées autres que celles pour service continu et pour des tensions assignées supérieures à 11 000 V, les limites doivent être corrigées selon le tableau 8. (Voir aussi le tableau 9 pour une limite à la température de fluide de refroidissement qui est présumée dans le tableau 8.)

En cas de lectures par thermomètre effectuées selon 7.6.1, la limite d'échauffement doit être conforme au tableau 6.

Si pour les enroulements à refroidissement indirect par air, les conditions de fonctionnement sur site d'essai diffèrent de celles sur site de fonctionnement, les limites corrigées données au tableau 10 doivent s'appliquer au site d'essai.

Si les limites corrigées données au tableau 10 conduisent à des températures admissibles au site d'essai que le constructeur juge excessives, la méthode d'essai et les limites doivent faire l'objet d'un accord.

Aucune correction pour le site d'essai n'est donnée pour les enroulements à refroidissement indirect par hydrogène car il est très improbable qu'ils soient essayés à pleine charge, ailleurs qu'à leur site de fonctionnement.

7.10 Limits of temperature and of temperature rise

Limits are given for operation under site operating conditions specified in clause 5 and at rating for continuous running duty (reference conditions), followed by rules for the adjustment of those limits when operating at site under other conditions and on other ratings. Further rules give adjustments to the limits during thermal testing when conditions at the test site differ from those at the operating site.

The limits are stated relative to the reference coolant specified in table 3.

A rule is given to allow for the purity of hydrogen coolant.

7.10.1 Indirect cooled windings

Temperature rises under reference conditions shall not exceed the limits given in table 6 (air coolant) or table 7 (hydrogen coolant) as appropriate.

For other operating site conditions, for ratings other than continuous running duty, and for rated voltages greater than 11 000 V, the limits shall be adjusted according to table 8. (See also table 9 for limit on coolant temperature which is assumed in table 8.)

In the case of thermometer readings made in accordance with 7.6.1, the limit of temperature rise shall be according to table 6.

If, for windings indirectly cooled by air, conditions at the test site differ from those at the operating site, the adjusted limits given in table 10 shall apply at the test site.

If the adjusted limits given in table 10 lead to permissible temperatures at the test site which the manufacturer considers to be excessive, the testing procedure and the limits shall be agreed.

No adjustments at the test site are given for windings indirectly cooled by hydrogen, because it is very unlikely that they will be tested at rated load anywhere other than at the operating site.

1d)	AC windings of machines having rated outputs of less than 600 W (or VA)[2)]	–	65	–	–	75	–	–	85	–	–	110	–	–	130	–
1e)	AC windings which are self-cooled without a fan (IC 40) and/or with encapsulated windings[2)]	–	65	–	–	75	–	–	85	–	–	110	–	–	130	–
2	Windings of armatures having commutators	50	60	–	65	75	–	70	80	–	85	105	–	105	125	–
3	Field windings of a.c. and d.c. machines other than those in item 4	50	60	–	65	75	–	70	80	–	85	105	–	105	125	–
4a)	Field windings of synchronous machines with cylindrical rotors having a d.c. excitation winding embedded in slots, except synchronous induction motors	–	–	–	–	–	–	–	90	–	–	110	–	–	135	–
4b)	Insulated stationary field windings of d.c. machines having more than one layer	50	60	–	65	75	–	70	80	90	85	105	110	105	125	135
4c)	Low-resistance field windings of a.c. and d.c. machines having more than one layer and compensating windings of d.c. machines	60	60	–	75	75	–	80	80	–	100	100	–	125	125	–
4d)	Single-layer windings of a.c. and d.c. machines with exposed bare or varnished metal surfaces.[3)]	65	65	–	80	80	–	90	90	–	110	110	–	135	135	–

[1)] An adjustment for high-voltage a.c. windings may be applicable to these items, (see item 4 of table 8).

[2)] With the application of the superposition test method to windings of machines rated at 200 kW (or kVA) or less with thermal classes A, B, E and F, the limits of temperature rise given for the resistance method may be exceeded by 5 K.

[3)] Also includes multiple layer windings provided that the under layers are each in contact with the circulating primary coolant.

Tableau 7 – Limites d'échauffement des enroulements à refroidissement indirect par hydrogène

Classification thermique		A		E		B		F	
Méthode de mesure IIT = Indicateur interne de température		Résistance K	IIT K	Résistance K	IIT K	Résistance K	IIT K	Résistance K	IIT K
Point									
1	Enroulements à courant alternatif de machines de puissance égale ou supérieure à 5 000 kW (ou kVA) ou dont la longueur du noyau axial est égale ou supérieure à 1 m								
	Pression absolue d'hydrogène[2] ≤ 150 kPa (1,5 bar)	–	–	–	–	–	85[1]	–	105[1]
	> 150 kPa ≤ 200 kPa (2,0 bar)	–	–	–	–	–	80[1]	–	100[1]
	> 200 kPa ≤ 300 kPa (3,0 bar)	–	–	–	–	–	78[1]	–	98[1]
	> 300 kPa ≤ 400 kPa (4,0 bar)	–	–	–	–	–	73[1]	–	93[1]
	> 400 kPa	–	–	–	–	–	70[1]	–	90[1]
2a)	Enroulements à courant alternatif de machine de puissance inférieure à 5 000 kW (ou KVA) et dont la longueur du noyau axial est inférieure à 1 m	60	65[1]	75	80[1]	80	85[1]	100	105[1]
2b)	Enroulements d'excitation à courant continu des machines à courant alternatif et à courant continu autres que celles des points 3 et 4	80	–	75	–	80	–	105	–
3	Enroulements d'excitation à courant continu des turbo-machines	–	–	–	–	85	–	105	–
4a)	Enroulements d'excitation de faible résistance, à plus d'une couche, et enroulements de compensation	60	–	75	–	80	–	100	–
4b)	Enroulements à une couche avec surfaces exposées nues ou en métal vernis [3]	65	–	80	–	90	–	110	–

[1] Une correction peut être effectuée dans le cas des enroulements à courant alternatif à haute tension (voir point 4 du tableau 8).

[2] Ce point est le seul pour lequel l'échauffement admissible dépend de la pression d'hydrogène.

[3] Comprend également les enroulements d'excitation à plusieurs couches, à condition que les couches inférieures soient chacune en contact avec le fluide de refroidissement primaire en circulation.

Table 7 – Limits of temperature rise of windings indirectly cooled by hydrogen

Item									
1	AC windings of machines having outputs of 5 000 kW (or kVA) or more or having a core length of 1 m or more								
	Absolute hydrogen pressure [2] ≤ 150 kPa (1,5 bar)	–	–	–	–	–	85[1]	–	105[1]
	> 150 kPa ≤ 200 kPa (2,0 bar)	–	–	–	–	–	80[1]	–	100[1]
	> 200 kPa ≤ 300 kPa (3,0 bar)	–	–	–	–	–	78[1]	–	98[1]
	> 300 kPa ≤ 400 kPa (4,0 bar)	–	–	–	–	–	73[1]	–	93[1]
	> 400 kPa	–	–	–	–	–	70[1]	–	90[1]
2a)	AC windings of machines having outputs of less than 5 000 kW (or kVA), or having a core length of less than 1 m	60	65[1]	75	80[1]	80	85[1]	100	105[1]
2b)	DC field windings of a.c. and d.c. machines other than those in items 3 and 4	80	–	75	–	80	–	105	–
3	Field windings of turbo type machines having d.c. excitation	–	–	–	–	85	–	105	–
4a)	Low-resistance field windings of more than one layer and compensating windings	60	–	75	–	80	–	100	–
4b)	Single-layer windings with exposed bare or varnished metal surfaces[3]	65	–	80	–	90	–	110	–

[1] An adjustment for high-voltage a.c. windings may be applicable to these items, see table 8 item 4.

[2] This is the only item where the limit of temperature rise is dependant on hydrogen pressure.

[3] Also includes multi-layer field windings provided that the underlayers are each in contact with the circulating primary coolant.

Tableau 8 – Corrections aux limites des échauffements sur le site de fonctionnement des enroulements à refroidissement indirect pour tenir compte de conditions de fonctionnement et de caractéristiques assignées qui ne sont pas les conditions de référence

Point	Conditions de fonctionnement ou caractéristiques assignées		Corrections aux limites d'échauffement ($\Delta\theta$) des tableaux 6 et 7
1	Température maximale de l'air ambiant ou de l'air à l'entrée de la machine (θ_c)	0 °C ≤ θ_c ≤ 40 °C	Peuvent être augmentées par accord, mais cette augmentation ne doit dépasser ni la différence de température entre la température du fluide de refroidissement et 40 °C, ni un maximum de 30 K.
		40 °C < θ_c ≤ 60 °C	Réduites de la différence entre la température du fluide de refroidissement et 40 °C
		θ_c < 0 °C ou θ_c > 60 °C	Par accord
2	Température maximale de l'eau à l'entrée des hydro-réfrigérants (θ_w)	5 °C ≤ θ_w ≤ 25 °C	Augmentées de 10 K et peuvent être augmentées en plus d'une quantité ne dépassant pas la différence de température entre la température de l'eau de refroidissement et 25 °C.
		θ_w > 25 °C	Augmentées de 10 K et diminuées de la différence de température entre la température maximale de l'eau de refroidissement et 25 °C.
3	Altitude (H)	1 000 m < H ≤ 4 000 m et température maximale de l'air ambiant non spécifiée	Pas de correction. On doit admettre que la diminution du pouvoir de refroidissement résultant de l'altitude est compensée par une réduction de la température ambiante maximale au dessous de 40 °C et que les températures totales ne dépasseront en conséquence pas 40 °C plus les échauffements des tableaux 6 et 7[1)]
		H >4 000 m	Par accord
4	Tension assignée (U_N)	11 kV < U_N ≤ 17 kV	$\Delta\theta$, pour les indicateurs internes de température (IIT) doivent être réduites de 1 K par tranche de 1 kV (ou fraction de tranche) à partir de 11 kV jusqu'à 17 kV compris
		U_N > 17 kV	$\Delta\theta$, pour les indicateurs internes de température (IIT) doivent être réduites de 6 K et en plus réduites de 1,5 K par tranche de 1 kV (ou fraction de tranche) au-dessus de 17 kV
5[2)]	Caractéristiques assignées pour service temporaire (S2), avec puissance assignée inférieure à 5 000 kW (kVA)		Augmentées de 10 K
6[2)]	Caractéristiques assignées pour service non périodique (S9)		$\Delta\theta$, peuvent être dépassées pendant de courtes périodes lors du fonctionnement de la machine
7[2)]	Caractéristiques assignées pour service avec charges constantes distinctes (S10)		$\Delta\theta$, peuvent être dépassées pendant des périodes distinctes lors du fonctionnement de la machine.

[1)] En admettant que la réduction nécessaire de la température ambiante est de 1% des limites d'échauffement par tranche de 100 m au-dessus de 1 000 m, la température ambiante maximale présumée du site de fonctionnement, basée sur température ambiante maximale de 40 °C pour des altitudes inférieures ou égales à 1 000 m, sera celle qui est indiquée au tableau 9 (basé sur les limites d'échauffement des points 1b) et 1c) du tableau 6).

[2)] Uniquement pour les enroulements refroidis par air.

Table 8 – Adjustments to limits of temperature rise at the operating site of indirect cooled windings to take account of non-reference operating conditions and ratings

Item	Operating conditions or rating		Adjustment to limit of temperature rise (Δθ) in tables 6 and 7
1	Maximum temperature of ambient air or of the air at inlet to the machine (θ_c)	0 °C ≤ θ_c ≤ 40 °C	May be increased by agreement but this increase shall not exceed either the amount by which the coolant temperature is less than 40 °C, or a maximum of 30 K
		40 °C < θ_c ≤ 60 °C	Reduced by the amount by which the coolant temperature exceeds 40 °C
		θ_c < 0 °C or θ_c > 60 °C	By agreement
2	Maximum temperature of the water at inlet to water-cooled heat exchangers (θ_W)	5 °C ≤ θ_w ≤ 25 °C	Increased by 10 K and may be further increased by an amount not exceeding the amount by which the cooling temperature is less than 25 °C
		θ_w > 25 °C	Increased by 10 K and reduced by the amount by which the maximum cooling water temperature exceeds 25 °C
3	Altitude (H)	1 000 m < H ≤ 4 000 m and maximum ambient air temperature not specified	No adjustment. It shall be assumed that the reduced cooling resulting from altitude is compensated by a reduction of maximum ambient temperature below 40 °C and that the total temperature will therefore not exceed 40 °C plus the table 6 and 7 temperature rises[1)]
		H > 4 000 m	By agreement
4	Rated stator winding voltage (U_N)	11 kV < U_N ≤ 17 kV	Δθ for embedded temperature detectors (ETD) shall be reduced by 1 K for each 1 kV (or part thereof) from 11 kV up to and including 17 kV
		U_N > 17 kV	Δθ for embedded temperature detectors (ETD) shall be reduced by 6 K plus 1,5 K for each 1 kV (or part thereof) above 17 kV
5[2)]	Rating for short-time duty (S2), with rated output less than 5 000 kW (kVA)		Increased by 10 K
6[2)]	Rating for non-periodic duty (S9)		Δθ may be exceeded for short periods during the operation of the machine
7[2)]	Rating for duty with discrete loads (S10)		Δθ may be exceeded for discrete periods during the operation of the machine

[1)] Assuming the necessary decrease in ambient temperature is 1 % of the limiting rises for every 100 m of altitude above 1 000 m, the assumed maximum ambient air temperature at the operating site based on a 40 °C maximum ambient temperature for altitudes less than 1 000 m will be as shown in table 9 (based on the limiting rises for items 1b) and 1c) of table 6).

[2)] For air-cooled windings only.

Tableau 9 – Températures ambiantes maximales présumées

Altitude m	**Classification thermique**				
	A	E	B	F	H
	Température °C				
1000	40	40	40	40	40
2000	34	33	32	30	28
3000	28	26	24	19	15
4000	22	19	16	9	3

7.10.2 Enroulements à refroidissement direct

Les températures aux conditions de référence ne doivent pas excéder les limites données au tableau 11.

Pour des conditions différentes de fonctionnement sur site, les limites doivent être corrigées selon le tableau 12.

Si les conditions de fonctionnement sur site d'essai diffèrent de celles sur site de fonctionnement, les limites corrigées données au tableau 13 doivent s'appliquer au site d'essai.

Si les limites corrigées données au tableau 13 conduisent à des températures au site d'essai que le constructeur considère être excessives, la méthode d'essai et les limites doivent faire l'objet d'un accord.

7.10.3 Corrections pour tenir compte de la pureté de l'hydrogène au cours de l'essai

Pour les enroulements à refroidissement direct ou indirect par hydrogène, aucune correction ne doit être effectuée sur les limites d'échauffement ou de température totale, si la proportion de l'hydrogène est comprise entre 95 % et 100 %.

7.10.4 Enroulements continuellement fermés sur eux-mêmes, circuits magnétiques et tous éléments de structure (à l'exclusion des paliers), qu'ils soient ou non en contact direct avec une isolation

L'échauffement ou la température ne doit pas être préjudiciable à l'isolation de cette partie ou de toute autre partie avoisinante.

7.10.5 Collecteurs et bagues, ouverts ou enfermés, et leurs balais et porte-balais

La température ou l'échauffement de tout collecteur, bague, balai ou porte-balais ne doit pas être préjudiciable à l'isolation de cette partie ou de toute autre partie avoisinante.

La température ou l'échauffement d'un collecteur ou de bagues ne doit pas dépasser le niveau qui permet d'assurer le passage du courant dans toute la plage de fonctionnement, pour la combinaison de la qualité des balais et du matériau du collecteur ou des bagues.

Table 9 – Assumed maximum ambient temperature

Altitude m	Thermal class				
	A	E	B	F	H
	Temperature °C				
1000	40	40	40	40	40
2000	34	33	32	30	28
3000	28	26	24	19	15
4000	22	19	16	9	3

7.10.2 Direct cooled windings

Temperatures under reference conditions shall not exceed the limits given in table 11.

For other operating site conditions the limits shall be adjusted according to table 12.

If conditions at the test site differ from those at the operating site, the adjusted limits given in table 13 shall apply at the test site.

If the adjusted limits given in table 13 lead to temperatures at the test site which the manufacturer considers to be excessive, the testing procedure and the limits shall be agreed.

7.10.3 Adjustments to take account of hydrogen purity on test

For windings directly or indirectly cooled by hydrogen, no adjustment shall be made to limits of temperature rise or of total temperature if the proportion of hydrogen in the coolant is between 95 % and 100 %.

7.10.4 Permanently short-circuited windings, magnetic cores and all structural components (other than bearings) whether or not in contact with insulation

The temperature rise or the temperature shall not be detrimental to the insulation of that part or to any other part adjacent to it.

7.10.5 Commutators and sliprings, open or enclosed and their brushes and brushgear

The temperature rise or temperature of any commutator, slipring, brush or brushgear shall not be detrimental to the insulation of that part or any adjacent part.

The temperature rise or temperature of a commutator or slipring shall not exceed that at which the combination of brush grade and commutator or slipring material can handle the current over the full operating range.

Tableau 10 – Limites corrigées des échauffements sur le site d'essai ($\Delta\theta_T$) des enroulements à refroidissement indirect par air pour tenir compte des conditions de fonctionnement sur le site d'essai

Point	Conditions de fonctionnement sur le site d'essai		Limites corrigées sur le site d'essai $\Delta\theta_T$
1	Différence de température de fluide de refroidissement de référence entre site d'essai (θ_{cT}) et site de fonctionnement (θ_c)	Valeur absolue de ($\theta_c - \theta_{cT}$) ≤ 30 K	$\Delta\theta_T = \Delta\theta$
		Valeur absolue de ($\theta_c - \theta_{cT}$) > 30 K	Par accord
2	Différence d'altitude entre site d'essai (H_T) et site de fonctionnement (H)	1 000 m < H ≤ 4 000 m H_T < 1 000 m	$\Delta\theta_T = \Delta\theta\left(1 - \frac{H - 1\,000\ \text{m}}{10\,000\ \text{m}}\right)$
		H < 1 000 m 1 000 m < H_T ≤ 4 000 m	$\Delta\theta_T = \Delta\theta\left(1 + \frac{H_T - 1\,000\ \text{m}}{10\,000\ \text{m}}\right)$
		1 000 m < H ≤ 4 000 m 1 000 m < H_T ≤ 4 000 m	$\Delta\theta_T = \Delta\theta\left(1 + \frac{H_T - H}{10\,000\ \text{m}}\right)$
		H > 4 000 m ou H_T > 4 000 m	Par accord

1) $\Delta\theta$ est donné au tableau 6 et est corrigé, le cas échéant, conformément au tableau 8.

2) Si l'échauffement doit être mesuré au-dessus de la température de l'eau à son entrée dans le réfrigérant, en toute rigueur il faudrait tenir compte de l'effet de l'altitude sur la différence de température entre l'air et l'eau. Toutefois, pour la plupart des conceptions de réfrigérants, l'effet sera faible, la différence augmentant avec l'altitude au taux d'environ 2 K pour 1 000 m. Si une correction est nécessaire, il convient qu'elle fasse l'objet d'un accord.

Table 10 – Adjusted limits of temperature rise at the test site ($\Delta\theta_T$) for windings indirectly cooled by air to take account of test site operating conditions

Item	Test condition		Adjusted limit at test site $\Delta\theta_T$
1	Difference of reference coolant temperatures of test site (θ_{cT}) and operating site (θ_c)	Absolute value of $(\theta_c - \theta_{cT}) \leq 30$ K	$\Delta\theta_T = \Delta\theta$
		Absolute value of $(\theta_c - \theta_{cT}) > 30$ K	By agreement
2	Difference of altitudes of test site (H_T) and operating site (H)	1 000 m < $H \leq$ 4 000 m $H_T <$ 1 000 m	$\Delta\theta_T = \Delta\theta\left(1 - \frac{H - 1\,000\ \text{m}}{10\,000\ \text{m}}\right)$
		$H <$ 1 000 m 1 000 m < $H_T \leq$ 4 000 m	$\Delta\theta_T = \Delta\theta\left(1 + \frac{H_T - 1\,000\ \text{m}}{10\,000\ \text{m}}\right)$
		1 000 m < $H \leq$ 4 000 m 1 000 m < $H_T \leq$ 4 000 m	$\Delta\theta_T = \Delta\theta\left(1 + \frac{H_T - H}{10\,000\ \text{m}}\right)$
		$H >$ 4 000 m or $H_T >$ 4 000 m	By agreement

[1] $\Delta\theta$ is given in table 6 and adjusted if necessary in accordance with table 8.

[2] If temperature rise is to be measured above the temperature of the water where it enters the cooler, the effect of altitude on the temperature difference between air and water should strictly be allowed for. However, for most cooler designs, the effect will be small, the difference increasing with increasing altitude at the rate of roughly 2 K per 1 000 m. If an adjustment is necessary, it should be by agreement.

Tableau 11 – Limites des températures des enroulements à refroidissement direct et de leurs fluides de refroidissement

Classification thermique		**B**			**F**		
Méthode de mesure		**Thermomètre** °C	**Résistance** °C	**IIT** °C	**Thermomètre** °C	**Résistance** °C	**IIT** °C
Point	**Partie de la machine**						
1	Fluide de refroidissement à la sortie des enroulements à courant alternatif refroidis directement. Il est préférable d'utiliser ces valeurs, plutôt que celles du point 2, pour la définition des caractéristiques assignées						
1a)	Gaz (air, hydrogène, hélium, etc.)	110	–	–	130	–	–
1b)	Eau	90	–	–	90	–	–
2	Enroulements à courant alternatif						
2a) 2b)	Refroidis par un gaz Refroidis par un liquide	–	–	120[1)]	–	–	145[1)]
3	Enroulements d'excitation des turbo-machines						
3a)	Refroidis par un gaz sortant du rotor par le nombre suivant de zones de sortie [2)]						
	1 et 2	–	100	–	–	115	–
	3 et 4	–	105	–	–	120	–
	6	–	110	–	–	125	–
	8 à 14	–	115	–	–	130	–
	plus de 14	–	120	–	–	135	–
3b)	Refroidis par un liquide	L'observation des températures maximales du fluide de refroidissement spécifiées au point 1b) assure que la température aux points chauds de l'enroulement n'est pas excessive.					
4	Enroulements d'excitation à courant continu des machines à courant alternatif et à courant continu, autres que ceux du point 3						
4a)	Refroidis par un gaz	–	130	–	–	150	–
4b)	Refroidis par un liquide	L'observation des températures maximales du fluide de refroidissement spécifiées au point 1b) assure que la température aux points chauds de l'enroulement n'est pas excessive.					

[1)] Aucune correction n'est à effectuer à ces points dans le cas d'enroulements à courant alternatif à haute tension, voir point n° 2 du tableau 12.

[2)] La ventilation du rotor est caractérisée par le nombre de zones de sorties radiales sur toute la longueur du rotor. Les zones spéciales de sortie de fluide de refroidissement dans les têtes de bobines sont comptées à raison d'une sortie à chaque extrémité. La zone de sortie commune de deux courants dirigés en sens inverse est comptée pour deux zones.

Table 11 – Limits of temperature of directly cooled machines and their coolants

Thermal classification		B			F		
Method of measurement		Thermo-meter °C	Resistance °C	ETD °C	Thermo-meter °C	Resistance °C	ETD °C
Item	Part of the machine						
1	Coolant at the outlet of direct-cooled a.c. windings. These temperatures are preferred to the values given in item 2 as the basis of rating.						
1a)	Gas (air, hydrogen, helium, etc.)	110	–	–	130	–	–
1b)	Water	90	–	–	90	–	–
2	AC windings						
2a) 2b)	Gas cooled Liquid cooled	–	–	120[1)]	–	–	145[1)]
3	Field windings of turbine type machines						
3a)	Cooled by gas leaving the rotor through the following number of outlet regions [2)]						
	1 and 2	–	100	–	–	115	–
	3 and 4	–	105	–	–	120	–
	6	–	110	–	–	125	–
	8 to 14	–	115	–	–	130	–
	above 14	–	120	–	–	135	–
3b)	Liquid cooled	Observance of the maximum coolant temperature given in item 1b) will ensure that the hotspot temperature of the winding is not excessive.					
4	Field windings of a.c. and d.c. machines having d.c. excitation other than in item 3.						
4a)	Gas cooled	–	130	–	–	150	–
4b)	Liquid cooled	Observance of the maximum coolant temperature given in item 1b) will ensure that the hotspot temperature of the winding is not excessive.					

1) No adjustment in the case of high-voltage a.c. windings is applicable to these items, see table 12, item 2.

2) The rotor ventilation is classified by the number of radial outlet regions on the total length of the rotor. Special outlet regions for the coolant of the end windings are included as one outlet for each end. The common outlet region of two axially opposed flows is to be counted as two regions.

Tableau 12 – Corrections aux limites de température sur le site de fonctionnement pour les enroulements à refroidissement direct par air ou hydrogène pour tenir compte de conditions de fonctionnement et de caractéristiques assignées qui ne sont pas les conditions de référence

Point	Conditions de fonctionnement ou caractéristiques assignées		Corrections aux limites de température du tableau 11
1	Température du fluide de refroidissement de référence (θ_c)	0 °C ≤ θ_c ≤ 40 °C	Réduites de la différence entre 40 °C et θ_c. Cependant par accord, une réduction inférieure peut être effectuée, sous réserve que si θ_c < 10 °C, la réduction soit au moins égale à la différence entre 10 °C et θ_c
		40 °C < θ_c ≤ 60 °C	Pas de correction
		θ_c < 0 °C ou θ_c > 60 °C	Par accord
2	Tension assignée de l'enroulement statorique (U_N)	U_N > 11 kV	Pas de correction. Le débit de chaleur passe principalement vers le fluide de refroidissement à l'intérieur des conducteurs et non à travers l'isolation principale de l'enroulement.

Tableau 13 – Limites corrigées de température sur le site d'essai θ_T pour les enroulement à refroidissement direct par air pour tenir compte des conditions de fonctionnement sur le site d'essai

Point	Conditions de fonctionnement sur le site d'essai		Limites corrigées de température sur le site d'essai θ_T
1	Différence de température de fluide de refroidissement entre site d'essai (θ_{cT}) et site de fonctionnement (θ_c)	Valeur absolue de ($\theta_c - \theta_{cT}$) ≤ 30 K	$\theta_T = \theta$
		Valeur absolue de ($\theta_c - \theta_{cT}$) > 30 K	Par accord
2	Différence d'altitude entre site d'essai (H_T) et site de fonctionnement (H)	1 000 m < H ≤ 4 000 m H_T < 1 000 m	$\theta_T = (\theta - \theta_c)\left(1 - \frac{H - 1\,000\ \text{m}}{10\,000\ \text{m}}\right) + \theta_{cT}$
		H < 1 000 m 1 000 m < H_T ≤ 4 000 m	$\theta_T = (\theta - \theta_c)\left(1 + \frac{H_T - 1\,000\ \text{m}}{10\,000\ \text{m}}\right) + \theta_{cT}$
		1 000 m < H ≤ 4 000 m 1 000 m < H_T ≤ 4 000 m	$\theta_T = (\theta - \theta_c)\left(1 + \frac{H_T - H}{10\,000\ \text{m}}\right) + \theta_{cT}$
		H > 4 000 m ou H_T > 4 000 m	Par accord
NOTE θ est donné au tableau 11 et est corrigé, le cas échéant, conformément au tableau 12.			

Table 12 – Adjustments to limits of temperature at the operating site for windings directly cooled by air or hydrogen to take account of non-reference operating conditions and ratings

Item	Operating condition or rating		Adjustment to limit of temperature in table 11
1	Reference coolant temperature (θ_c)	0 °C ≤ θ_c ≤ 40 °C	Reduction by the amount of the difference between 40 °C and θ_c. However, by agreement, a smaller reduction may be applied, provided that for θ_c < 10 °C the reduction is made at least equal to the difference between 10 °C and θ_c.
		40 °C < θ_c ≤ 60 °C	No adjustment
		θ_c < 0 °C or θ_c > 60 °C	By agreement
2	Rated stator winding voltage (U_N)	U_N > 11 kV	No adjustment The heat flow is mainly towards the coolant inside the conductors and not through the main insulation of the winding.

Table 13 – Adjusted limits of temperature at the test site θ_T for windings directly cooled by air to take account of test site operating conditions

Item	Test condition		Adjusted limit of temperature at test site θ_T
1	Difference of reference coolant temperatures of test site (θ_{cT}) and operating site (θ_c)	Absolute value of ($\theta_c - \theta_{cT}$) ≤ 30 K	$\theta_T = \theta$
		Absolute value of ($\theta_c - \theta_{cT}$) > 30 K	By agreement
2	Difference of altitudes of test site (H_T) and operating site (H)	1 000 m < H ≤ 4 000 m H_T < 1 000 m	$\theta_T = (\theta - \theta_c)\left(1 - \frac{H - 1\,000\ \text{m}}{10\,000\ \text{m}}\right) + \theta_{cT}$
		H < 1 000 m 1 000 m < H_T ≤ 4 000 m	$\theta_T = (\theta - \theta_c)\left(1 + \frac{H_T - 1\,000\ \text{m}}{10\,000\ \text{m}}\right) + \theta_{cT}$
		1 000 m < H ≤ 4 000 m 1 000 m < H_T ≤ 4 000 m	$\theta_T = (\theta - \theta_c)\left(1 + \frac{H_T - H}{10\,000\ \text{m}}\right) + \theta_{cT}$
		H > 4 000 m or H_T > 4 000 m	By agreement
NOTE θ is given in table 11 and adjusted if necessary in accordance with table 12.			

Section 8: Autres caractéristiques de fonctionnement et essais

8.1 Essais de tension de tenue

Une tension d'essai telle que définie ci–après doit être appliquée entre les enroulements soumis à l'essai et la carcasse de la machine à laquelle sont reliés le circuit magnétique et les enroulements non soumis à l'essai. L'essai ne doit être effectué que sur une machine neuve et terminée, dont toutes les parties sont en place dans des conditions équivalentes aux conditions normales de fonctionnement; il doit être effectué dans l'atelier du constructeur ou après montage sur site. Si un essai d'échauffement est effectué, l'essai de tension de tenue doit être effectué immédiatement après cet essai.

Dans le cas de machines polyphasées de tension assignée supérieure à 1 kV, dont les deux extrémités de chaque phase sont individuellement accessibles, la tension d'essai doit être appliquée entre chaque phase et la carcasse, à laquelle sont reliés le circuit magnétique et les autres phases et enroulements non soumis à l'essai.

Sauf exception ci–dessous, la tension d'essai doit être à fréquence industrielle et de forme pratiquement sinusoïdale. La valeur finale de la tension d'essai doit être conforme au tableau 14. Toutefois, pour les machines de tension assignée égale ou supérieure à 6 kV, lorsque la disponibilité d'une installation d'essai à fréquence industrielle n'existe pas et après accord, l'essai peut être effectué en tension continue, à un niveau égal à 1,7 fois la valeur efficace spécifiée au tableau 14.

NOTE Il est reconnu que, lors d'un essai en tension continue, la distribution de potentiel de surface le long de l'isolation des développantes et les mécanismes de vieillissement sont différents de ceux en tension alternative.

L'essai doit être commencé avec une tension ne dépassant pas la moitié de la pleine tension d'essai. La tension est ensuite augmentée jusqu'à la pleine tension d'essai, d'une manière progressive ou par degrés ne dépassant pas 5 % de la pleine valeur, la durée de l'augmentation de la tension depuis la moitié jusqu'à la pleine valeur n'étant pas inférieure à 10 s. La pleine tension d'essai est alors maintenue pendant 1 min à la valeur spécifiée dans le tableau 14. Il ne doit pas y avoir de défaut (voir la CEI 60060-1) pendant cette séquence.

Lors des essais individuels des machines construites en série de puissance inférieure ou égale à 5 kW (ou kVA), l'essai de 1 min peut être remplacé par un essai d'environ 5 s à la tension normale d'essai spécifiée dans le tableau 14, ou d'environ 1 s à 120 % de la tension normale d'essai du tableau 14, la tension d'essai étant appliquée au moyen de pointes.

L'essai à haute tension effectué à pleine tension sur les enroulements lors de la réception ne doit pas être répété. Si, toutefois, un second essai est effectué sur demande de l'acheteur, après un séchage supplémentaire si cela est jugé nécessaire, la tension d'essai doit être égale à 80 % de la tension spécifiée dans le tableau 14.

Pour les moteurs à courant continu alimentés par convertisseurs statiques de puissance, on doit utiliser, pour déterminer la tension d'essai du tableau 14, la tension continue du moteur ou la valeur efficace de la tension alternative assignée entre phases aux bornes d'entrée du convertisseur statique de puissance, selon la valeur la plus élevée.

Les enroulements entièrement rebobinés doivent être essayés à la pleine valeur prévue pour les machines neuves.

Si un utilisateur et un réparateur ont convenu d'effectuer des essais de tension de tenue dans des cas de rebobinage partiel des enroulements ou de révision d'une machine, il est recommandé de procéder comme suit:

a) Les enroulements partiellement rebobinés sont essayés à 75 % de la tension d'essai prévue pour une machine neuve. Avant l'essai, la partie ancienne de l'enroulement, doit être soigneusement nettoyée et séchée.

Section 8: Other performance and tests

8.1 Withstand voltage test

A test voltage, as specified below, shall be applied between the windings under test and the frame of the machine, with the core and the windings not under test connected to the frame. It shall be applied only to a new and completed machine with all its parts in place under conditions equivalent to normal working conditions and shall be carried out at the manufacturer's works or after erection on site. When a thermal test is carried out, the withstand voltage test shall be carried out immediately after that test.

In the case of polyphase machines with rated voltage above 1 kV having both ends of each phase individually accessible, the test voltage shall be applied between each phase and the frame, with the core and the other phases and windings not under test connected to the frame.

Except as stated below, the test voltage shall be of power frequency and as near as possible to a sine wave form. The final value of the voltage shall be in accordance with table 14. However, for machines with a rated voltage 6 kV or greater, when power frequency equipment is not available, then by agreement a d.c. test may be carried out at a voltage 1,7 times the r.m.s. value given in table 14.

NOTE It is recognized that, during a d.c. test, the surface potential distribution along the end winding insulation and the ageing mechanisms are different from those occurring during an a.c. test.

The test shall be commenced at a voltage not exceeding half of the full test voltage. The voltage shall then be increased to the full value, steadily or in steps of not more than 5 % of the full value, the time allowed for the voltage increase from half to full value being not less than 10 s. The full test voltage shall then be maintained for 1 min in accordance with the value as specified in table 14. There shall be no failure (see IEC 60060-1) during this period.

During the routine testing of quantity produced machines up to 5 kW (or kVA), the 1 min test may be replaced by a test of approximately 5 s at the normal test voltage in table 14 or of approximately 1 s at 120 % of the normal test voltage in table 14, the test voltage being applied by means of prods.

The high-voltage test at full voltage made on the windings on acceptance shall not be repeated. If, however, a second test is made at the request of the purchaser, after further drying if considered necessary, the test voltage shall be 80 % of the voltage specified in table 14.

To determine the test voltage from table 14 for d.c. motors supplied by static power converters, the direct voltage of the motor or the r.m.s. phase-to-phase value of the rated alternating voltage at the input terminals of the static power converter shall be used, whichever is the greater.

Completely rewound windings shall be tested at the full test voltage for new machines.

When a user and a repair contractor have agreed to carry out withstand voltage tests in cases where windings have been partially rewound or in the case of an overhauled machine, the following procedure is recommended:

a) Partially rewound windings are tested at 75 % of the test voltage for a new machine. Before the test, the old part of the winding shall be carefully cleaned and dried.

b) Les machines révisées sont soumises, après nettoyage et séchage, à un essai à une tension égale à 1,5 fois la tension assignée, avec un minimum de 1 000 V si la tension assignée est égale ou supérieure à 100 V et un minimum de 500 V si la tension assignée est inférieure à 100 V.

Tableau 14 – Essais de tension de tenue

Point	Machine ou élément de la machine	Tension d'essai (valeur efficace)
1	Enroulements isolés de machines tournantes de puissance assignée inférieure à 1 kW (ou kVA) et de tension assignée inférieure à 100 V à l'exception de ceux des points 4 à 8	500 V + deux fois la tension assignée
2	Enroulements isolés de machines tournantes de puissance assignée inférieure à 10 000 kW (ou kVA) à l'exception de ceux des points 1 et 4 à 8[2)]	1 000 V + deux fois la tension assignée avec un minimum de 1 500 V[1)]
3	Enroulements isolés de machines tournantes de puissance assignée égale ou supérieure à 10 000 kW (ou kVA) à l'exception de ceux des points 4 à 8[2)]	
	Tension assignée[1)] – inférieure ou égale à 24 000 V – supérieure à 24 000 V	 1 000 V + deux fois la tension assignée Soumis à accord
4	Enroulements d'excitation séparée des machines à courant continu	1 000 V + deux fois la tension assignée maximale d'excitation avec un minimum de 1 500 V
5	Enroulements d'excitation des génératrices synchrones, des moteurs synchrones et des compensateurs synchrones	
5a)	Tension assignée d'excitation – inférieure ou égale à 500 V – supérieure à 500 V	 Dix fois la tension assignée d'excitation avec un minimum de 1 500 V 4 000 V + deux fois la tension assignée d'excitation
5b)	Si la machine est destinée à démarrer avec l'enroulement inducteur court-circuité ou fermé sur une résistance de valeur inférieure à dix fois la résistance de l'enroulement	Dix fois la tension assignée d'excitation avec un minimum de 1 500 V et un maximum de 3 500 V
5c)	Si la machine est destinée à démarrer soit avec l'enroulement inducteur fermé sur une résistance de valeur égale ou supérieure à dix fois la résistance de l'enroulement, soit avec les enroulements d'excitation en circuit ouvert avec ou sans diviseur de champ	1 000 V + deux fois la valeur maximale de la tension efficace qui peut se produire, dans les conditions de démarrage spécifiées, entre les bornes de l'enroulement d'excitation ou, dans le cas d'un enroulement d'excitation sectionné, entre les bornes de toute section, avec un minimum de 1 500 V[3)]
6	Enroulements secondaires (habituellement rotors) des moteurs à induction ou des moteurs à induction synchronisés non court-circuités en permanence (destinés par exemple à démarrer par rhéostats)	
6a)	Pour moteurs non réversibles ou pour moteurs réversibles à partir de l'arrêt seulement	1 000 V + deux fois la tension en circuit ouvert à l'arrêt, mesurée entre les bagues ou les bornes secondaires avec la tension assignée appliquée aux enroulements primaires
6b)	Pour les moteurs qui peuvent être inversés ou freinés en inversant l'alimentation primaire lorsque le moteur est en fonctionnement	1 000 V + quatre fois la tension secondaire en circuit ouvert à l'arrêt comme défini au point 6a)

b) Overhauled machines, after cleaning and drying, are subjected to a test at a voltage equal to 1,5 times the rated voltage, with a minimum of 1 000 V if the rated voltage is equal to or greater than 100 V and a minimum of 500 V if the rated voltage is less than 100 V.

Table 14 – Withstand voltage tests

Item	Machine or part	Test voltage (r.m.s.)
1	Insulated windings of rotating machines of rated output less than 1 kW (or kVA) and of rated voltage less than 100 V with the exception of those in Items 4 to 8	500 V + twice the rated voltage
2	Insulated windings of rotating machines of rated output less than 10 000 kW (or kVA) with the exception of those in Item 1 and Items 4 to 8 [2)]	1 000 V + twice the rated voltage with a minimum of 1500 V[1)]
3	Insulated windings of rotating machines of rated output 10 000 kW (or kVA) or more with the exception of those in Items 4 to 8 [2)] Rated voltage[1)]: - up to and including 24 000 V - above 24 000 V	 1 000 V + twice the rated voltage Subject to agreement
4	Separately excited field windings of d.c. machines	1 000 V + twice the maximum rated circuit voltage with a minimum of 1 500 V
5	Field windings of synchronous generators, synchronous motors and synchronous condensers.	
5a)	Rated field voltage: - up to, and including 500 V, - above 500 V.	 Ten times the rated field voltage with a minimum of 1 500 V 4 000 V + twice the rated field voltage
5b)	When a machine is intended to be started with the field winding short-circuited or connected across a resistance of value less than ten times the resistance of the winding	Ten times the rated field voltage with a minimum of 1 500 V and a maximum of 3 500 V.
5c)	When the machine is intended to be started either with the field winding connected across a resistance of value equal to, or more than, ten times the resistance of the winding, or with the field windings on open circuit with or without a field-dividing switch	1 000 V + twice the maximum value of the r.m.s. voltage, which can occur under the specified starting conditions, between the terminals of the field winding, or in the case of a sectionalized field winding between the terminals of any section, with a minimum of 1 500 V[3)]
6	Secondary (usually rotor) windings of induction motors or synchronous induction motors if not permanently short-circuited (e.g. if intended for rheostatic starting)	
6a)	For non-reversing motors or motors reversible from standstill only	1 000 V + twice the open-circuit standstill voltage as measured between slip-rings or secondary terminals with rated voltage applied to the primary windings
6b)	For motors to be reversed or braked by reversing the primary supply while the motor is running	1 000 V + four times the open-circuit standstill secondary voltage as defined in Item 6a)

Tableau 14 *(fin)*

Point	Machine ou élément de la machine	Tension d'essai (valeur efficace)
7	Excitatrices (sauf exceptions ci-dessous)	Comme les enroulements auxquels elles sont connectées
	Exception 1 – excitatrices des moteurs synchronisés (y compris les moteurs à induction synchrones) lorsqu'elles sont mises à la terre ou déconnectées des enroulements d'excitation pendant le démarrage	1 000 V + deux fois la tension assignée de l'excitatrice avec un minimum de 1500 V
	Exception 2 – enroulement à excitation séparée des excitatrices (voir point 4)	
8	Ensemble de machines et d'appareils électriquement reliés	Il est recommandé d'éviter si possible la répétition des essais des points 1 à 7, mais si l'essai est fait sur un ensemble de machines et d'appareils dont chacun a déjà subi un essai de tension de tenue, la tension d'essai appliquée à un tel ensemble connecté électriquement ne doit pas dépasser 80 % de la tension la plus basse applicable à l'un des éléments individuels de l'ensemble [4)]

[1)] Dans le cas d'enroulements diphasés ayant une borne commune, la tension dans la formule sera la plus haute tension en valeur efficace qui apparaît entre deux bornes quelconques pendant le fonctionnement.

[2)] L'essai diélectrique des machines à isolation graduée fera l'objet d'un accord.

[3)] La tension qui s'établit aux bornes des enroulements d'excitation ou de leurs sections, dans les conditions de démarrage spécifiées, peut être mesurée à une tension d'alimentation réduite appropriée; la tension ainsi mesurée sera augmentée dans le rapport de la tension de démarrage spécifiée à la tension d'alimentation de l'essai.

[4)] Pour les enroulements d'une ou plusieurs machines qui sont reliés ensemble électriquement, la tension à considérer est la tension maximale qui s'établit par rapport à la terre.

8.2 Surintensité occasionnelle

8.2.1 Généralités

La possibilité de surintensité des machines tournantes est donnée afin de coordonner ces machines à des dispositifs de commande et de protection. Des essais pour démontrer ces possibilités ne sont pas une prescription de la présente norme. L'effet d'échauffement dans les enroulements de la machine varie approximativement comme le produit du temps par le carré du courant. Un courant supérieur au courant assigné provoque une élévation de température. Sauf accord contraire, on peut supposer que la machine ne sera mise en fonctionnement à ces surintensités spécifiées que pendant quelques courtes périodes au cours de sa durée de vie. Si une machine à courant alternatif doit être utilisée à la fois comme génératrice et comme moteur, il est recommandé que la surintensité soit l'objet d'un accord.

NOTE Pour les machines synchrones, l'aptitude à fonctionner avec composante inverse de courant en régime de défaut est indiquée en 6.2.3.

8.2.2 Alternateurs

Les alternateurs dont la puissance assignée est inférieure ou égale à 1 200 MVA doivent être capables de supporter un courant égal à 1,5 fois le courant assigné pendant au moins 30 s.

Les alternateurs dont la puissance assignée est supérieure à 1 200 MVA doivent être capables de supporter un courant égal à 1,5 fois le courant assigné pendant une période qui doit faire l'objet d'un accord, mais cette période ne doit pas être inférieure à 15 s.

Table 14 *(concluded)*

Item	Machine or part	Test voltage (r.m.s.)
7	Exciters (except as below)	As for the windings to which they are connected
	Exception 1: Exciters of synchronous motors (including synchronous induction motors) if connected to earth or disconnected from the field windings during starting	1 000 V + twice the rated exciter voltage, with a minimum of 1 500 V
	Exception 2: Separately excited field windings of exciters (see Item 4)	
8	Electrically interconnected machines and apparatus	A repetition of the tests in items 1 to 7 above should be avoided if possible, but if a test is performed on a group of machines and apparatus, each having previously passed its withstand voltage test, the test voltage to be applied to such an electrically connected arrangement shall be 80 % of the lowest test voltage appropriate for any individual piece of the arrangement [4)]

[1)] For two-phase windings having one terminal in common, the voltage in the formula shall be the highest r.m.s. voltage arising between any two terminals during operation.

[2)] High-voltage tests on machines having graded insulation should be the subject of agreement.

[3)] The voltage occurring between the terminals of the field windings, or sections thereof, under the specified starting conditions, may be measured at any convenient reduced supply voltage, and the voltage so measured shall be increased in the ratio of the specified starting supply voltage to the test supply voltage.

[4)] For windings of one or more machines connected together electrically, the voltage to be considered is the maximum voltage that occurs in relation to earth.

8.2 Occasional excess current

8.2.1 General

The excess current capability of rotating machines is given for the purpose of co-ordinating these machines with control and protective devices. Tests to demonstrate these capabilities are not a requirement of this standard. The heating effect in the machine windings varies approximately as the product of the time and the square of the current. A current in excess of the rated current will result in increased temperature. Unless otherwise agreed, it can be assumed that the machine will not be operated at the excess currents specified for more than a few short periods during the lifetime of the machine. When an a.c. machine is to be used as both a generator and a motor, the excess current capability should be the subject of agreement.

NOTE For the capability of synchronous machines concerning the occasional negative-sequence component of current under fault conditions, see 6.2.3.

8.2.2 Generators

AC generators having rated outputs not exceeding 1 200 MVA shall be capable of withstanding a current equal to 1,5 times the rated current for not less than 30 s.

AC generators having rated outputs above 1 200 MVA shall be capable of withstanding a current equal to 1,5 times the rated current for a period which shall be agreed, but this period shall be not less than 15 s.

8.2.3 Moteurs à courant alternatif (sauf les moteurs à collecteur)

Les moteurs triphasés à courant alternatif dont la puissance assignée est inférieure ou égale à 315 kW et dont la tension assignée est inférieure ou égale à 1 kV doivent être capables de supporter un courant égal à 1,5 fois le courant assigné pendant au moins 2 min.

NOTE Pour les moteurs triphasés de puissance assignée supérieure à 315 kW et pour tous les moteurs monophasés, aucune surintensité occasionnelle n'est spécifiée.

8.2.4 Machines à collecteur

Une machine à collecteur doit être capable de supporter, pendant 60 s, 1,5 fois le courant assigné dans la combinaison appropriée des conditions suivantes:

a) vitesse:

1) moteur à courant continu: vitesse la plus élevée à pleine excitation;
2) génératrice à courant continu: vitesse assignée;
3) moteur à collecteur à courant alternatif: vitesse la plus élevée à pleine excitation;

b) tension d'induit: celle correspondant à la vitesse spécifiée.

8.3 Excès momentané de couple des moteurs

8.3.1 Moteurs à induction polyphasés et moteurs à courant continu (sauf les moteurs qui font l'objet de 8.3.2)

Les moteurs doivent, quels que soient leur service et leur réalisation, être capables de supporter, pendant 15 s, sans calage ni changement brusque de vitesse (sous une augmentation graduelle de couple) un excès du couple de 60 % de leur valeur assignée, la tension et la fréquence (moteurs à induction) étant maintenues à leurs valeurs assignées.

NOTE Pour certains moteurs fabriqués conformément à la CEI 60034-12, des couples plus importants sont nécessaires.

Pour les moteurs à courant continu, le couple doit être exprimé en termes de surintensité; voir 8.2.4.

Les moteurs pour service type S9 doivent être capables de supporter momentanément un excès de couple déterminé conformément au service spécifié.

NOTE Pour une détermination approchée des variations de température dues à l'évolution des pertes en fonction du courant, la constante de temps thermique équivalente, déterminée conformément à 7.8, peut être utilisée. De plus, dans le cas d'une machine à collecteur, il convient de prêter attention aux limites de possibilité de commutation.

8.3.2 Moteurs à induction pour applications particulières

Les moteurs destinés à des applications particulières qui exigent un couple élevé (par exemple pour les appareils de levage) doivent faire l'objet d'un accord.

Pour les moteurs à induction à cage spécialement prévus pour assurer au démarrage un courant inférieur à 4,5 fois le courant assigné, l'excès de couple peut être inférieur à 60 % de la valeur indiquée en 8.3.1, mais doit être au moins égal à 50 % de cette valeur.

Dans le cas des moteurs à induction de type spécial ayant des propriétés intrinsèques spéciales de démarrage, par exemple les moteurs destinés au fonctionnement à fréquence variable ou les moteurs à induction alimentés par convertisseurs statiques, la valeur de l'excès de couple doit faire l'objet d'un accord.

8.2.3 AC motors (except commutator motors)

Three-phase a.c. motors having rated outputs not exceeding 315 kW and rated voltages not exceeding 1 kV shall be capable of withstanding a current equal to 1,5 times the rated current for not less than 2 min.

NOTE For three-phase motors having rated outputs above 315 kW and all single-phase motors, no occasional excess current is specified.

8.2.4 Commutator machines

A commutator machine shall be capable of withstanding, for 60 s, 1,5 times rated current under the appropriate combination of conditions as follows:

a) speed:
   1) d.c. motor: highest full-field speed;
   2) d.c. generator: rated speed;
   3) a.c. commutator motor: highest full-field speed;

b) armature voltage: that corresponding to the specified speed;

8.3 Momentary excess torque for motors

8.3.1 Polyphase induction motors and d.c. motors (excluding motors in 8.3.2)

The motors shall, whatever their duty and construction, be capable of withstanding for 15 s, without stalling or abrupt change in speed (under gradual increase of torque), an excess torque of at least 60 % of their rated torque, the voltage and frequency (induction motors) being maintained at their rated value.

NOTE Higher torques are required for some motors manufactured according to IEC 60034-12.

For d.c. motors, the torque shall be expressed in terms of overload current; see 8.2.4.

Motors for duty type S9 shall be capable of withstanding momentarily an excess torque determined according to the duty specified.

NOTE For an approximate determination of the changes in temperature due to the course of the current-related losses, the thermal equivalent time constant, determined according to 7.8 may be used. In addition, in the case of a commutator machine, attention should be given to the limits of commutation capability.

8.3.2 Induction motors for specific applications

Motors intended for specific applications that require a high torque (for example for hoisting) shall be the subject of agreement.

For cage-type induction motors specially designed to ensure a starting current less than 4,5 times the rated current, the excess torque can be below the figure of 60 % given in 8.3.1, but not less than 50 %.

In the case of special types of induction motors with special inherent starting properties, for example motors intended for use at variable frequency or induction motors supplied from static converters, the value of the excess torque shall be the subject of agreement.

8.3.3 Moteurs synchrones polyphasés

Sauf accord contraire, un moteur synchrone polyphasé doit, quel que soit son service, être capable de supporter pendant 15 s, sans perte de synchronisme, l'excès de couple spécifié ci-dessous, l'excitation étant maintenue à la valeur qui correspond à la charge assignée. Dans le cas d'une excitation à réglage automatique, les limites de couple doivent avoir les mêmes valeurs, le dispositif d'excitation fonctionnant dans des conditions normales:

– moteurs asynchrones synchronisés (à rotor bobiné): excès de couple 35 %;
– moteurs synchrones (à rotor cylindrique): excès de couple 35 %;
– moteurs synchrones (à pôles saillants): excès de couple 50 %.

8.3.4 Autres moteurs

L'excès momentané de couple des moteurs monophasés, à collecteur et autres, doit faire l'objet d'un accord.

8.4 Couple minimal pendant le démarrage

Sauf spécification contraire, le couple minimal pendant le démarrage sous pleine tension des moteurs à induction à cage ne doit pas être inférieur aux valeurs suivantes:

Moteurs triphasés à une seule vitesse:

– de puissance inférieure à 100 kW: 0,5 fois le couple assigné et 0,5 fois le couple à rotor bloqué;
– de puissance égale ou supérieure à 100 kW: 0,3 fois le couple assigné et 0,5 fois le couple à rotor bloqué;
– pour les moteurs à induction à cage de tension inférieure ou égale à 690 V, voir aussi la CEI 60034-12.

Moteurs monophasés et moteurs triphasés à plusieurs vitesses: 0,3 fois le couple assigné.

8.5 Vitesse de sécurité en fonctionnement des moteurs à induction à cage

Tous les moteurs triphasés à induction à cage à une seule vitesse ayant une désignation de la carcasse inférieure ou égale à 315 et pour des tensions d'alimentation inférieures ou égales à 690 V doivent être capables de fonctionnement continu sûr à des vitesses inférieures ou égales à la vitesse appropriée du tableau 15 sauf indication différente indiquée sur la plaque signalétique.

8.3.3 Polyphase synchronous motors

Unless otherwise agreed, a polyphase synchronous motor, irrespective of the duty, shall be capable of withstanding an excess torque as specified below for 15 s without falling out of synchronism, the excitation being maintained at the value corresponding to rated load. When automatic excitation is used, the limits of torque shall be the same values with the excitation equipment operating under normal conditions:

– synchronous (wound rotor) induction motors: 35 % excess torque;
– synchronous (cylindrical rotor) motors: 35 % excess torque;
– synchronous (salient pole) motors: 50 % excess torque.

8.3.4 Other motors

The momentary excess torque for single-phase, commutator and other motors shall be the subject of agreement.

8.4 Pull-up torque

Unless otherwise specified, the pull-up torque of cage induction motors under full voltage shall not be less than the following values:

Single-speed three-phase motors:

– for output less than 100 kW: 0,5 times the rated torque and 0,5 times the locked-rotor torque;
– for output equal to or greater than 100 kW: 0,3 times the rated torque and 0,5 times the locked-rotor torque;
– for cage induction motors for voltage up to and including 690 V, see also IEC 60034-12.

Single-phase and multi-speed three-phase motors: 0,3 times the rated torque.

8.5 Safe operating speed of cage induction motors

All three-phase single-speed cage induction motors of frame number up to and including 315 and for voltages up to and including 690 V shall be capable of safe continuous operation at speeds up to the appropriate speed given in table 15 unless otherwise stated on the rating plate.

Tableau 15 – Vitesse maximale de sécurité en fonctionnement (min^{-1}) des moteurs triphasés à induction à cage, à une seule vitesse, pour des tensions d'alimentation inférieures ou égales à 690 V

Désignation de la carcasse	2 pôles	4 pôles	6 pôles
≤ 100	5 200	3 600	2 400
112	5 200	3 600	2 400
132	4 500	2 700	2 400
160	4 500	2 700	2 400
180	4 500	2 700	2 400
200	4 500	2 300	1 800
225	3 600	2 300	1 800
250	3 600	2 300	1 800
280	3 600	2 300	1 800
315	3 600	2 300	1 800

NOTE En cas de fonctionnement à des vitesses supérieures à la vitesse assignée, par exemple en cas d'utilisation avec commande de vitesse réglable, les niveaux de bruit et de vibration augmenteront. Il se peut que l'utilisateur ait besoin d'affiner l'équilibrage du rotor du moteur pour un fonctionnement acceptable au-dessus de la vitesse assignée. La durée de vie des paliers peut être réduite. Il convient de porter attention à la périodicité du regraissage ou à la durée de vie de la graisse.

8.6 Survitesse

Les machines doivent être conçues de façon à supporter les vitesses spécifiées dans le tableau 16.

Un essai de survitesse n'est pas normalement considéré comme nécessaire, mais il peut être effectué si cela a été spécifié et a fait l'objet d'un accord (pour les turbo-alternateurs, voir également la CEI 60034-3). Un essai de survitesse doit être considéré comme satisfaisant si, à la suite de cet essai, on ne constate pas de déformation permanente anormale ni d'autres signes de faiblesse pouvant empêcher la machine de fonctionner normalement et si les enroulements rotoriques satisfont aux essais diélectriques spécifiés. La durée de tout essai de survitesse doit être de 2 min.

En raison d'un affaissement des jantes de rotor feuilletées, des pôles feuilletés maintenus par des cales ou par des boulons, etc., une légère augmentation permanente du diamètre est naturelle et ne doit pas être considérée comme une déformation anormale indiquant que la machine ne se prête pas à un fonctionnement normal.

Pendant les essais de réception d'un alternateur synchrone entraîné par une turbine hydraulique, la machine doit tourner à la vitesse qu'elle peut atteindre avec la protection contre la survitesse en fonction, de façon à permettre de vérifier que l'équilibrage est satisfaisant jusqu'à cette vitesse.

Table 15 – Maximum safe operating speed (min^{-1}) of three-phase single-speed cage induction motors for voltages up to and including 690 V

Frame number	2 pole	4 pole	6 pole
≤ 100	5 200	3 600	2 400
112	5 200	3 600	2 400
132	4 500	2 700	2 400
160	4 500	2 700	2 400
180	4 500	2 700	2 400
200	4 500	2 300	1 800
225	3 600	2 300	1 800
250	3 600	2 300	1 800
280	3 600	2 300	1 800
315	3 600	2 300	1 800

NOTE When operating at speeds above rated speed, for example, when used with adjustable speed controls, noise and vibration levels will increase. The user may require to fine balance of the motor rotor for acceptable operation above rated speed. Bearing life may be reduced. Attention should be paid to the regreasing intervals and the grease service life.

8.6 Overspeed

Machines shall be designed to withstand the speeds specified in table 16.

An overspeed test is not normally considered necessary but can be performed when this is specified and has been agreed. (For turbine-type a.c. generators, see also IEC 60034-3.) An overspeed test shall be considered as satisfactory if no permanent abnormal deformation is apparent subsequently, and no other weakness is detected which would prevent the machine from operating normally, and provided the rotor windings after the test comply with the required dielectric tests. The duration of any overspeed test shall be 2 min.

Due to settling of laminated rotor rims, laminated poles held by wedges or by bolts etc., a minute permanent increase in the diameter is natural, and not to be considered as an abnormal deformation indicating that the machine is not suitable for normal operation.

During commissioning of a hydraulic-turbine driven synchronous generator, the machine shall be driven at the speed it can reach with the overspeed protection operating, so as to ascertain that the balance is satisfactory up to that speed.

Tableau 16 – Survitesses

Point	Type de machines	Prescription de survitesse
1	Machines à courant alternatif Toutes les machines autres que celles qui sont spécifiées ci-après:	 1,2 fois la vitesse assignée maximale
1a)	Alternateurs entraînés par une turbine hydraulique et machines auxiliaires de tous types couplées directement (électriquement ou mécaniquement) à la machine principale	Sauf spécification contraire, vitesse d'emballement du groupe, mais au moins 1,2 fois la vitesse assignée maximale
1b)	Machines pouvant, dans certaines circonstances être entraînées par la charge	Vitesse d'emballement spécifiée du groupe, mais au moins 1,2 fois la vitesse maximale
1c)	Moteurs série et moteurs universels	1,1 fois la vitesse à vide à la tension assignée. Pour les moteurs liés à la charge d'une manière telle qu'ils ne peuvent s'en dissocier accidentellement, l'expression «vitesse à vide» doit être interprétée «vitesse correspondant à la charge la plus faible possible»
1d)	Moteurs triphasés à induction à cage, à une seule vitesse selon l'article 8.5	1,2 fois la vitesse maximale de sécurité en fonctionnement
2	Machines à courant continu	
2a)	Moteurs à excitation shunt ou séparée	1,2 fois la vitesse assignée maximale, ou 1,15 fois la vitesse à vide correspondante la plus grande des deux valeurs
2b)	Moteurs à excitation composée ayant une plage de vitesse inférieure ou égale à 35 %	1,2 fois la vitesse assignée maximale ou 1,15 fois la vitesse à vide correspondante sans toutefois dépasser 1,5 fois la vitesse assignée maximale la plus grande des deux valeurs
2c)	Moteurs à excitation composée ayant une plage de vitesses supérieure à 35 % et moteurs à excitation série	Le constructeur doit attribuer une vitesse maximale de sécurité en fonctionnement qui sera marquée sur la plaque signalétique. La survitesse de ces moteurs sera égale à 1,1 fois cette vitesse maximale de sécurité en fonctionnement. Ce marquage est inutile si la survitesse correspond à 1,1 fois la vitesse à vide à la tension assignée
2d)	Moteurs à excitation par aimant permanent	Survitesse comme spécifiée au point 2a) sauf si le moteur a aussi un enroulement en série; dans ce cas, il doit pouvoir supporter les survitesses spécifiées points 2b) et 2c) selon les cas
2e)	Génératrices	1,2 fois la vitesse assignée

8.7 Courant de court-circuit des machines synchrones

Sauf spécification contraire, la valeur de crête du courant de court-circuit des machines synchrones, comprenant les turbo-machines non couvertes par la CEI 60034-3, dans le cas de court-circuit sur toutes les phases en fonctionnement sous la tension assignée, ne doit pas dépasser 15 fois la valeur de crête ou 21 fois la valeur efficace du courant assigné.

La vérification peut être effectuée par le calcul ou par un essai sous une tension au moins égale à 0,5 fois la tension assignée.

Table 16 – Overspeeds

Item	Machine type	Overspeed
1	AC machines All machines other than those specified below:	 1,2 times the maximum rated speed
1a)	Water-turbine driven generators, and any auxiliary machines connected directly (electrically or mechanically) to the main machine	Unless otherwise specified, the runaway speed of the set but not less than 1,2 times the maximum rated speed
1b)	Machines which may under certain circumstances be driven by the load	The specified runaway speed of the set but not less than 1,2 times the maximum rated speed.
1c)	Series and universal motors	1,1 times the no-load speed at rated voltage. For motors integrally attached to loads that cannot become accidentally disconnected, the words 'no-load speed' shall be interpreted to mean the lightest load condition possible with the load
1d)	Three-phase single-speed cage induction motors according to clause 8.5	1,2 times the maximum safe operating speed
2	DC machines	
2a)	Shunt and separately excited motor	1,2 times the highest rated speed or 1,15 times the corresponding no-load speed, whichever is greater
2b)	Compound excited motors having speed regulation of 35 % or less	1,2 times the higher rated speed or 1,15 times the corresponding no-load speed, whichever is greater but not exceeding 1,5 times the highest rated speed
2c)	Compound excited motors having speed regulation greater than 35 % and series motors	The manufacturer shall assign a maximum safe operating speed which shall be marked on the rating plate. The overspeed for these motors shall be 1,1 times the maximum safe operating speed. The safe operating speed marking is not required on motors that are capable of an overspeed of 1,1 times the no-load speed at rated voltage
2d)	Permanent-magnet excited motors	Overspeed as specified in Item 2a) unless the motor has a series winding and, in such a case, they shall withstand the overspeeds specified in Items 2b) or 2c) as appropriate
2e)	Generators	1,2 times the rated speed

8.7 Short-circuit current for synchronous machines

Unless otherwise specified, the peak value of the short-circuit current for synchronous machines, including turbine-type machines not covered by IEC 60034-3, in the case of short circuit on all phases during operation at rated voltage, shall not exceed 15 times the peak value or 21 times the r.m.s. value of the rated current.

Verification may be carried out by calculation or by means of a test at a voltage of 0,5 times the rated voltage or above.

8.8 Epreuve de tenue au court-circuit des machines synchrones

L'essai de court-circuit triphasé des machines synchrones n'est effectué que sur demande de l'acheteur. Dans ce cas, l'essai doit être effectué sur la machine en marche à vide avec une excitation correspondant, sauf accord contraire, à la tension assignée. L'essai ne doit pas être effectué avec une excitation supérieure à celle qui correspond à 1,05 fois la tension assignée à vide.

L'excitation d'essai ainsi déterminée peut être réduite selon accord pour tenir compte de l'impédance du transformateur qui peut être interposé entre les machines et le réseau. Dans ce dernier cas, il pourra également être accepté que l'essai soit effectué sur le site de fonctionnement avec le dispositif de surexcitation en service. Le court-circuit doit être maintenu pendant 3 s.

L'essai est jugé satisfaisant si aucune déformation nuisible ne se produit et si les prescriptions de l'essai diélectrique par tension appliquée (voir 8.1, tableau 14) sont satisfaites après l'essai de court-circuit. Pour les turbo-machines triphasées, voir CEI 60034-3.

8.9 Essai de commutation pour machines à collecteur

Une machine à courant continu ou à courant alternatif comportant un collecteur doit être capable de fonctionner de la marche à vide à la marche en surintensité ou excès de couple spécifiée aux articles 8.2 et 8.3, sans dommage permanent à la surface du collecteur ou des balais et sans étincelles dangereuses, les balais restant calés dans la même position. Si possible, l'essai de commutation doit être effectué à chaud.

8.10 Facteur harmonique téléphonique (FHT) pour machines synchrones

8.10.1 Généralités

Les prescriptions du présent paragraphe ne s'appliquent qu'aux machines synchrones de puissance assignée égale ou supérieure à 300 kW (ou kVA), destinées à être raccordées à des réseaux fonctionnant à des fréquences nominales de $16^{2}/_{3}$ Hz à 100 Hz inclus en vue de réduire au minimum les interférences entre les lignes de transport et les circuits adjacents.

8.10.2 Limites

Lorsqu'il est vérifié en circuit ouvert à la vitesse et à la tension assignées, le facteur harmonique téléphonique (FHT) de la tension entre bornes de phase, mesuré conformément aux méthodes de 8.10.3 ne doit pas dépasser les valeurs suivantes:

Puissance assignée de la machine	*FHT*
300 kW (ou kVA) < $P_N \leq$ 1000 kW (ou kVA)	5 %
1000 kW (ou kVA) < $P_N \leq$ 5000 kW (ou kVA)	3 %
5000 kW (ou kVA) < P_N	1,5 %

NOTE 1 Il n'est pas spécifié de valeurs limites pour les harmoniques individuels car il est considéré que les machines qui satisfont aux conditions ci-dessus fonctionnent de façon satisfaisante.

NOTE 2 Lorsque la machine synchrone doit être raccordée au réseau de façon inhabituelle (par exemple lorsque le neutre de la machine est mis à la terre et que la machine n'est pas reliée au réseau par l'intermédiaire d'un transformateur), il est recommandé qu'il y ait accord concernant les prescriptions de la forme d'onde.

8.8 Short-circuit withstand test for synchronous machines

The three-phase short-circuit test for synchronous machines shall be carried out only at the request of the purchaser. In this case, the test shall be carriedout on the machine running on no-load with an excitation corresponding to the rated voltage unless otherwise agreed. The test shall not be carriedout with an excitation greater than that corresponding to 1,05 times the rated voltage at no load.

The test excitation, as determined, may be reduced by agreement, in order to take into account the impedance of the transformer which may be placed between the machines and the system. In this latter case, it may also be agreed that the test be made at the operating site with the over-excitation device in operation. The short circuit shall be maintained for 3 s.

The test is considered satisfactory if no harmful deformation occurs and if the requirements of the applied voltage dielectric test (see 8.1, table 14) are met after the short-circuit test. For three-phase turbine-type machines, see IEC 60034-3.

8.9 Commutation test for commutator machines

A d.c. or a.c. commutator machine shall be capable of operating from no-load to operation with the excess current or excess torque, specified in clauses 8.2 and 8.3 respectively, without permanent damage to the surface of the commutator or brushes and without injurious sparking, the brushes remaining in the same set position. If possible, the commutation test shall be performed in warm conditions.

8.10 Telephone harmonic factor (THF) for synchronous machines

8.10.1 General

The requirements of this subclause apply only to synchronous machines having rated outputs of 300 kW (or kVA) or more, intended for connection to power networks operating at nominal frequencies of $16^{2}/_{3}$ Hz to 100 Hz inclusive, with a view to minimizing interference between power lines and adjacent circuits.

8.10.2 Limits

When tested on open-circuit and at rated speed and voltage, the telephone harmonic factor (THF) of the line-to-line terminal voltage as measured according to the methods laid down in 8.10.3 shall not exceed the following values:

Rated output of the machine	*THF*
300 kW (or kVA) < $P_N \leq$ 1 000 kW (or kVA)	5 %
1 000 kW (or kVA) < $P_N \leq$ 5 000 kW (or kVA)	3 %
5 000 kW (or kVA) < P_N	1,5 %

NOTE 1 Limiting values of individual harmonics are not specified as it is considered that machines which meet the above requirements will be operationally satisfactory.

NOTE 2 Where the synchronous machine is to be connected to the system in an unusual manner (e.g., where the star point of the machine is connected to earth and the machine is not linked to the system via a transformer), the waveform requirements should be agreed.

8.10.3 Essais

Les machines synchrones à courant alternatif doivent être soumises à des essais de type ayant pour objet de vérifier leur conformité à 8.10.2. La gamme des fréquences de mesure doit couvrir tous les harmoniques de la fréquence assignée à 5 000 Hz.

On mesure soit le FHT directement à l'aide d'un appareil de mesure associé à un réseau spécialement établi à cet effet, soit chaque harmonique individuel, le FHT étant calculé à partir des valeurs mesurées par la formule suivante:

$$\text{FHT}\ (\%) = \frac{100}{U} \times \sqrt{E_1^2 \times \lambda_1^2 + E_2^2 \times \lambda_2^2 + E_3^2 \times \lambda_3^2 + \ldots\ldots E_n^2 \times \lambda_n^2}$$

où

E_n est la valeur efficace de l'harmonique de rang *n* de la tension entre bornes de phase;

U est la valeur efficace de la tension entre bornes de phase de la machine;

λ_n est le facteur de pondération pour la fréquence correspondant à l'harmonique de rang *n.*

Les valeurs numériques du facteur de pondération pour les différentes fréquences doivent être obtenues à partir du tableau 17; la courbe de la figure 13 peut être utilisée pour faciliter l'interpolation.

8.10.3 Tests

Type tests shall be carried out on a.c. machines to verify compliance with 8.10.2. The range of frequencies measured shall cover all harmonics from rated frequency up to 5 000 Hz.

Either the THF may be measured directly by means of a meter and associated network specially designed for the purpose, or each individual harmonic shall be measured and from the measured values the THF shall be computed using the following formula:

$$\mathrm{THF}\,(\%) = \frac{100}{U} \times \sqrt{E_1^2 \times \lambda_1^2 + E_2^2 \times \lambda_2^2 + E_3^2 \times \lambda_3^2 + \ldots\ldots E_n^2 \times \lambda_n^2}$$

where

E_n is the r.m.s. value of the nth harmonic of the line-to-line terminal voltage;

U is the r.m.s. value of the line-to-line terminal voltage of the machine;

λ_n is the weighting factor for frequency corresponding to the nth harmonic.

Numerical values of the weighting factor for different frequencies shall be obtained from table 17; the curve in figure 13 may be used as an aid to interpolation.

Tableau 17 – Facteurs de pondération

Fréquence Hz	**Facteur de pondération**		**Fréquence** Hz	**Facteur de pondération**
16,66	0,000 001 17		2 050	1,79

Section 9: Plaques signalétiques

9.1 Généralités

Toute machine électrique doit être munie d'une ou de plusieurs plaques signalétiques. Les plaques doivent être réalisées dans un matériau durable et être montées de façon sûre.

Les plaques signalétiques doivent de préférence être fixées sur la carcasse de la machine et être placées de façon à être facilement lisibles dans la position d'utilisation déterminée par le type de construction et les dispositions de montage de la machine. Si la machine électrique fait partie de l'équipement ou y est incorporée de telle manière que sa plaque signalétique ne soit pas facilement lisible, le constructeur doit sur demande fournir une seconde plaque à fixer sur l'équipement.

9.2 Marquage

Pour les machines de puissance assignée inférieure ou égale à 750 W (ou VA) et dont les dimensions ne relèvent pas du domaine de la CEI 60072, ainsi que pour les machines incorporées, pour usage spécial, de puissance assignée inférieure ou égale à 3 kW (ou kVA), les indications 1, 2, 11 et 12 doivent au moins figurer comme marquage minimal.

Dans tous les autres cas, la ou les plaques signalétiques doivent porter les indications de la liste ci-après, pour autant qu'elles sont applicables. Il n'est pas nécessaire que toutes les indications figurent sur la même plaque. Les symboles littéraux des unités et grandeurs doivent être conformes à la CEI 60027-1 et à la CEI 60027-4.

Si le constructeur donne plus d'informations, il n'est pas nécessaire de les porter sur la ou les plaques signalétiques.

Les indications sont numérotées pour en faciliter la référence, mais l'ordre dans lequel elles apparaissent sur la ou les plaques signalétiques n'est pas normalisé. Les indications peuvent être combinées de façon convenable.

1) Nom du constructeur ou marque
2) Numéro de série du constructeur ou marque d'identification

   NOTE Une marque d'identification unique peut être utilisée pour identifier chaque élément d'un groupe de machines qui ont fait l'objet de la même conception électrique et mécanique et sont produites en un lot unique utilisant la même technologie.
3) Information permettant d'identifier l'année de fabrication. Celle-ci doit être marquée sur la plaque signalétique ou donnée sur une feuille de données séparée à fournir avec la machine.

   NOTE Si cette information peut être obtenue du constructeur à partir des indications données au point 2, elle peut être omise à la fois de la plaque signalétique et de la feuille de données séparée.
4) Code machine du constructeur
5) Pour les machines à courant alternatif, nombre de phases
6) Référence numérique de la ou des normes de caractéristiques assignées et de caractéristiques de fonctionnement qui sont applicables (CEI 60034-X et/ou norme(s) nationale(s) équivalente(s)). Si CEI 60034 est indiqué, ceci implique la conformité avec toutes les normes correspondantes de la série 34 de la CEI.
7) Degré de protection procuré par les enveloppes (Code IP) conformément à la CEI 60034-5.
8) Classification thermique et limite de température ou d'échauffement (quand elle est inférieure à celle de la classification thermique) et, si nécessaire, méthode de mesure, suivie dans le cas d'une machine à hydroréfrigérant de «P» ou «S», selon que l'échauffement est mesuré par rapport au fluide de refroidissement respectivement primaire ou secondaire; voir l'article 7.2. Cette information, présentée éditorialement avec un trait de fraction oblique, doit être donnée à la fois pour le stator et pour le rotor si leurs classifications thermiques diffèrent.

Section 9: Rating plates

9.1 General

Every electrical machine shall be provided with a rating plate(s). The plates shall be made of durable material and be securely mounted.

The rating plate(s) shall preferably be mounted on the frame of the machine and be located so as to be easily legible in the position of use determined by the type of construction and mounting arrangement of the machine. If the electrical machine is so enclosed or incorporated in the equipment that its rating plate is not easily legible, the manufacturer shall, on request, supply a second plate to be mounted on the equipment.

9.2 Marking

For machines with rated outputs up to and including 750 W (or VA) and dimensions not covered by IEC 60072 and for special-purpose built-in machines with rated outputs up to and including 3 kW (or kVA), items 1, 2, 11 and 12 shall be marked as a minimum.

In all other cases, rating plate(s) shall be durably marked with the items in the following list, as far as they apply. The items need not all be on the same plate. Letter symbols for units and quantities shall be in accordance with IEC 60027-1 and IEC 60027-4.

If the manufacturer gives more information, this need not necessarily be marked on the rating plate(s).

The items are numbered for convenient reference, but the order in which they appear on the rating plate(s) is not standardized. Items may be suitably combined.

1) The manufacturer's name or mark.
2) The manufacturer's serial number, or identification mark.

   NOTE A single identification mark may be used to identify each member of a group of machines which are made to the same electrical and mechanical design and are produced in one batch using the same technology.

3) Information to identify the year of manufacture. This shall be marked on the rating plate or be given on a separate data sheet to be provided with the machine.

   NOTE If this information can be obtained from the manufacturer by quoting the data specified in item 2, it may be omitted from both the rating plate and the separate data sheet.

4) The manufacturer's machine code.
5) For a.c. machines, the number of phases.
6) The number(s) of the rating and performance standard(s) which are applicable (IEC 60034-X and/or equivalent national standard(s)). If IEC 60034 is marked, this implies compliance with all the other relevant standards of the IEC 60034 series.
7) The degree of protection provided by the enclosures (IP code) in accordance with IEC 60034-5.
8) The thermal classification and the limit of temperature or of temperature rise (when lower than that of the thermal classification) and, if necessary, the method of measurement, followed in the case of a machine with a water-cooled heat exchanger by 'P' or 'S', depending on whether the temperature rise is measured above the primary or secondary coolant respectively (see clause 7.2). This information shall be given for both stator and rotor (separated by a slash) when their thermal classifications differ.

9) Classe(s) de caractéristiques assignées de la machine, si celle-ci est conçue pour d'autres caractéristiques que celles pour service continu S1, voir 4.2.

10) Puissance(s) assignée(s) ou plage de puissance assignée.

11) Tension(s) assignée(s) ou plage de tension assignée.

12) Pour les machines à courant alternatif la fréquence assignée ou une plage de fréquence assignée.

Pour les moteurs universels, la fréquence assignée doit être suivie du symbole approprié:

par exemple ~ 50 Hz /⎓ ou c.a. 50 Hz/c.c.

13) Courant(s) assigné(s) ou plage de courant assigné.

14) Vitesse(s) assignée(s) ou plage de vitesse assignée.

15) Pour les machines à courant alternatif triphasé à plus de trois points de connexion, instructions pour le raccordement au moyen d'un schéma ou d'un texte. Ces instructions doivent soit figurer sur une plaque près de la boîte à bornes soit être fournies dans la boîte.

16) Survitesse admissible si différente de celle spécifiée à l'article 8.6,
ou
vitesse maximale de sécurité en fonctionnement si inférieure à celle spécifiée à l'article 8.5.

17) Pour les machines à courant continu à excitation séparée ou à excitation shunt et pour les machines synchrones, tension d'excitation assignée et courant d'excitation assigné.

18) Pour les machines à courant alternatif, facteur(s) de puissance assigné(s).

19) Pour les machines à induction à rotor bobiné, tension entre bagues à circuit ouvert et courant rotorique assignés.

20) Pour les moteurs à courant continu dont l'induit est prévu pour être alimenté par convertisseurs statiques de puissance, code d'identification du convertisseur statique de puissance conformément à la CEI 60971. En variante, pour des moteurs ne dépassant pas 5 kW, facteur de forme assigné et tension alternative assignée aux bornes d'entrée du convertisseur statique de puissance, si celle-ci est supérieure à la tension directe assignée du circuit d'induit du moteur.

21) Température maximale de l'air ambiant, si différente de 40 °C.

Température maximale de l'eau de refroidissement, si différente de 25 °C.

22) Température minimale de l'air ambiant, si différente de celle spécifiée en 5.4.

23) Altitude pour laquelle la machine est conçue (si supérieure à 1000 m au dessus du niveau de la mer).

24) Pour les machines refroidies par hydrogène, pression de l'hydrogène à la puissance assignée.

25) Lorsque spécifié, masse totale approchée de la machine, si supérieure à 30 kg.

26) Pour les machines prévues pour fonctionner dans un seul sens de rotation, sens de rotation, indiqué par une flèche. Il n'est pas nécessaire de placer cette flèche sur la plaque signalétique, mais elle doit être distinguée aisément.

Deux valeurs assignées différentes doivent être indiquées par X/Y et une plage de valeurs assignées doit être indiquée par X–Y (voir la CEI 61293).

Si l'enroulement d'une machine est partiellement ou totalement réparé ou modifié par une autre personne que le constructeur, une plaque supplémentaire doit être prévue pour indiquer le nom du réparateur, l'année de la réparation et les modifications effectuées.

9) The class(es) of rating of the machine if designed for other than rating for continuous running duty S1, see 4.2.

10) The rated output(s) or range of rated outputs.

11) The rated voltage(s) or range of rated voltage.

12) For a.c. machines the rated frequency or range of rated frequency.

    For universal motors, the rated frequency shall be followed by the appropriate symbol:

    e.g. ~ 50 Hz/⎓ or a.c. 50 Hz/d.c.

13) The rated current(s) or range of rated current.

14) The rated speed(s) or range of rated speed.

15) For three-phase a.c. machines with more than three connecting points, connecting instructions by means of a diagram or text. These instructions shall be on a plate mounted near the terminal box or be provided inside the box.

16) The permissible overspeed if other than specified in clause 8.6.

    or

    the maximum safe operating speed if less than in clause 8.5.

17) For d.c. machines with separate excitation or with shunt excitation and for synchronous machines, the rated field voltage and the rated field current.

18) For a.c. machines, the rated power factor(s).

19) For wound-rotor induction machines, the rated open-circuit voltage between slip-rings and the rated slip-ring current.

20) For d.c. motors with armatures intended to be supplied by static power converters, the identification code of the static power converter in accordance with IEC 60971. Alternatively for motors not exceeding 5 kW, the rated form factor and the rated alternating voltage at the input terminals of the static power converter, when this exceeds the rated direct voltage of the motor armature circuit.

21) The maximum ambient air temperature, if other than 40 °C.

    The maximum water coolant temperature, if other than 25 °C.

22) The minimum ambient air temperature if other than specified in 5.4.

23) The altitude for which the machine is designed (if exceeding 1 000 m above sea-level).

24) For hydrogen-cooled machines, the hydrogen pressure at rated output.

25) When specified, the approximate total mass of the machine, if exceeding 30 kg.

26) For machines suitable for operation in only one direction of rotation, the direction of rotation, indicated by an arrow. This arrow need not be on the rating plate, but it shall be easily visible.

Two different rated values shall be indicated by X/Y and a range of rated values shall be indicated by X–Y (see IEC 61293).

If the winding of a machine is partially or totally repaired or changed by other than the manufacturer, an additional plate shall be provided to indicate the repair contractor's name, the year of repair and the changes made.

Section 10: Prescriptions diverses

10.1 Mise à la terre des machines

Les machines doivent comporter des dispositifs permettant de raccorder un conducteur de protection ou un conducteur de terre, de tels dispositifs étant identifiés par le symbole ou la légende appropriés. Cette prescription ne s'applique pas aux machines munies d'une isolation supplémentaire, aux machines de tension assignée inférieure à 50 V en courant alternatif ou 120 V en courant continu (voir CEI 60364-4-41, article 411 et CEI 60449), ni aux machines à installer dans des ensembles à isolation supplémentaire.

Dans le cas des machines de tension assignée supérieure à 50 V en courant alternatif ou 120 V en courant continu, mais ne dépassant pas 1 000 V en courant alternatif ou 1 500 V en courant continu, la borne du conducteur de terre doit être située à proximité des bornes de raccordement des conducteurs de phase, à l'intérieur de la boîte de connexions éventuelle. Les machines de puissance assignée supérieure à 100 kW (ou kVA) doivent également comporter une borne de terre montée sur la carcasse.

Les machines de tension assignée supérieure à 1 000 V en courant alternatif ou 1 500 V en courant continu doivent avoir une borne de terre sur la carcasse, par exemple une languette de fer et, en outre, le cas échéant, un point de connexion à l'intérieur de la boîte de connexions pour raccorder une gaine conductrice de câble.

La borne de terre doit être conçue de manière à assurer une bonne liaison avec le conducteur de terre, sans détérioration du conducteur ou de la borne. Les parties conductrices accessibles qui ne font pas partie du circuit d'utilisation doivent être raccordées les unes aux autres et à la borne de terre, par une liaison électrique de bonne qualité. Si tous les paliers et l'enroulement rotorique d'une machine sont isolés, l'arbre doit être relié électriquement à la borne de terre, à moins d'un accord entre le constructeur et l'acheteur sur d'autres moyens de protection.

Si la boîte de connexions est équipée d'une borne de terre, le conducteur de terre est supposé être du même métal que les conducteurs de phase.

Si une borne de terre est placée sur la carcasse, le conducteur de terre peut, sur accord, être d'un autre métal (en acier par exemple). Dans ce cas, la conception de la borne doit être étudiée en tenant compte de la conductivité de l'âme du conducteur.

La borne de terre doit être conçue pour admettre un conducteur de terre de la section de l'âme conforme au tableau 18 ci-dessous. Si un câble plus gros est utilisé, il est recommandé que sa section se rapproche autant que possible d'une des autres valeurs de ce tableau.

Pour d'autres sections de conducteurs de phase, le conducteur de terre ou de protection doit avoir une section au moins équivalente à:

– celle du conducteur de phase pour des sections inférieures à 25 mm²;
– 25 mm² pour des sections comprises entre 25 mm² et 50 mm²;
– 50 % de celle du conducteur de phase pour des sections supérieures à 50 mm².

La borne de terre doit être identifiée conformément à la CEI 60445.

Section 10 : Miscellaneous requirements

10.1 Earthing of machines

Machines shall be provided with means for connecting a protective conductor or an earth conductor, such means being identified by the appropriate symbol or legend. This requirement does not apply to machines with supplementary insulation, to machines with rated voltages up to and including 50 V a.c. or 120 V d.c. (see IEC 60364-4-41, clause 411 and IEC 60449), or to machines for assembling in apparatus with supplementary insulation.

In the case of machines having rated voltages greater than 50 V a.c. or 120 V d.c., but not exceeding 1 000 V a.c. or 1 500 V d.c., the terminal for the earth conductor shall be situated in the vicinity of the terminals for the line conductors, being placed in the terminal box, if one is provided. Machines having rated outputs in excess of 100 kW (or kVA) shall have in addition an earth terminal fitted on the frame.

Machines for rated voltages greater than 1 000 V a.c. or 1 500 V d.c. shall have an earth terminal on the frame, for example an iron strap, and in addition, a means inside the terminal box for connecting a conducting cable sheath, if any.

The earth terminal shall be designed to ensure a good connection with the earth conductor without any damage to the conductor or terminal. Accessible conducting parts which are not part of the operating circuit shall have a good electrically conducting connection with each other and with the earth terminal. When all bearings and the rotor winding of a machine are insulated, the shaft shall be electrically connected to the earth terminal, unless the manufacturer and the purchaser agree to alternative means of protection.

When an earth terminal is provided in the terminal box, it shall be assumed that the earth conductor is made of the same metal as the live conductors.

When an earth terminal is provided on the frame, the earth conductor may, by agreement, be made of another metal (e.g. steel). In this case, in designing the terminal, proper consideration shall be given to the conductivity of the conductor.

The earth terminal shall be designed to accommodate an earth conductor of cross-sectional area in accordance with table 18. If an earth conductor larger than the size given in the table is used, it is recommended that it should correspond as nearly as possible to one of the other sizes listed.

For other cross-sectional areas of live conductors, the earth or protective conductor shall have a cross-sectional area at least equivalent to:

– that of the live conductor for cross-sectional areas less than 25 mm^2;
– 25 mm^2 for cross-sectional areas between 25 mm^2 and 50 mm^2;
– 50 % of that of the live conductor for cross-sectional areas exceeding 50 mm^2 .

The earth terminal shall be identified in accordance with IEC 60445.

When a machine shaft end is provided with one or more keyways, each shall be provided with a full key of normal shape and length.

Section 11: Tolérances

11 Tolérances

Les tolérances doivent être conformes aux spécifications du tableau 19.

Tableau 19 – Nomenclature des tolérances sur les valeurs des grandeurs

Point	Article	Tolérance
1	Rendement η	
1a)	Par sommation des pertes:	
	– machines de puissance inférieure ou égale à 50 kW (ou kVA)	–15 % de $(1 - \eta)$
	– machines de puissance supérieure à 50 kW (ou kVA)	–10 % de $(1 - \eta)$
1b)	Par mesurage des pertes totales	–15 % de $(1 - \eta)$
2	Pertes totales	+10 % des pertes totales
3	Facteur de puissance, cos ϕ, pour les machines à induction	$-1/6\ (1 - \cos\phi)$ Minimum de la valeur absolue 0,02 Maximum de la valeur absolue 0,07
4	Vitesse des moteurs à courant continu (à pleine charge et à la température de fonctionnement)	
4a)	Moteurs à excitation shunt ou séparée	$1000\ P_N/n_N{}^* < 0{,}67$ ± 15 % $0{,}67 \leq 1000\ P_N/n_N < 2{,}5$ ± 10 % $2{,}5 \leq 1000\ P_N/n_N < 10$ ± 7,5 % $10 \leq 1000\ P_N/n_N$ ± 5 %
4b)	Moteurs à excitation série	$1000\ P_N/n_N < 0{,}67$ ± 20 % $0{,}67 \leq 1000\ P_N/n_N < 2{,}5$ ± 15 % $2{,}5 \leq 1000\ P_N/n_N < 10$ ± 10 % $10 \leq 1000\ P_N/n_N$ ± 7,5 %
4c)	Moteurs à excitation composée	Les tolérances sont les mêmes que celles du point 4b) sauf accord contraire
5	Variation de vitesse des moteurs shunt ou à excitation composée à courant continu (entre la charge nulle et la pleine charge)	±20 % de la variation garantie avec un minimum de ±2 % de la vitesse assignée
6	Variation de tension des génératrices à courant continu, à excitation shunt ou séparée, en tout point de la caractéristique	±20 % de la variation garantie en ce point
7	Variation de tension des génératrices à excitation composée (au facteur de puissance assigné dans le cas du courant alternatif)	±20 % de la variation de tension garantie avec un minimum de ±3 % de la tension assignée. (Cette tolérance s'applique à l'écart maximal, à une charge quelconque, entre la tension observée à cette charge et une droite tracée entre les points de la tension garantie à vide et en charge.)

Section 11: Tolerances

11 Tolerances

Tolerances shall be as specified in table 19.

Table 19 – Schedule of tolerances on values of quantities

Item	Quantity	Tolerance
1	Efficiency η	
1a)	By summation of losses:	
	– machines up to and including 50 kW (or kVA)	–15 % of $(1 - \eta)$
	– machines above 50 kW (or kVA)	–10 % of $(1 - \eta)$
1b)	By total loss measurement	–15 % of $(1 - \eta)$
2	Total losses	+10 % of the total losses
3	Power-factor, cos ϕ, for induction machines	–1/6 (1 – cos ϕ) Minimum absolute value 0,02 Maximum absolute value 0,07
4	Speed of d.c. motors (at full load and at working temperature)	
4a)	Shunt and separately excited motors	$1000\ P_N/n_N$* < 0,67 ± 15 % $0,67 \leq 1000\ P_N/n_N < 2,5$ ± 10 % $2,5 \leq 1000\ P_N/n_N < 10$ ± 7,5 % $10 \leq 1000\ P_N/n_N$ ± 5 %
4b)	Series motors	$1000\ P_N/n_N < 0,67$ ± 20 % $0,67 \leq 1000\ P_N/n_N < 2,5$ ± 15 % $2,5 \leq 1000\ P_N/n_N < 10$ ± 10 % $10 \leq 1000\ P_N/n_N$ ± 7,5 %
4c)	Compound excited motors	Tolerances as for item 4b) unless otherwise agreed
5	Variation of speed of d.c. shunt and compound excited motors (from no-load to full load)	±20 % of the guaranteed variation with a minimum of ±2 % of the rated speed
6	Inherent voltage regulation of d.c. generators, shunt or separately excited at any point on the characteristic	±20 % of the guaranteed regulation at that point
7	Inherent voltage regulation of compound excited generators (at the rated power-factor in the case of alternating current)	±20 % of the guaranteed regulation, with a minimum of ±3 % of the rated voltage. (This tolerance applies to the maximum deviation at any load between the observed voltage at that load and a straight line drawn between the points of guaranteed no-load and full-load voltage.)

Tableau 19 *(fin)*

Point	Article	Tolérance
8 a)	Glissement des moteurs à induction (à pleine charge et à la température de fonctionnement)	
	P_N < 1 kW	±30 % du glissement garanti
	P_N ≥ 1 kW	±20 % du glissement garanti
8 b)	Vitesse des moteurs à courant alternatif à collecteur à caractéristiques shunt (à pleine charge et à la température de fonctionnement)	– sur la vitesse la plus élevée: –3 % de la vitesse de synchronisme – sur la vitesse la moins élevée: +3 % de la vitesse de synchronisme
9	Courant à rotor bloqué des moteurs à induction à cage avec tout dispositif de démarrage spécifié	+20 % du courant garanti
10	Couple à rotor bloqué des moteurs à induction à cage	$^{+25}_{-15}$ % du couple garanti (+25 % peut être dépassé sur accord)
11	Couple minimal pendant le démarrage des moteurs à induction à cage	–15 % du couple garanti
12	Couple maximal pendant le démarrage des moteurs à induction (couple de décrochage)	–10 % du couple garanti sous réserve qu'après application de cette tolérance le couple reste égal ou supérieur à 1,6 ou 1,5 fois le couple assigné, voir 8.3.
13	Courant à rotor bloqué des moteurs synchrones	+20 % de la valeur garantie
14	Couple à rotor bloqué des moteurs synchrones	$^{+25}_{-15}$ % de la valeur garantie (+25 % peut être dépassé sur accord)
15	Couple de décrochage des moteurs synchrones	–10 % de la valeur garantie sous réserve qu'après application de cette tolérance le couple reste égal ou supérieur à 1,35 ou 1,5 fois le couple assigné, voir 8.3.3.
16	Valeur de crête du courant de court-circuit d'un alternateur dans des conditions spécifiées	±30 % de la valeur garantie
17	Courant de court-circuit permanent d'un alternateur dans des conditions spécifiées	±15 % de la valeur garantie
18	Moment d'inertie	± 10 % de la valeur garantie

NOTE 1 Lorsqu'une tolérance est spécifiée seulement dans un sens, la valeur n'est pas limitée dans l'autre sens.

NOTE 2 Des garanties ne sont pas nécessairement données sur toutes les grandeurs ou l'une quelconque d'entre celles indiquées dans le présent tableau. Les offres concernant des garanties sujettes à des tolérances devront le stipuler et les tolérances devront être conformes à ce tableau.

NOTE 3 L'attention est attirée sur les différentes interprétations du mot «garantie». Dans certains pays, on fait la différence entre les valeurs garanties et les valeurs caractéristiques ou valeurs déclarées.

NOTE 4 Les tolérances dépendent du rapport de puissance P_N en kW, à la vitesse assignée en min^{-1}.

Table 19 *(concluded)*

Point	Quantity	Tolerance
8 a)	Slip of induction motors (at full load and at working temperature)	
	P_N < 1 kW	±30 % of the guaranteed slip
	P_N ≥ 1 kW	±20 % of the guaranteed slip
8 b)	Speed of a.c. (commutator) motors with shunt characteristics (at full load and at working temperature)	– on the highest speed: –3 % of the synchronous speed – on the lowest speed: +3 % of the synchronous speed
9	Locked rotor current of cage induction motors with any specified starting apparatus	+20 % of the guaranteed current
10	Locked rotor torque of cage induction motors	$^{+25}_{-15}$ % of the guaranteed torque. (+25 % may be exceeded by agreement)
11	Pull-up torque of cage induction motors	–15 % of the guaranteed value
12	Breakdown torque of induction motors	–10 % of the guaranteed torque except that after allowing for this tolerance the torque shall be not less than 1,6 or 1,5 times the rated torque, see 8.3.
13	Locked rotor current of synchronous motors	+ 20 % of the guaranteed value
14	Locked rotor torque of synchronous motors	$^{+25}_{-15}$ % of the guaranteed value (+25 % may be exceeded by agreement)
15	Pull-out torque of synchronous motors	–10 % of the guaranteed value except that after allowing for this tolerance, the torque shall be not less than 1,35 or 1,5 times the rated torque, see 8.3.3.
16	Peak value of short-circuit current of an a.c. generator under specified conditions	±30 % of the guaranteed value
17	Steady short-circuit current of an a.c. generator at specified excitation	±15 % of the guaranteed value
18	Moment of inertia	±10 % of the guaranteed value

NOTE 1 When a tolerance is stated in only one direction, the value is not limited in the other direction.

NOTE 2 It is not intended that guarantees necessarily be given upon all or any of the quantities shown in this table. Tenders including guarantees subject to tolerances should so state, and the tolerances should be in accordance with this table.

NOTE 3 Attention is drawn to the different interpretations of the term "guarantee". In some countries a distinction is drawn between guaranteed values and typical or declared values.

NOTE 4 Tolerances depend on the ratio of rated output P_N, in kW, to rated speed in min^{-1}.

Section 12: Compatibilité électromagnétique (CEM)

12.1 Compatibilité électromagnétique (CEM)

Les prescriptions qui suivent sont applicables aux machines électriques tournantes de tension assignée ne dépassantpas 1 000 V (courant alternatif) ou 1 500 V (courant continu) et sont destinées à fonctionner selon les conditions spécifiées ci-dessous.

Les composants électroniques qui sont montés à l'intérieur de la machine électrique tournante et qui sont destinés pour son fonctionnement (par exemple les systèmes d'excitation tournants) font partie de la machine.

Les prescriptions qui sont applicables à un système d'entraînement final et à ses composants, par exemple un équipement électronique de puissance et de commande, des machines couplées, des appareils de contrôle, etc., qu'ils soient montés à l'intérieur ou à l'extérieur de la machine, sont hors du domaine d'application de cette norme.

Les prescriptions de la section 12 ne s’appliquent pas aux machines dont les caractéristiques de CEM sont notablement modifiées par les capotage et montage finals.

Les limites de la section 6 sont établies pour des conditions de fonctionnement en régime établi. Les régimes transitoires (tels que le démarrage) ne sont pas couverts par le présent article.

12.1.1 Limites d'immunité

Les limites d'immunité des machines à courant alternatif et des machines à courant continu aux variations et aux harmoniques de tension du système connecté, et les limites d'immunité des machines à courant alternatif polyphasées aux déséquilibres du système connecté sont données à la section 6.

12.1.2 Limites d'émission

NOTE Les limites dans les tableaux qui suivant sont tirées du CISPR 11 ou du CISPR 12.

12.1.2.1 Machines à induction

Quand elles sont reliées à un système conformément à la section 6, les machines à induction ne produisent pas de rayonnements perturbateurs supérieurs aux limites

– du tableau 19 pour les machines avec rotors à cage ou avec rotors bobinés munies d'un dispositif de levage des balais et de court-circuit des bagues; ou
– du tableau 20 pour les machines fonctionnant en permanence avec bagues et balais en contact.

Les émissions de conduction sont intrinsèquement bien inférieures aux limites données au tableau 19.

12.1.2.2 Machines synchrones

Quand elles sont reliées à un système conformément à la section 6, les machines synchrones ne produisent pas de rayonnements perturbateurs supérieurs aux limites du tableau 19, pour les machines sans bagues ni balais, ou aux limites du tableau 20 pour les machines avec bagues et balais.

L'émission de conduction à basse fréquence est couverte par 8.9. Les émissions de conduction à fréquences supérieures sont intrinsèquement bien inférieures aux limites données au tableau 19.

Section 12: Electromagnetic compatibility (EMC)

12.1 Electromagnetic compatibility (EMC)

The following requirements apply to rotating electrical machines with a rated voltage not exceeding 1 000 V a.c. or 1 500 V d.c., and which are intended for operation within the conditions specified below.

Electronic components mounted inside the rotating electrical machine and essential for its operation (for example rotating excitation devices) are part of the machine.

Requirements which are applicable to the final drive system and its components, for example power and control electronic equipment, coupled machines, monitoring devices, etc., whether mounted inside or outside the machine, are outside the scope of this standard.

The requirements of section 12 do not apply to machines when the EMC performance is significantly affected by the final enclosure and assembly.

The limitations of section 6 are fixed for steady-state operating conditions. Transients (such as starting) are not covered by this clause.

12.1.1 Immunity limits

The immunity limits of both a.c. and d.c. machines to variations and harmonics of the system voltage, and those of polyphase a.c. machines to unbalances of the connected system, are given in section 6.

12.1.2 Emission limits

NOTE The limits in the tables that follow are taken from CISPR 11 or CISPR 12.

12.1.2.1 Induction machines

When connected to a system according to section 6, induction machines do not produce radiated disturbances higher than the limits in

– table 19 for machines with cage rotors or with wound rotors having brush-lifting and short-circuiting devices; or

– table 20 for machines with continuously running slip-rings.

Conducted emissions are inherently much lower than the limits given in table 19.

12.1.2.2 Synchronous machines

When connected to a system according to section 6, synchronous machines do not radiate disturbances higher than the limits of table 19 for brushless designs or of table 20 for designs with slip-rings.

The conducted low-frequency emission is covered by 8.9. Conducted emissions of higher frequencies are inherently much lower than the limits given in table 19.

Tableau 19 – Limites des perturbations électromagnétiques pour les machines fonctionnant sans balais

	Plages de fréquences	Limites
Rayonnement perturbateur	30 MHz à 230 MHz	30 dB(µV/m) quasi crête, mesuré à 10 m de distance [1)]
	230 MHz à 1 000 MHz	37 dB(µV/m) quasi crête, mesuré à 10 m de distance [1)]
Conduction perturbatrice aux bornes d'alimentation à courant alternatif	0,15 MHz à 0,5 MHz Les limites diminuent proportionnellement avec le logarithme de la fréquence	66 à 56 dB(µV) quasi crête 56 à 46 dB(µV) moyenne
	0,5 MHz à 5 MHz	56 dB(µV) quasi crête 46 dB(µV) moyenne
	5 MHz à 30 MHz	60 dB(µV) quasi crête 50 dB(µV) moyenne
[1)] Peut être mesuré à une distance de 3 m, en augmentant les limites de 10 dB.		

12.1.2.3 Machines à collecteur

Les machines à courant continu, fonctionnant avec une tension lissée et les machines à collecteur à courant alternatif, fonctionnant sur un système conformément à la section 6, ne doivent pas rayonner de perturbations supérieures aux limites du tableau 20.

Les émissions de conduction des machines à collecteur à courant alternatif doivent être inférieures aux limites du tableau 20. Les émissions de conduction des machines à courant continu ne sont pas à considérer car ces machines ne sont pas directement reliées à l'alimentation à courant alternatif.

Tableau 20 – Limites des perturbatins électromagnétiques pour les machines fonctionnant avec balais

	Plages de fréquences	Limites
Rayonnement perturbateur	30 MHz à 230 MHz	30 dB(µV/m) quasi crête, mesuré à 30 m de distance [1)]
	230 MHz à 1 000 MHz	37 dB(µV/m) quasi crête, mesuré à 130 m de distance [1)]
Conduction perturbatrice aux bornes d'alimentation à courant alternatif	0,15 MHz à 0,5 MHz	79 dB(µV) quasi crête 66 dB(µV) moyenne
	0,5 MHz à 30 MHz	73 dB(µV) quasi crête 60 dB(µV) moyenne
[1)] Peut être mesuré à une distance de 10 m en augmentant les limites de 10 dB, ou à une distance de 3 m en augmentant les limites de 20 dB.		

12.1.3 Essais

12.1.3.1 Essais d'immunité

Des essais d'immunité ne sont pas exigés pour démontrer la conformité au présent article.

Table 19 – Electromagnetic disturbance limits for machines operating without brushes

	Frequency range	Limits
Radiated disturbance	30 MHz to 230 MHz	30 dB(μV/m) quasi peak, measured at 10 m distance[1)]
	230 MHz to 1 000 MHz	37 dB(μV/m) quasi peak, measured at 10 m distance[1)]
Conducted disturbance on a.c. supply terminals	0,15 MHz to 0,5 MHz Limits decrease linearly with logarithm frequency	66 to 56 dB(μV) quasi peak 56 to 46 dB(μV) average
	0,5 MHz to 5 MHz	56 dB(μV) quasi peak 46 dB(μV) average
	5 MHz to 30 MHz	60 dB(μV) quasi peak 50 dB(μV) average
[1)] May be measured at 3 m distance using the limits increased by 10 dB.		

12.1.2.3 Commutator machines

DC machines operating on a smooth voltage and a.c. commutator motors operating on a system according to section 6 shall not radiate disturbances which are above the limits of table 20.

Conducted emissions from a.c. commutator machines shall be below the levels of table 20. Conducted emissions from d.c. machines are irrelevant since these machines are not directly connected to the a.c. supply.

Table 20 – Electromagnetic disturbance limits for machines operating with brushes

	Frequency range	Limits
Radiated disturbance	30 MHz to 230 MHz	30 dB(μV/m) quasi peak, measured 30 m distance[1)]
	230 MHz to 1 000 MHz	37 dB(μV/m) quasi peak, measured 30 m distance[1)]
Conducted disturbance on a.c. supply terminals	0,15 MHz to 0,50 MHz	79 dB(μV) quasi peak 66 dB(μV) average
	0,50 MHz to 30 MHz	73 dB(μV) quasi peak 60 dB(μV) average
[1)] May be measured at 10 m distance using the limits increased by 10 dB or measured at 3 m distance using the limits increased by 20 dB.		

12.1.3 Tests

12.1.3.1 Immunity tests

Immunity tests are not required to demonstrate compliance with this clause.

12.1.3.2 Essais d'émission

Pour les machines synchrones de puissance supérieure ou égale à 300 kW (ou kVA), des essais de type d'émission de conduction à basse fréquence doivent être effectués pour vérifier la conformité à 8.9.2.

Pour les machines à collecteur à courant alternatif, des essais de type à vide doivent être effectués afin de vérifier la conformité à 12.1.2.3 pour l'émission de conduction et l'émission de rayonnement.

Pour les machines à collecteur à courant continu, des essais de type à vide ou à charge minimale possible doivent être effectués afin de vérifier la conformité à 12.1.2.3 pour l'émission de rayonnement.

Les essais doivent être conduits suivant le CISPR 11, le CISPR 14 et le CISPR 16, selon le cas.

Aucun autre essai n'est exigé afin de démontrer la conformité au présent article.

NOTE La mesure à vide se justifie par l'influence négligeable de la charge sur l'émission.

Section 13: Sécurité

13.1 Sécurité

Les machines tournantes conformes à la présente norme doivent satisfaire aux exigences de la CEI 60204-1, sauf spécification contraire dans la présente norme, et dans la mesure du possible, elles doivent également être conçues et construites selon la meilleure forme de conception internationalement acceptée, selon l'application.

NOTE Il est de la responsabilité du constructeur ou de l'assembleur de l'équipement incorporant des machines électriques de s'assurer que l'équipement complet est sûr.

Cela peut conduire à prendre en considération des normes de produits applicables telles que:

CEI 60079*: Matériel électrique pour atmosphères gazeuses,*

CEI 60335: *Sécurité des appareils électrodomestiques et analogues;*

et d'autres parties de la CEI 60034 y compris:

CEI 60034,5, CEI 60034-6, CEI 60034-7, CEI 60034-8, CEI 60034-9, CEI 60034-11, CEI 60034-12 et CEI 60034-14.

De plus, il peut être nécessaire de considérer la limitation de la température de surface et des caractéristiques similaires; voir par exemple la CEI 60335-1(1991), article 11: Echauffement.

12.1.3.2 Emission tests

For synchronous machines having outputs of 300 kW (or kVA) or more, type tests for conducted low-frequency emission shall be carried out to verify compliance with 8.9.2.

For a.c. commutator machines, type tests on no-load for conducted and radiated emission shall be carried out to verify compliance with 12.1.2.3.

For d.c. commutator machines, type tests on no-load or minimum possible load for radiated emission shall be carried out to verify compliance with 12.1.2.3.

The tests shall be carried out in accordance with CISPR 11, CISPR 14, and CISPR 16 as applicable.

No other tests are required to demonstrate compliance with this clause.

NOTE The measurement on no-load is justified by the negligible influence of load on the emission.

Section 13: Safety

13.1 Safety

Rotating machines in accordance with this standard shall comply with the requirements of IEC 60204-1 unless otherwise specified in this standard, and be designed and constructed as far as possible in accordance with internationally accepted best design practice, appropriate to the application.

NOTE It is the responsibility of the manufacturer or assembler of equipment incorporating electrical machines as components to ensure that the overall equipment is safe.

This may involve consideration of relevant product standards such as:

IEC 60079: *Electrical apparatus for explosive gas atmospheres,*

IEC 60335: *Safety of household and similar electrical appliances;*

and other parts of IEC 60034 including:

IEC 60034-5, IEC 60034-6, IEC 60034-7, IEC 60034-8, IEC 60034-9, IEC 60034-11, IEC 60034-12 and IEC 60034-14.

In addition, it may be necessary to consider limitation of the surface temperature and similar characteristics; see for example IEC 60335-1 (1991), clause 11: Heating.

Annexe A
(informative)

Guide pour l'application du service type S10 et pour l'obtention de la valeur relative de l'espérance de vie thermique TL

A.1 La charge de la machine équivaut à tout moment au service type S1 correspondant au paragraphe 3.2.1. Cependant, le cycle de charges peut comprendre d'autres charges que la charge assignée basée sur le service type S1. Un cycle de charges ne peut pas comprendre plus de quatre charges constantes distinctes (voir la figure 10).

A.2 Selon la valeur et la durée des différentes charges dans un cycle, l'espérance de vie relative de la machine basée sur le vieillissement thermique du système d'isolation peut se calculer avec l'équation suivante:

$$\frac{1}{TL} = \sum_{i=1}^{n} \Delta t_i \times 2^{\frac{\Delta\Theta_i}{k}}$$

où

TL est l'espérance de vie thermique en valeur relative par rapport à l'espérance de vie thermique dans le cas du service type S1 à la puissance assignée;

$\Delta\Theta_i$ est la différence entre l'échauffement de l'enroulement au cours des différentes charges dans un cycle et l'échauffement basé sur le service type S1 à la charge de référence;

Δt_i est la durée réduite (p.u.) d'une charge constante dans un cycle de charge;

k est l'augmentation d'échauffement en kelvins qui conduit à une réduction de 50 % de l'espérance de vie thermique du système d'isolation;

n est le nombre des valeurs distinctes de charges ($n \leq 4$).

A.3 La valeur de TL fait partie intégrante de l'identification précise de la classe de caractéristiques assignées.

A.4 La valeur de TL ne peut être déterminée que lorsque, en plus de l'information sur le cycle de charge d'après la figure 10, la valeur k du système d'isolation est connue. Cette valeur k doit être déterminée par expérimentation conformément à la CEI 60034-18 dans toute la plage de température couverte par le cycle de charge selon la figure 10.

A.5 On peut raisonnablement donner la valeur de TL sous la seule forme d'une valeur relative. On peut utiliser cette valeur pour établir approximativement la variation réelle de l'espérance de vie thermique par rapport à celle du service type S1 à la puissance assignée car on peut supposer, en considérant les différentes charges existantes dans un cycle, que les autres effets sur l'espérance de vie de la machine (par exemple contraintes diélectriques, influences du milieu) sont sensiblement les mêmes que ceux dans le cas du service type S1 à la puissance assignée.

A.6 Le constructeur de la machine est responsable de la compilation exacte des différents paramètres servant à déterminer la valeur TL.

Annex A
(informative)

Guidance for the application of duty type S10 and for establishing the value of relative thermal life expectancy TL

A.1 The load of the machine at any moment is equivalent to duty type S1 corresponding to 3.2.1. However, the load cycle may comprise loads other than the rated load based on duty type S1. One load cycle may comprise not more than four discrete constant loads, see figure 10.

A.2 Depending on the value and duration of the different loads within one cycle, the relative life expectancy of the machine based on the thermal ageing of the insulation system can be calculated by the following equation:

$$\frac{1}{TL} = \sum_{i=1}^{n} \Delta t_i \times 2^{\frac{\Delta\Theta_i}{k}}$$

where

TL is the relative thermal life expectancy related to the thermal life expectancy in case of duty type S1 with rated output;

$\Delta\Theta_i$ is the difference between the temperature rise of the winding at each of the various loads within one cycle and the temperature rise based upon duty type S1 with reference load;

Δt_i is the p.u. time of a constant load within a load cycle;

k is the increase in temperature rise in K, which leads to a shortening of the thermal life expectancy of the insulation system by 50 %;

n is the number of discrete values of load ($n \leq 4$).

A.3 The quantity TL is an integral part of the unambiguous identification of the class of rating.

A.4 The value of the quantity TL can be determined only when, in addition to information concerning the load cycle according to figure 10, the value k for the insulation system is known. This value k has to be determined by experiments in conformity with IEC 60034-18 for the whole temperature range within which the load cycle takes place according to figure 10.

A.5 TL can be stated sensibly as a relative value only. This value can be used by approximation to assess the real change in the machine thermal life expectancy as compared to duty type S1 with rated output, because it may be assumed that in consideration of the varying loads existing within a cycle the remaining influences over the lifetime of the machine (e.g. dielectric stress, environmental influences) are approximately the same as in the case of duty type S1 with rated output.

A.6 The manufacturer of the machine is responsible for the correct compilation of the various parameters for determining the value of TL.

Q1 Please report on **ONE STANDARD** and **ONE STANDARD ONLY**. Enter the exact number of the standard: *(e.g. 60601-1-1)*

.....

Q2 Please tell us in what capacity(ies) you bought the standard *(tick all that apply).* I am the/a:

purchasing agent ❑
librarian ❑
researcher ❑
design engineer ❑
safety engineer ❑
testing engineer ❑
marketing specialist ❑
other.....

Q3 I work for/in/as a: *(tick all that apply)*

manufacturing ❑
consultant ❑
government ❑
test/certification facility ❑
public utility ❑
education ❑
military ❑
other.....

Q4 This standard will be used for: *(tick all that apply)*

general reference ❑
product research ❑
product design/development ❑
specifications ❑
tenders ❑
quality assessment ❑
certification ❑
technical documentation ❑
thesis ❑
manufacturing ❑
other.....

Q5 This standard meets my needs: *(tick one)*

not at all ❑
nearly ❑
fairly well ❑
exactly ❑

Q6 If you ticked NOT AT ALL in Question 5 the reason is: *(tick all that apply)*

standard is out of date ❑
standard is incomplete ❑
standard is too academic ❑
standard is too superficial ❑
title is misleading ❑
I made the wrong choice ❑
other .....

Q7 Please assess the standard in the following categories, using the numbers:
(1) unacceptable,
(2) below average,
(3) average,
(4) above average,
(5) exceptional,
(6) not applicable

timeliness.....
quality of writing.....
technical contents.....
logic of arrangement of contents .....
tables, charts, graphs, figures.....
other .....

Q8 I read/use the: *(tick one)*

French text only ❑
English text only ❑
both English and French texts ❑

Q9 Please share any comment on any aspect of the IEC that you would like us to know:

.....
.....
.....
.....
.....
.....
.....

.....
.....

Enquête sur les normes

La CEI ambitionne de vous offrir les meilleures normes possibles. Pour nous assurer que nous continuons à répondre à votre attente, nous avons besoin de quelques renseignements de votre part. Nous vous demandons simplement de consacrer un instant pour répondre au questionnaire ci-après et de nous le retourner par fax au +41 22 919 03 00 ou par courrier à l'adresse ci-dessous. Merci !

Centre du Service Clientèle (CSC)

Commission Electrotechnique Internationale

Q1 Veuillez ne mentionner qu'**UNE SEULE NORME** et indiquer son numéro exact: (*ex. 60601-1-1)*

.....

Q2 En tant qu'acheteur de cette norme, quelle est votre fonction?
(cochez tout ce qui convient)
Je suis le/un:

agent d'un service d'achat ❑
bibliothécaire ❑
chercheur ❑
ingénieur concepteur ❑
ingénieur sécurité ❑
ingénieur d'essais ❑
spécialiste en marketing ❑
autre(s).....

Q3 Je travaille:
(cochez tout ce qui convient)

dans l'industrie ❑
comme consultant ❑
pour un gouvernement ❑
pour un organisme d'essais/ certification ❑
dans un service public ❑
dans l'enseignement ❑
comme militaire ❑
autre(s).....

Q4 Cette norme sera utilisée pour/comme
(cochez tout ce qui convient)

ouvrage de référence ❑
une recherche de produit ❑
une étude/développement de produit ❑
des spécifications ❑
des soumissions ❑
une évaluation de la qualité ❑
une certification ❑
une documentation technique ❑
une thèse ❑
la fabrication ❑
autre(s).....

Q5 Cette norme répond-elle à vos besoins:
(une seule réponse)

pas du tout ❑
à peu près ❑
assez bien ❑
parfaitement ❑

Q6 Si vous avez répondu PAS DU TOUT à Q5, c'est pour la/les raison(s) suivantes:
(cochez tout ce qui convient)

la norme a besoin d'être révisée ❑
la norme est incomplète ❑
la norme est trop théorique ❑
la norme est trop superficielle ❑
le titre est équivoque ❑
je n'ai pas fait le bon choix ❑
autre(s) .....

Q7 Veuillez évaluer chacun des critères ci-dessous en utilisant les chiffres
(1) inacceptable,
(2) au-dessous de la moyenne,
(3) moyen,
(4) au-dessus de la moyenne,
(5) exceptionnel,
(6) sans objet

publication en temps opportun .....
qualité de la rédaction.....
contenu technique .....
disposition logique du contenu .....
tableaux, diagrammes, graphiques, figures.....
autre(s) .....

Q8 Je lis/utilise: *(une seule réponse)*

uniquement le texte français ❑
uniquement le texte anglais ❑
les textes anglais et français ❑

Q9 Veuillez nous faire part de vos observations éventuelles sur la CEI:

.....
.....
.....
.....
.....
.....

AVANT-PROPOS

Le présent amendement a été établi par le comité d'études 2 de la CEI: Machines tournantes.

Le texte de cet amendement est issu des documents suivants:

FDIS	Rapport de vote
2/956/FDIS	2/984/RVD

Le rapport de vote indiqué dans le tableau ci-dessus donne toute information sur le vote ayant abouti à l'approbation de cet amendement.

_____

INTRODUCTION

Cet amendement 2 est publié en parallèle avec un amendement équivalent 1 à la CEI 60034-1 (10e édition) de façon que le contenu technique des deux éditions reste le même.

Page 88

18.3 *Surintensité occasionnelle des machines à collecteur*

Remplacer la première phrase de ce paragraphe par la phrase suivante:

Une machine à collecteur doit être capable de supporter, pendant 60 s, 1,5 fois le courant assigné dans la combinaison appropriée des conditions suivantes:

Supprimer le point c).

FOREWORD

This amendment has been prepared by IEC technical committee 2: Rotating machinery.

The text of this amendment is based on the following documents:

FDIS	Report on voting
2/956/FDIS	2/984/RVD

Full information on the voting for the approval of this amendment can be found in the report on voting indicated in the above table.

_____

INTRODUCTION

This amendment 2 is issued in parallel with an equivalent amendment 1 to IEC 60034-1 (tenth edition) in order that the technical content of the two editions remains the same.

Page 11

1.2 *Normative references*

Insert, in the existing list, the titles of the following standards:

IEC 60204-1: 1992, *Electrical equipment of industrial machines – Part 1: General requirements*

CISPR 11: 1990, *Limits and methods of measurement of electromagnetic disturbance characteristics of industrial, scientific and medical (ISM) radio-frequency equipment*

CISPR 14: 1993, *Limits and methods of measurement of radio disturbance characteristics of electrical motor–operated and thermal appliances for household and similar purposes, electric tools and electric apparatus*

CISPR 16: *Specification for radio disturbance and immunity measuring apparatus and methods*

Page 89

18.3 *Occasional excess current for commutator machines*

Replace the first sentence of this subclause by the following:

A commutator machine shall be capable of withstanding, for 60 s, 1,5 times rated current under the appropriate combination of conditions as follows:

Delete item c).

19.1 *Moteurs à induction polyphasés et moteurs à courant continu (sauf les moteurs qui font l'objet de 19.2)*

Remplacer le premier alinéa de ce paragraphe par l'alinéa suivant:

Les moteurs doivent, quels que soient leur service et leur réalisation, être capables de supporter, pendant 15 s, sans calage ni changement brusque de vitesse (sous une augmentation graduelle de couple), un excès du couple d'au moins 60 % de leurs valeurs assignées, la tension et la fréquence (moteurs à induction) étant maintenues à leurs valeurs assignées.

NOTE – Pour certains moteurs fabriqués conformément à la CEI 60034-12, des couples plus importants sont nécessaires.

Pour les moteurs à courant continu, le couple doit être exprimé en termes de surintensité; voir 18.3.

Page 114

Ajouter les deux nouvelles sections suivantes:

Section 14: Compatibilité électromagnétique (CEM)

32 Compatibilité électromagnétique (CEM)

Les prescriptions qui suivent sont applicables aux machines électriques tournantes de tension assignée ne dépassant pas 1 000 V (courant alternatif) ou 1 500 V (courant continu) et sont destinées à fonctionner selon les conditions spécifiées ci-dessous.

Les composants électroniques qui sont montés à l'intérieur de la machine électrique tournante et qui sont essentiels pour son fonctionnement (par exemple les systèmes d'excitation tournants) font partie de la machine.

Les prescriptions qui sont applicables à un système d'entraînement final et à ses composants, par exemple un équipement électronique de puissance et de commande, des machines couplées, des appareils de contrôle, etc., qu'ils soient montés à l'intérieur ou à l'extérieur de la machine, sont hors du domaine d'application de cette norme.

Les limites de l'article 12 sont établies pour des conditions de fonctionnement en régime établi. Les régimes transitoires (tels que le démarrage) ne sont pas couverts par le présent article.

32.1 *Limites d'immunité*

Les limites d'immunité des machines à courant alternatif et des machines à courant continu aux variations et aux harmoniques de tension du système connecté, et les limites d'immunité des machines à courant alternatif polyphasées aux déséquilibres du système connecté sont données à l'article 12.

32.2 *Limites d'émission*

NOTE – Les limites dans les tableaux qui suivent sont tirées du CISPR 11 ou du CISPR 12.

19.1 *Polyphase induction motors and d.c. motors (excluding motors in 19.2)*

Replace the first paragraph of this subclause by the following:

The motors shall, whatever their duty and construction, be capable of withstanding for 15 s, without stalling or abrupt change in speed (under gradual increase of torque), an excess torque of at least 60 % of their rated torque, the voltage and frequency (induction motors) being maintained at their rated value.

NOTE – Higher torques are required for some motors manufactured according to IEC 60034-12.

For d.c. motors, the torque shall be expressed in terms of overload current; see 18.3.

Page 115

Add the following two new sections:

Section 14: Electromagnetic compatibility (EMC)

32 Electromagnetic compatibility (EMC)

The following requirements apply to rotating electrical machines with a rated voltage not exceeding 1 000 V a.c. or 1 500 V d.c., and which are intended for operation within the conditions specified below.

Electronic components mounted inside the rotating electrical machine and essential for its operation (for example rotating excitation devices) are part of the machine.

Requirements which are applicable to the final drive system and its components, for example power and control electronic equipment, coupled machines, monitoring devices etc., whether mounted inside or outside the machine, are outside the scope of this standard.

The limitations of clause 12 are fixed for steady-state operating conditions. Transients (such as starting) are not covered by this clause.

32.1 *Immunity limits*

The immunity limits of both a.c. and d.c. machines to variations and harmonics of the system voltage, and those of polyphase a.c. machines to unbalances of the connected system, are given in clause 12.

32.2 *Emission limits*

NOTE – The limits in the tables that follow are taken from CISPR 11 or CISPR 12.

32.2.1 *Machines à induction*

Quand elles sont reliées à un système conformément à l'article 12, les machines à induction ne produisent pas de rayonnements perturbateurs supérieurs aux limites

– du tableau 11 pour les machines avec rotors à cage ou avec rotors bobinés munies d'un dispositif de levage des balais et de court-circuit des bagues; ou

– du tableau 12 pour les machines fonctionnant en permanence avec bagues et balais en contact.

Les émissions de conduction sont intrinsèquement bien inférieures aux limites données au tableau 11.

32.2.2 *Machines synchrones*

Quand elles sont reliées à un système conformément à l'article 12, les machines synchrones ne produisent pas de rayonnements perturbateurs supérieurs aux limites du tableau 11, pour les machines sans bagues ni balais, ou aux limites du tableau 12, pour les machines avec bagues et balais.

L'émission de conduction à basse fréquence est couverte par la section 11. Les émissions de conduction à fréquences supérieures sont intrinsèquement bien inférieures aux limites données au tableau 11.

Tableau 11 – Limites des perturbations électromagnétiques pour les machines fonctionnant sans balais

	Plages de fréquences	Limites
Rayonnement perturbateur	30 MHz à 230 MHz	30 dB(µV/m) quasi crête, mesuré à 10 m de distance[1)]
	230 MHz à 1 000 MHz	37 dB(µV/m) quasi crête, mesuré à 10 m de distance[1)]
Conduction perturbatrice aux bornes d'alimentation à courant alternatif	0,15 MHz à 0,5 MHz Les limites diminuent proportionnellement avec le logarithme de la fréquence.	66 à 56 dB(µV) quasi crête 56 à 46 dB(µV) moyenne
	0,5 MHz à 5 MHz	56 dB(µV) quasi crête 46 dB(µV) moyenne
	5 MHz à 30 MHz	60 dB(µV) quasi crête 50 dB(µV) moyenne

[1)] Peut être mesuré à une distance de 3 m, en augmentant les limites de 10 dB.

32.2.3 *Machines à collecteur*

Les machines à courant continu, fonctionnant avec une tension lissée et les machines à collecteur à courant alternatif, fonctionnant sur un système conformément à l'article 12, ne doivent pas rayonner de perturbations supérieures aux limites du tableau 12.

32.2.1 *Induction machines*

When connected to a system according to clause 12, induction machines do not produce radiated disturbances higher than the limits in

– table 11 for machines with cage rotors or with wound rotors having brush-lifting and short-circuiting devices; or

– table 12 for machines with continuously running slip-rings.

Conducted emissions are inherently much lower than the limits given in table 11.

32.2.2 *Synchronous machines*

When connected to a system according to clause 12, synchronous machines do not radiate disturbances higher than the limits of table 11 for brushless designs, or of table 12 for designs with slip-rings.

The conducted low-frequency emission is covered by section 11. Conducted emissions of higher frequencies are inherently much lower than the limits given in table 11.

Table 11 – Electromagnetic disturbance limits for machines operating without brushes

	Frequency range	Limits
Radiated disturbance	30 MHz to 230 MHz	30 dB(µV/m) quasi peak, measured at 10 m distance[1)]
	230 MHz to 1 000 MHz	37 dB(µV/m) quasi peak, measured at 10 m distance[1)]
Conducted disturbance on a.c. supply terminals	0,15 MHz to 0,5 MHz Limits decrease linearly with logarithm frequency.	66 to 56 dB(µV) quasi peak 56 to 46 dB(µV) average
	0,5 MHz to 5 MHz	56 dB(µV) quasi peak 46 dB(µV) average
	5 MHz to 30 MHz	60 dB(µV) quasi peak 50 dB(µV) average

[1)] May be measured at 3 m distance using the limits increased by 10 dB.

32.2.3 *Commutator machines*

DC machines operating on a smooth voltage and a.c. commutator motors operating on a system according to clause 12 shall not radiate disturbances which are above the limits of table 12.

Les émissions de conduction des machines à collecteur à courant alternatif doivent être inférieures aux limites du tableau 12. Les émissions de conduction des machines à courant continu ne sont pas à considérer car ces machines ne sont pas directement reliées à l'alimentation à courant alternatif.

Tableau 12 – Limites des perturbations électromagnétiques pour les machines fonctionnant avec balais

	Plages de fréquences	Limites
Rayonnement perturbateur	30 MHz à 230 MHz	30 dB(µV/m) quasi crête, mesuré à 30 m de distance[1)]
	230 MHz à 1 000 MHz	37 dB(µV/m) quasi crête, mesuré à 30 m de distance[1)]
Conduction perturbatrice aux bornes d'alimentation à courant alternatif	0,15 MHz à 0,50 MHz	79 dB(µV) quasi crête 66 dB(µV) moyenne
	0,50 MHz à 30 MHz	73 dB(µV) quasi crête 60 dB(µV) moyenne
[1)] Peut être mesuré à une distance de 10 m en augmentant les limites de 10 dB, ou à une distance de 3 m en augmentant les limites de 20 dB.		

32.3 *Essais*

32.3.1 *Essais d'immunité*

Des essais d'immunité ne sont pas exigés pour démontrer la conformité au présent article.

32.3.2 *Essais d'émission*

Pour les machines synchrones de puissance supérieure ou égale à 300 kW (ou kVA), des essais de type d'émission de conduction à basse fréquence doivent être effectués pour vérifier la conformité à 28.1.

Pour les machines à collecteur à courant alternatif, des essais de type en charge doivent être effectués pour l'émission de conduction et l'émission de rayonnement afin de vérifier la conformité à 32.2.3.

Pour les machines à collecteur à courant continu, des essais de type en charge doivent être effectués pour l'émission de rayonnement afin de vérifier la conformité à 32.2.3.

Les essais doivent être conduits suivant le CISPR 11, le CISPR 14, et le CISPR 16, selon le cas.

Aucun autre essai n'est exigé afin de démontrer la conformité au présent article.

Conducted emissions from a.c. commutator machines shall be below the levels of table 12. Conducted emissions from d.c. machines are irrelevant since these machines are not directly connected to the a.c. supply.

Table 12 – Electromagnetic disturbance limits for machines operating with brushes

	Frequency range	Limits
Radiated disturbance	30 MHz to 230 MHz	30 dB(μV/m) quasi peak, measured 30 m distance[1)]
	230 MHz to 1 000 MHz	37 dB(μV/m) quasi peak, measured 30 m distance[1)]
Conducted disturbance on a.c. supply terminals	0,15 MHz to 0,50 MHz	79 dB(μV) quasi peak 66 dB(μV) average
	0,50 MHz to 30 MHz	73 dB(μV) quasi peak 60 dB(μV) average

1) May be measured at 10 m distance using the limits increased by 10 dB, or measured at 3 m distance using the limits increased by 20 dB.

32.3 *Tests*

32.3.1 *Immunity tests*

Immunity tests are not required to demonstrate compliance with this clause.

32.3.2 *Emission tests*

For synchronous machines having outputs of 300 kW (or kVA) or more, type tests for conducted low-frequency emission shall be carried out to verify compliance with 28.1.

For a.c. commutator machines, type tests on load for conducted and radiated emission shall be carried out to verify compliance with 32.2.3.

For d.c. commutator machines, type tests on load for radiated emission shall be carried out to verify compliance with 32.2.3.

The tests shall be carried out in accordance with CISPR 11, CISPR 14, and CISPR 16 as applicable.

No other tests are required to demonstrate compliance with this clause.

Section 15: Sécurité

33 Sécurité

Les machines tournantes conformes à la présente norme doivent satisfaire aux exigences de la CEI 60204-1, sauf spécification contraire dans la présente norme, et dans la mesure du possible, elles doivent également être conçues et construites selon la meilleure forme de conception internationalement acceptée, selon l'application.

NOTE – Il est de la responsabilité du constructeur ou de l'assembleur de l'équipement incorporant des machines électriques de s'assurer que l'équipement complet est sûr.

Cela peut conduire à prendre en considération des normes de produits applicables telles que:

CEI 60079: *Matériel électrique pour atmosphères gazeuses,*
CEI 60335: *Sécurité des appareils électrodomestiques et analogues;*

et d'autres parties de la CEI 60034 y compris:

CEI 60034-5, CEI 60034-6, CEI 60034-7, CEI 60034-8, CEI 60034-9, CEI 60034-11, CEI 60034-12 et CEI 60034-14.

De plus, il peut être nécessaire de considérer la limitation de la température de surface et des caractéristiques similaires; voir par exemple la CEI 60335-1 (1991), article 11: Echauffement.

_____

Section 15: Safety

33 Safety

Rotating machines in accordance with this standard shall comply with the requirements of IEC 60204-1 unless otherwise specified in this standard, and be designed and constructed as far as possible in accordance with internationally accepted best design practice, appropriate to the application.

NOTE – It is the responsibility of the manufacturer or assembler of equipment incorporating electrical machines as components to ensure that the overall equipment is safe.

This may involve consideration of relevant product standards such as:

IEC 60079: *Electrical apparatus for explosive gas atmospheres,*
IEC 60335: *Safety of household and similar electrical appliances;*

and other parts of IEC 60034 including:

IEC 60034-5, IEC 60034-6, IEC 60034-7, IEC 60034-8, IEC 60034-9, IEC 60034-11, IEC 60034-12 and IEC 60034-14.

In addition, it may be necessary to consider limitation of the surface temperature and similar characteristics; see for example IEC 60335-1 (1991), clause 11: Heating.

_____

AVANT-PROPOS

Le présent amendement a été établi par le comité d'études 2 de la CEI: Machines tournantes.

Le texte de cet amendement est issu des documents suivants:

FDIS	Rapport de vote
2/956/FDIS	2/984/RVD

Le rapport de vote indiqué dans le tableau ci-dessus donne toute information sur le vote ayant abouti à l'approbation de cet amendement.

_____

INTRODUCTION

Cet amendement 1 est publié en parallèle avec un amendement équivalent 2 à la CEI 60034-1 (9e édition) de façon que le contenu technique des deux éditions reste le même.

Page 12

1.2 *Références normatives*

Insérer, dans la liste existante, les titres des normes suivantes:

CEI 60204-1: 1992, *Equipement électrique des machines industrielles – Partie 1: Règles générales*

CISPR 11: 1990, *Limites et méthodes de mesure des caractéristiques de perturbations électromagnétiques des appareils industriels, scientifiques et médicaux (ISM) à fréquence radioélectrique*

CISPR 14: 1993, *Limites et méthodes de mesure des perturbations radioélectriques produites par les appareils électrodomestiques ou analogues comportant des moteurs ou des dispositifs thermiques, par les outils et par les appareils électriques analogues*

CISPR 16: *Spécifications des méthodes et des appareils de mesure des perturbations radioélectriques et de l'immunité aux perturbations radioélectriques*

Page 84

8.2.4 *Machines à collecteur*

Remplacer la première phrase de ce paragraphe par la phrase suivante:

Une machine à collecteur doit être capable de supporter, pendant 60 s, 1,5 fois le courant assigné dans la combinaison appropriée des conditions suivantes:

Supprimer le point c).

FOREWORD

This amendment has been prepared by IEC technical committee 2: Rotating machinery.

The text of this amendment is based on the following documents:

FDIS	Report on voting
2/956/FDIS	2/984/RVD

Full information on the voting for the approval of this amendment can be found in the report on voting indicated in the above table.

_____

INTRODUCTION

This amendment 1 is issued in parallel with an equivalent amendment 2 to IEC 60034-1 (ninth edition) in order that the technical content of the two editions remains the same.

Page 13

1.2 *Normative references*

Insert, in the existing list, the titles of the following standards:

IEC 60204-1: 1992, *Electrical equipment of industrial machines – Part 1: General requirements*

CISPR 11: 1990, *Limits and methods of measurement of electromagnetic disturbance characteristics of industrial, scientific and medical (ISM) radio-frequency equipment*

CISPR 14: 1993, *Limits and methods of measurement radio disturbance characteristics of electrical motor–operated and thermal appliances for household and similar purposes, electric tools and electric apparatus*

CISPR 16: *Specification for radio disturbance and immunity measuring apparatus and methods*

Page 85

8.2.4 *Commutator machines*

Replace the first sentence of this subclause by the following:

A commutator machine shall be capable of withstanding, for 60 s, 1,5 times rated current under the appropriate combination of conditions as follows:

Delete item c).

8.3.1 *Moteurs à induction polyphasés et moteurs à courant continu (sauf les moteurs qui font l'objet de 8.3.2)*

Remplacer le premier alinéa de ce paragraphe par l'alinéa suivant:

Les moteurs doivent, quels que soient leur service et leur réalisation, être capables de supporter, pendant 15 s, sans calage ni changement brusque de vitesse (sous une augmentation graduelle de couple), un excès du couple d'au moins 60 % de leurs valeurs assignées, la tension et la fréquence (moteur à induction) étant maintenues à leurs valeurs assignées.

NOTE – Pour certains moteurs fabriqués conformément à la CEI 60034-12, des couples plus importants sont nécessaires.

Pour les moteurs à courant continu, le couple doit être exprimé en termes de surintensité; voir 8.2.4.

Page 106

Ajouter les deux nouvelles sections suivantes:

Section 12: Compatibilité électromagnétique (CEM)

12.1 Compatibilité électromagnétique (CEM)

Les prescriptions qui suivent sont applicables aux machines électriques tournantes de tension assignée ne dépassant pas 1 000 V (courant alternatif) ou 1 500 V (courant continu) et sont destinées à fonctionner selon les conditions spécifiées ci-dessous.

Les composants électroniques qui sont montés à l'intérieur de la machine électrique tournante et qui sont essentiels pour son fonctionnement (par exemple les systèmes d'excitation tournants) font partie de la machine.

Les prescriptions qui sont applicables à un système d'entraînement final et à ses composants, par exemple un équipement électronique de puissance et de commande, des machines couplées, des appareils de contrôle, etc., qu'ils soient montés à l'intérieur ou à l'extérieur de la machine, sont hors du domaine d'application de cette norme.

Les limites de la section 6 sont établies pour des conditions de fonctionnement en régime établi. Les régimes transitoires (tels que le démarrage) ne sont pas couverts par le présent article.

12.1.1 *Limites d'immunité*

Les limites d'immunité des machines à courant alternatif et des machines à courant continu aux variations et aux harmoniques de tension du système connecté, et les limites d'immunité des machines à courant alternatif polyphasées aux déséquilibres du système connecté sont données à la section 6.

12.1.2 *Limites d'émission*

NOTE – Les limites dans les tableaux qui suivent sont tirées du CISPR 11 ou du CISPR 12.

8.3.1 *Polyphase induction motors and d.c. motors (excluding motors in 8.3.2)*

Replace the first paragraph of this subclause by the following:

The motors shall, whatever their duty and construction, be capable of withstanding for 15 s, without stalling or abrupt change in speed (under gradual increase of torque), an excess torque of at least 60 % of their rated torque, the voltage and frequency (induction motors) being maintained at their rated value.

NOTE – Higher torques are required for some motors manufactured according to IEC 60034-12.

For d.c. motors, the torque shall be expressed in terms of overload current; see 8.2.4.

Page 107

Add the following two new sections:

Section 12: Electromagnetic compatibility (EMC)

12.1 Electromagnetic compatibility (EMC)

The following requirements apply to rotating electrical machines with a rated voltage not exceeding 1 000 V a.c. or 1 500 V d.c., and which are intended for operation within the conditions specified below.

Electronic components mounted inside the rotating electrical machine and essential for its operation (for example rotating excitation devices) are part of the machine.

Requirements which are applicable to the final drive system and its components, for example power and control electronic equipment, coupled machines, monitoring devices, etc., whether mounted inside or outside the machine, are outside the scope of this standard.

The limitations of section 6 are fixed for steady-state operating conditions. Transients (such as starting) are not covered by this clause.

12.1.1 *Immunity limits*

The immunity limits of both a.c. and d.c. machines to variations and harmonics of the system voltage, and those of polyphase a.c. machines to unbalances of the connected system, are given in section 6.

12.1.2 *Emission limits*

NOTE – The limits in the tables that follow are taken from CISPR 11 or CISPR 12.

12.1.2.1 *Machines à induction*

Quand elles sont reliées à un système conformément à la section 6, les machines à induction ne produisent pas de rayonnements perturbateurs supérieurs aux limites

– du tableau 19 pour les machines avec rotors à cage ou avec rotors bobinés munies d'un dispositif de levage des balais et de court-circuit des bagues; ou

– du tableau 20 pour les machines fonctionnant en permanence avec bagues et balais en contact.

Les émissions de conduction sont intrinsèquement bien inférieures aux limites données au tableau 19.

12.1.2.2 *Machines synchrones*

Quand elles sont reliées à un système conformément à la section 6, les machines synchrones ne produisent pas de rayonnements perturbateurs supérieurs aux limites du tableau 19, pour les machines sans bagues ni balais, ou aux limites du tableau 20, pour les machines avec bagues et balais.

L'émission de conduction à basse fréquence est couverte par 8.9. Les émissions de conduction à fréquences supérieures sont intrinsèquement bien inférieures aux limites données au tableau 19.

Tableau 19 – Limites des perturbations électromagnétiques pour les machines fonctionnant sans balais

	Plages de fréquences	Limites
Rayonnement perturbateur	30 MHz à 230 MHz	30 dB(µV/m) quasi crête, mesuré à 10 m de distance[1)]
	230 MHz à 1 000 MHz	37 dB(µV/m) quasi crête, mesuré à 10 m de distance[1)]
Conduction perturbatrice aux bornes d'alimentation à courant alternatif	0,15 MHz à 0,5 MHz Les limites diminuent proportionnellement avec le logarithme de la fréquence.	66 à 56 dB(µV) quasi crête 56 à 46 dB(µV) moyenne
	0,5 MHz à 5 MHz	56 dB(µV) quasi crête 46 dB(µV) moyenne
	5 MHz à 30 MHz	60 dB(µV) quasi crête 50 dB(µV) moyenne
[1)] Peut être mesuré à une distance de 3 m, en augmentant les limites de 10 dB.		

12.1.2.3 *Machines à collecteur*

Les machines à courant continu, fonctionnant avec une tension lissée et les machines à collecteur à courant alternatif, fonctionnant sur un système conformément à la section 6, ne doivent pas rayonner de perturbations supérieures aux limites du tableau 20.

12.1.2.1 *Induction machines*

When connected to a system according to section 6, induction machines do not produce radiated disturbances higher than the limits in

– table 19 for machines with cage rotors or with wound rotors having brush-lifting and short-circuiting devices; or

– table 20 for machines with continuously running slip-rings.

Conducted emissions are inherently much lower than the limits given in table 19.

12.1.2.2 *Synchronous machines*

When connected to a system according to section 6, synchronous machines do not radiate disturbances higher than the limits of table 19 for brushless designs or of table 20 for designs with slip-rings.

The conducted low-frequency emission is covered by 8.9. Conducted emissions of higher frequencies are inherently much lower than the limits given in table 19.

Table 19 – Electromagnetic disturbance limits for machines operating without brushes

	Frequency range	Limits
Radiated disturbance	30 MHz to 230 MHz	30 dB(μV/m) quasi peak, measured at 10 m distance[1)]
	230 MHz to 1 000 MHz	37 dB(μV/m) quasi peak, measured at 10 m distance[1)]
Conducted disturbance on a.c. supply terminals	0,15 MHz to 0,5 MHz Limits decrease linearly with logarithm frequency.	66 to 56 dB(μV) quasi peak 56 to 46 dB(μV) average
	0,5 MHz to 5 MHz	56 dB(μV) quasi peak 46 dB(μV) average
	5 MHz to 30 MHz	60 dB(μV) quasi peak 50 dB(μV) average

[1)] May be measured at 3 m distance using the limits increased by 10 dB.

12.1.2.3 *Commutator machines*

DC machines operating on a smooth voltage and a.c. commutator motors operating on a system according to section 6 shall not radiate disturbances which are above the limits of table 20.

Les émissions de conduction des machines à collecteur à courant alternatif doivent être inférieures aux limites du tableau 20. Les émissions de conduction des machines à courant continu ne sont pas à considérer car ces machines ne sont pas directement reliées à l'alimentation à courant alternatif.

Tableau 20 – Limites des perturbations électromagnétiques pour les machines fonctionnant avec balais

	Plages de fréquences	Limites
Rayonnement perturbateur	30 MHz à 230 MHz	30 dB(µV/m) quasi crête, mesuré à 30 m de distance[1)]
	230 MHz à 1 000 MHz	37 dB(µV/m) quasi crête, mesuré à 30 m de distance[1)]
Conduction perturbatrice aux bornes d'alimentation à courant alternatif	0,15 MHz à 0,50 MHz	79 dB(µV) quasi crête 66 dB(µV) moyenne
	0,50 MHz à 30 MHz	73 dB(µV) quasi crête 60 dB(µV) moyenne
[1)] Peut être mesuré à une distance de 10 m en augmentant les limites de 10 dB, ou à une distance de 3 m en augmentant les limites de 20 dB.		

12.1.3 *Essais*

12.1.3.1 *Essais d'immunité*

Des essais d'immunité ne sont pas exigés pour démontrer la conformité au présent article.

12.1.3.2 *Essais d'émission*

Pour les machines synchrones de puissance supérieure ou égale à 300 kW (ou kVA), des essais de type d'émission de conduction à basse fréquence doivent être effectués pour vérifier la conformité à 8.9.2.

Pour les machines à collecteur à courant alternatif, des essais de type en charge doivent être effectués pour l'émission de conduction et l'émission de rayonnement afin de vérifier la conformité à 12.1.2.3.

Pour les machines à collecteur à courant continu, des essais de type en charge doivent être effectués pour l'émission de rayonnement afin de vérifier la conformité à 12.1.2.3.

Les essais doivent être conduits suivant le CISPR 11, le CISPR 14 et le CISPR 16, selon le cas.

Aucun autre essai n'est exigé afin de démontrer la conformité au présent article.

Conducted emissions from a.c. commutator machines shall be below the levels of table 20. Conducted emissions from d.c. machines are irrelevant since these machines are not directly connected to the a.c. supply.

Table 20 – Electromagnetic disturbance limits for machines operating with brushes

	Frequency range	Limits
Radiated disturbance	30 MHz to 230 MHz	30 dB(μV/m) quasi peak, measured 30 m distance[1)]
	230 MHz to 1 000 MHz	37 dB(μV/m) quasi peak, measured 30 m distance[1)]
Conducted disturbance on a.c. supply terminals	0,15 MHz to 0,50 MHz	79 dB(μV) quasi peak 66 dB(μV) average
	0,50 MHz to 30 MHz	73 dB(μV) quasi peak 60 dB(μV) average

[1)] May be measured at 10 m distance using the limits increased by 10 dB or measured at 3 m distance using the limits increased by 20 dB.

12.1.3 *Tests*

12.1.3.1 *Immunity tests*

Immunity tests are not required to demonstrate compliance with this clause.

12.1.3.2 *Emission tests*

For synchronous machines having outputs of 300 kW (or kVA) or more, type tests for conducted low-frequency emission shall be carried out to verify compliance with 8.9.2.

For a.c. commutator machines, type tests on load for conducted and radiated emission shall be carried out to verify compliance with 12.1.2.3.

For d.c. commutator machines, type tests on load for radiated emission shall be carried out to verify compliance with 12.1.2.3.

The tests shall be carried out in accordance with CISPR 11, CISPR 14, and CISPR 16 as applicable.

No other tests are required to demonstrate compliance with this clause.

Section 13: Sécurité

13.1 **Sécurité**

Les machines tournantes conformes à la présente norme doivent satisfaire aux exigences de la CEI 60204-1, sauf spécification contraire dans la présente norme, et dans la mesure du possible, elles doivent également être conçues et construites selon la meilleure forme de conception internationalement acceptée, selon l'application.

NOTE – Il est de la responsabilité du constructeur ou de l'assembleur de l'équipement incorporant des machines électriques de s'assurer que l'équipement complet est sûr.

Cela peut conduire à prendre en considération des normes de produits applicables telles que:

CEI 60079: *Matériel électrique pour atmosphères gazeuses,*
CEI 60335: *Sécurité des appareils électrodomestiques et analogues;*

et d'autres parties de la CEI 60034 y compris:

CEI 60034-5, CEI 60034-6, CEI 60034-7, CEI 60034-8, CEI 60034-9, CEI 60034-11, CEI 60034-12 et CEI 60034-14.

De plus, il peut être nécessaire de considérer la limitation de la température de surface et des caractéristiques similaires; voir par exemple la CEI 600335-1 (1991), article 11: Echauffement.

Section 13: Safety

13.1 **Safety**

Rotating machines in accordance with this standard shall comply with the requirements of IEC 60204-1 unless otherwise specified in this standard, and be designed and constructed as far as possible in accordance with internationally accepted best design practice, appropriate to the application.

NOTE – It is the responsibility of the manufacturer or assembler of equipment incorporating electrical machines as components to ensure that the overall equipment is safe.

This may involve consideration of relevant product standards such as:

IEC 60079: *Electrical apparatus for explosive gas atmospheres,*
IEC 60335: *Safety of household and similar electrical appliances;*

and other parts of IEC 60034 including:

IEC 60034-5, IEC 60034-6, IEC 60034-7, IEC 60034-8, IEC 60034-9, IEC 60034-11, IEC 60034-12 and IEC 60034-14.

In addition, it may be necessary to consider limitation of the surface temperature and similar characteristics; see for example IEC 60335-1 (1991), clause 11: Heating.

AVANT-PROPOS

Le présent amendement a été établi par le comité d'études 2 de la CEI: Machines tournantes.

Le texte de cet amendement est issu des documents suivants:

FDIS	Rapports de vote
2/1031/FDIS 2/1055/FDIS 2/1056/FDIS	2/1058/RVD 2/1070/RVD 2/1071/RVD

Les rapports de vote indiqués dans le tableau ci-dessus donnent toute information sur le vote ayant abouti à l'approbation de cet amendement.

_____

SOMMAIRE

Page 4

Remplacer le titre de l'article 8.1 par le nouveau titre suivant:

8.1 Essais de tension de tenue

Page 12

1.2 Références normatives

Ajouter à la liste existante les titres des normes suivantes:

CEI 60060, *Techniques des essais à haute tension*

CEI 60060-1:1989, *Techniques des essais à haute tension – Partie 1: Définitions et prescriptions générales relatives aux essais*

CEI 61293:1994, *Marquage des matériels électriques avec des caractéristiques assignées relatives à l'alimentation électrique – Prescriptions de sécurité*

Page 14

2.1 valeur assignée

Ajouter la note suivante:

NOTE – La tension assignée ou plage de tensions assignées est la tension assignée ou plage de tensions assignées entre phases aux bornes.

FOREWORD

This amendment has been prepared by IEC technical committee 2: Rotating machinery.

The text of this amendment is based on the following documents:

FDIS	Reports on voting
2/1031/FDIS 2/1055/FDIS 2/1056/FDIS	2/1058/RVD 2/1070/RVD 2/1071/RVD

Full information on the voting for the approval of this amendment can be found in the reports on voting indicated in the above table.

_____

CONTENTS

Page 5

Replace the title of clause 8.1 by the following new title:

8.1 Withstand voltage test

Page 13

1.2 Normative references

Insert in the existing list the title of the following standards:

IEC 60060, *High-voltage test techniques*

IEC 60060-1:1989, *High-voltage test techniques – Part 1: General definitions and test requirements*

IEC 61293:1994, *Marking of electrical equipment with ratings related to electrical supply – Safety requirements*

Page 15

2.1 rated value

Add the following note:

NOTE – The rated voltage or voltage range is the rated voltage or voltage range between lines at the terminals.

Page 18

2.25 équilibre thermique

Ajouter la note suivante:

NOTE – On peut déterminer l'équilibre thermique à partir d'un tracé de l'échauffement en fonction du temps, lorsque les droites entre points pris en début et fin de chacun de deux intervalles de temps raisonnables successifs ont une pente de moins de 2 K par heure.

Page 20

3.2 Services types

Supprimer l'alinéa qui suit ce titre.

Page 26

4.1 Attribution des caractéristiques assignées

Remplacer le deuxième alinéa de cet article par le texte suivant:

Quand des composants auxiliaires (tels que des inductances, des capacités, etc.) sont insérés par le fabricant en tant qu'éléments de la machine, les valeurs assignées doivent se rapporter aux bornes d'alimentation de l'ensemble complet.

Page 28

4.2.3 Caractéristiques assignées pour service périodique

Pas de changement dans le texte français.

Page 30

4.2.6 Caractéristiques assignées pour charge équivalente

Remplacer le texte de ce paragraphe par le texte suivant:

Caractéristiques assignées auxquelles, à des fins d'essais, la machine peut fonctionner à charge constante jusqu'à ce que l'équilibre thermique soit atteint et qui conduisent au même échauffement de l'enroulement statorique qu'à la fin de l'essai en services type.

NOTE – Pour déterminer des caractéristiques assignées du type équivalent, il convient de prendre en compte les charge, vitesse et refroidissement variables du cycle de service.

Le cas échéant, cette classe de caractéristiques assignées est désignée «équ».

Page 19

2.25 thermal equilibrium

Add the following note:

NOTE – Thermal equilibrium may be determined from the time-temperature rise plot when the straight lines between points at the beginning and end of two successive reasonable intervals each have a gradient of less than 2 K per hour.

Page 21

3.2 Duty types

Delete the paragraph under this heading.

Page 27

4.1 Assignment of rating

Replace the second paragraph of this clause with the following new paragraph:

When accessory components (such as reactors, capacitors, etc.) are connected by the manufacturer as part of the machine, the rated values shall refer to the supply terminals of the whole arrangement.

Page 29

4.2.3 Rating for periodic duty

Replace the third paragraph of this subclause with the following new paragraph:

Unless otherwise specified, the duration of a duty cycle shall be 10 min and the cyclic duration factor shall be one of the following values:

15 %, 25 %, 40 %, 60 %.

Page 31

4.2.6 Rating for equivalent loading

Replace the text of this subclause with the following new text:

A rating, for test purposes, at which the machine may be operated at constant load until thermal equilibrium is reached and which results in the same stator winding temperature rise as at the end of the test on the specified duty type.

NOTE – The determination of an equivalent rating should take account of the varying load, speed and cooling of the duty cycle.

This class of rating, if applied, is designated 'equ'.

4.5.2 Alternateurs

Remplacer le deuxième alinéa de ce paragraphe par le texte suivant:

Le facteur de puissance assigné des alternateurs synchrones doit être de 0,8 surexcité, sauf spécification contraire de l'acheteur.

Page 32

4.6 Tension assignée

4.6.1 Généralités

Supprimer ce paragraphe et renuméroter les paragraphes 4.6.2 et 4.6.3 en 4.6.1 et 4.6.2 repectivement.

Page 36

6.1 Alimentation électrique

Supprimer le premier alinéa.

Remplacer le deuxième alinéa et la note de cet article par les textes suivants:

Pour les machines triphasées à courant alternatif, 50 Hz ou 60 Hz, destinées à être directement reliées à un réseau de distribution ou d'utilisation, les tensions assignées doivent être déduites des tensions nominales données dans la CEI 60038.

NOTE – Pour les machines à courant alternatif de forte puissance à haute tension, les tensions peuvent être choisies pour l'obtention de caractéristiques de fonctionnement optimales.

Page 40

6.2.4 Moteurs à courant continu alimentés par convertisseurs statiques de puissance

Supprimer la note de ce paragraphe, en page 42.

Page 44

6.4 Machines triphasées à courant alternatif fonctionnant sur réseaux isolés

Remplacer le texte de cet article par le texte suivant:

Les machines triphasées à courant alternatif doivent être capables de fonctionner en marche continue avec le neutre à un potentiel proche ou égal à celui de la terre. Elles doivent être aussi capables de fonctionner sur des réseaux isolés ayant une phase au potentiel de la terre pendant des périodes de courtes durées très peu fréquentes, par exemple telles que nécessaires pour affranchir normalement le défaut. S'il est prévu de faire fonctionner la machine en permanence, ou pendant de longues périodes, dans ces conditions, il est indispensable de prévoir une machine spéciale avec le niveau d'isolement approprié.

4.5.2 AC generators

Replace the second paragraph of this subclause with the following new paragraph:

The rated power factor for synchronous generators shall be 0,8 lagging (over-excited), unless otherwise specified by the purchaser.

Page 33

4.6 Rated voltage

4.6.1 General

Delete this subclause and renumber subclauses 4.6.2 and 4.6.3 as 4.6.1 and 4.6.2, respectively.

Page 37

6.1 Electrical supply

Delete the first paragraph.

Replace the second paragraph and note with the following new paragraph and note:

For three-phase a.c. machines, 50 Hz or 60 Hz, intended to be directly connected to distribution or utilisation systems, the rated voltages shall be derived from the nominal voltages given in IEC 60038.

NOTE – For large high-voltage a.c. machines, the voltages may be selected for optimum performance.

Page 41

6.2.4 DC motors supplied from static power converters

Delete the note of this subclause on page 43.

Page 45

6.4 Three-phase a.c. machines operating on unearthed systems

Replace the existing clause with the following new clause:

Three-phase a.c. machines shall be suitable for continuous operation with the neutral at or near earth potential. They shall also be suitable for operation on unearthed systems with one line at earth potential for infrequent periods of short duration, for example as required for normal fault clearance. If it is intended to run the machine continuously or for prolonged periods in this condition, a machine with a level of insulation suitable for this condition will be required.

Si les enroulements n'ont pas une isolation identique côté phase et côté neutre, cela doit être spécifié par le constructeur.

NOTE – Il convient que la mise à la terre ou l'interconnexion des points neutres de machines ne soit jamais effectuée sans consultation des constructeurs des machines, à cause des dangers de circulation de courants homopolaires de toutes fréquences dans certaines conditions de fonctionnement et des risques d'incidents mécaniques sur les enroulements lors de défauts entre phase et neutre.

Page 50

7.4 Echauffement d'un élément de machine

Remplacer les deuxième et troisième alinéas de cet article par le texte suivant:

Pour la comparaison avec les limites des échauffements (voir tableau 6 ou 7) ou des températures (voir tableau 11), lorsque cela est possible la température doit être mesurée immédiatement avant qu'on arrête la machine à la fin de l'essai thermique, comme cela est défini à l'article 7.7.

Lorsque cela n'est pas possible, par exemple lors du mesurage direct par la méthode de variation de résistance, voir 7.6.2.3.

7.5.3 Méthode par thermomètre

Remplacer le texte de ce paragraphe par le nouveau texte suivant:

La température est mesurée au moyen de thermomètres appliqués sur les surfaces accessibles de la machine terminée. Le terme «thermomètre» s'applique non seulement aux thermomètres à réservoir, mais aussi aux couples thermoélectriques et thermomètres à résistance externes. Lorsque des thermomètres à réservoir sont utilisés en des points où il existe un champ magnétique intense, variable ou mobile, des thermomètres à alcool doivent être utilisés de préférence aux thermomètres à mercure.

Page 52

7.6.1 Choix de la méthode

Supprimer le point d) du sixième alinéa.

Page 58

7.6.4 Détermination par la méthode du thermomètre

Remplacer le texte de ce paragraphe par le nouveau texte suivant:

Lorsqu'on utilise un couple thermoélectrique ou thermomètre à résistance externe, il ne doit pas être placé à un point inaccessible à un thermomètre à réservoir.

On doit s'efforcer, autant que cela est compatible avec la sécurité, de placer les thermomètres aux points présumés les plus chauds (par exemple dans les développantes à proximité du circuit magnétique) de façon qu'ils soient efficacement protégés du contact avec le fluide de refroidissement primaire et qu'ils soient en bon contact thermique avec l'enroulement ou autre élément de machine.

If the winding does not have the same insulation at the line and neutral ends, this shall be stated by the manufacturer.

NOTE – The earthing or interconnection of the machine's neutral points should not be undertaken without consulting the machine manufacturer because of the danger of zero-sequence components of currents of all frequencies under some operating conditions and the risk of mechanical damage to the windings under line-to-neutral fault conditions.

Page 51

7.4 Temperature rise of a part of a machine

Replace the second and third paragraphs of this clause with the following text:

For comparison with the limits of temperature rise (see table 6 or 7) or of temperature (see table 11), when possible, the temperature shall be measured immediately before the machine is shut down at the end of the thermal test, as described in clause 7.7.

When this is not possible, e.g. when using the direct measurement of resistance method, see 7.6.2.3.

7.5.3 Thermometer method

Replace the existing subclause with the following new subclause:

The temperature is determined by thermometers applied to accessible surfaces of the completed machine. The term 'thermometer' includes not only bulb-thermometers, but also non-embedded thermocouples and resistance thermometers. When bulb-thermometers are used in places where there is a strong varying or moving magnetic field, alcohol thermometers shall be used in preference to mercury thermometers.

Page 53

7.6.1 Choice of method

Delete indent d) from the enumeration in the sixth paragraph.

Page 59

7.6.4 Determination by the thermometer method

Replace the existing subclause with the following new subclause:

When a non-embedded thermocouple or a resistance thermometer is used, it shall not be placed at a point inaccessible to a bulb thermometer.

All reasonable efforts, consistent with safety, shall be made to place thermometers at the point, or points where the highest temperatures are likely to occur (e.g. in the end windings close to the core iron) in such a manner that they are effectively protected against contact with the primary coolant and are in good thermal contact with the winding or other part of the machine.

Quel que soit le thermomètre, la lecture la plus élevée doit être prise comme valeur de la température de l'enroulement ou de l'élément de machine.

7.8 Détermination de la constante de temps thermique équivalente des machines pour service type S9

Supprimer la note de cet article, en page 60.

Page 62

7.10.1 Enroulements à refroidissement indirect

Remplacer le troisième alinéa de ce paragraphe, y compris le texte en retrait, par le nouveau texte suivant:

En cas de lectures par thermomètre effectuées selon 7.6.1, la limite d'échauffement doit être conforme au tableau 6.

Page 64

Tableau 6 – Limites d'échauffement des enroulements à refroidissement indirect par l'air

Remplacer le tableau existant par le nouveau tableau suivant:

The highest reading from any thermometer shall be taken to be the temperature of the winding or other part of the machine.

7.8 Determination of the thermal equivalent time constant for machines of duty type S9

Delete the note of this clause on page 61.

Page 63

7.10.1 Indirect cooled windings

Replace the third paragraph of this subclause, including the enumeration with the following new paragraph:

In the case of thermometer readings made in accordance with 7.6.1, the limit of temperature rise shall be according to table 6.

Page 65

Table 6 – Limits of temperature rise of windings indirectly cooled by air

Replace the existing table with the following new table:

Tableau 6 – Limites d'échauffement des enroulements à refroidissement indirect par l'air

	Classification thermique	**A**			**E**			**B**			**F**			**H**		
	Méthode de mesure Th = Thermomètre, R = Résistance, IIT = Indicateur interne de température	**Th** K	**R** K	**IIT** K	**Th** K	**R** K	**IIT** K	**Th** K	**R** K	**IIT** K	**Th** K	**R** K	**IIT** K	**Th** K	**R** K	**IIT** K
Point	**Partie de la machine**

1c)	AC windings of machines having outputs of 200 kW (or kVA) or less, other than those in items 1d) or 1e)[2)]	–	60	–	–	75	–	–	80	–	–	105	–	–	125	–
1d)	AC windings of machines having rated outputs of less than 600 W (or VA)[2)]	–	65	–	–	75	–	–	85	–	–	110	–	–	130	–
1e)	AC windings which are self-cooled without a fan (IC 40) and/or with encapsulated windings[2)]	–	65	–	–	75	–	–	85	–	–	110	–	–	130	–
2	Windings of armatures having commutators	50	60	–	65	75	–	70	80	–	85	105	–	105	125	–
3	Field windings of a.c. and d.c. machines other than those in item 4	50	60	–	65	75	–	70	80	–	85	105	–	105	125	–
4a)	Field windings of synchronous machines with cylindrical rotors having a d.c. excitation winding embedded in slots, except synchronous induction motors	–	–	–	–	–	–	–	90	–	–	110	–	–	135	–
4b)	Insulated stationary field windings of d.c. machines having more than one layer	50	60	–	65	75	–	70	80	90	85	105	110	105	125	135
4c)	Low-resistance field windings of a.c. and d.c. machines having more than one layer and compensating windings of d.c. machines	60	60	–	75	75	–	80	80	–	100	100	–	125	125	–
4d)	Single-layer windings of a.c. and d.c. machines with exposed bare or varnished metal surfaces.[3)]	65	65	–	80	80	–	90	90	–	110	110	–	135	135	–

[1)] An adjustment for high-voltage a.c. windings may be applicable to these items, (see item 4 of table 8).

[2)] With the application of the superposition test method to windings of machines rated at 200 kW (or kVA) or less with thermal classes A, B, E and F, the limits of temperature rise given for the resistance method may be exceeded by 5 K.

[3)] Also includes multiple layer windings provided that the under layers are each in contact with the circulating primary coolant.

Page 68

Tableau 8

Remplacer les points 1 et 4 du tableau 8 par ce qui suit:

1	Température maximale de l'air ambiant ou de l'air à l'entrée de la machine (θ_c)	0 °C ≤ θ_c ≤ 40 °C	Peuvent être augmentées par accord, mais cette augmentation ne doit dépasser ni la différence de température entre la température du fluide de refroidissement et 40 °C, ni un maximum de 30 K.
		40 °C < θ_c ≤ 60 °C	Réduites de la différence entre la température du fluide de refroidissement et 40 °C
		θ_c < 0 °C ou θ_c > 60 °C	Par accord
4	Tension assignée (U_N)	11 kV < U_N ≤ 17 kV	$\Delta\theta$, pour les indicateurs internes de température (IIT) doivent être réduites de 1 K par tranche (ou fraction de tranche) à partir de 11 kV jusqu'à 17 kV compris
		U_N > 17 kV	$\Delta\theta$, pour les indicateurs internes de température (IIT) doivent être réduites de 6 K et en plus réduites de 1,5 K par tranche (ou fraction de tranche) au-dessus de 17 kV

Page 72

Tableau 10

Remplacer le point 2 du tableau 10, par ce qui suit:

2	Différence d'altitude entre site d'essai (H_T) et site de fonctionnement (H)	1 000 m < H ≤ 4 000 m H_T < 1 000 m	$\Delta\theta_T = \Delta\theta\left(1 - \frac{H - 1\,000\ \text{m}}{10\,000\ \text{m}}\right)$
		H < 1 000 m 1 000 m < H_T ≤ 4 000 m	$\Delta\theta_T = \Delta\theta\left(1 + \frac{H_T - 1\,000\ \text{m}}{10\,000\ \text{m}}\right)$
		1 000 m < H ≤ 4 000 m 1 000 m < H_T ≤ 4 000 m	$\Delta\theta_T = \Delta\theta\left(1 + \frac{H_T - H}{10\,000\ \text{m}}\right)$
		H > 4 000 m ou H_T > 4 000 m	Par accord

Page 69

Table 8

Replace the text of items 1, 2 and 4 with the following new text:

1	Maximum temperature of ambient air or of the air at inlet to the machine (θ_c)	0 °C ≤ θ_c ≤ 40 °C	May be increased by agreement but this increase shall not exceed either the amount by which the coolant temperature is less than 40 °C, or a maximum of 30 K
		40 °C < θ_c ≤ 60 °C	Reduced by the amount by which the coolant temperature exceeds 40 °C
		θ_c < 0 °C or θ_c > 60 °C	By agreement
2	Maximum temperature of the water at inlet to water-cooled heat exchangers (θ_W)	5 °C ≤ θ_w ≤ 25 °C	Increased by 10 K and may be further increased by an amount not exceeding the amount by which the cooling temperature is less than 25 °C
		θ_w > 25 °C	Increased by 10 K and reduced by the amount by which the maximum cooling water temperature exceeds 25 °C

4	Rated stator winding voltage (U_N)	11 kV < U_N ≤ 17 kV	$\Delta\theta$ for embedded temperature detectors (ETD) shall be reduced by 1 K for each 1 kV (or part thereof) from 11 kV up to and including 17 kV
		U_N > 17 kV	$\Delta\theta$ for embedded temperature detectors (ETD) shall be reduced by 6 K plus 1,5 K for each 1 kV (or part thereof) above 17 kV

Page 73

Table 10

Replace the text of item 2 with the following new text:

2	Difference of altitudes of test site (H_T) and operating site (H)	1 000 m < H ≤ 4 000 m H_T < 1 000 m	$\Delta\theta_T = \Delta\theta\left(1 - \frac{H - 1\,000\ \text{m}}{10\,000\ \text{m}}\right)$
		H < 1 000 m 1 000 m < H_T ≤ 4 000 m	$\Delta\theta_T = \Delta\theta\left(1 + \frac{H_T - 1\,000\ \text{m}}{10\,000\ \text{m}}\right)$
		1 000 m < H ≤ 4 000 m 1 000 m < H_T ≤ 4 000 m	$\Delta\theta_T = \Delta\theta\left(1 + \frac{H_T - H}{10\,000\ \text{m}}\right)$
		H > 4 000 m or H_T > 4 000 m	By agreement

Page 76

Tableau 12

Remplacer le point 1 du tableau 12, par ce qui suit:

1	Température du fluide de refroidissement de référence (θ_c)	0 °C ≤ θ_c ≤ 40 °C	Réduites de la différence entre 40 °C et θ_c. Cependant par accord, une réduction inférieure peut être effectuée, sous réserve que si θ_c < 10 °C, la réduction soit au moins égale à la différence entre 10 °C et θ_c
		40 °C < θ_c ≤ 60 °C	Pas de correction
		θ_c < 0 °C ou θ_c > 60 °C	Par accord

Tableau 13

Remplacer le point 2 du tableau 13 par ce qui suit:

2	Différence d'altitude entre site d'essai (H_T) et site de fonctionnement (H)	1 000 m < H ≤ 4 000 m H_T < 1 000 m	$\theta_T = (\theta - \theta_c)\left(1 - \frac{H - 1\,000\ \text{m}}{10\,000\ \text{m}}\right) + \theta_{cT}$
		H < 1 000 m 1 000 m < H_T ≤ 4 000 m	$\theta_T = (\theta - \theta_c)\left(1 + \frac{H_T - 1\,000\ \text{m}}{10\,000\ \text{m}}\right) + \theta_{cT}$
		1 000 m < H ≤ 4 000 m 1 000 m < H_T ≤ 4 000 m	$\theta_T = (\theta - \theta_c)\left(1 + \frac{H_T - H}{10\,000\ \text{m}}\right) + \theta_{cT}$
		H > 4 000 m ou H_T > 4 000 m	Par accord

Page 78

8.1 Essais diélectriques

Remplacer le titre et le premier alinéa de cet article par ce qui suit:

8.1 Essais de tension de tenue

Une tension d'essai telle que définie ci–après doit être appliquée entre les enroulements soumis à l'essai et la carcasse de la machine à laquelle sont reliés le circuit magnétique et les enroulements non soumis à l'essai. L'essai ne doit être effectué que sur une machine neuve et terminée, dont toutes les parties sont en place dans des conditions équivalentes aux conditions normales de fonctionnement; il doit être effectué dans l'atelier du constructeur ou après montage sur site. Si un essai d'échauffement est effectué, l'essai de tension de tenue doit être effectué immédiatement après cet essai.

Remplacer le troisième alinéa de cet article par le nouveau texte suivant:

Sauf exception ci–dessous, la tension d'essai doit être à fréquence industrielle et de forme pratiquement sinusoïdale. La valeur finale de la tension d'essai doit être conforme au tableau 14. Toutefois, pour les machines de tension assignée égale ou supérieure à 6 kV, lorsque la disponibilité d'une installation d'essai à fréquence industrielle n'existe pas et après accord, l'essai peut être effectué en tension continue, à un niveau égal à 1,7 fois la valeur efficace spécifiée au tableau 14.

NOTE – Il est reconnu que, lors d'un essai en tension continue, la distribution de potentiel de surface le long de l'isolation des développantes et les mécanismes de vieillissement sont différents de ceux en tension alternative.

Page 77

Table 12

Replace the text of item 1 with the following new text:

1	Reference coolant temperature (θ_c)	0 °C ≤ θ_c ≤ 40 °C	Reduction by the amount of the difference between 40 °C and θ_c. However, by agreement, a smaller reduction may be applied, provided that for θ_c < 10 °C the reduction is made at least equal to the difference between 10 °C and θ_c.
		40 °C < θ_c ≤ 60 °C	No adjustment
		θ_c < 0 °C or θ_c > 60 °C	By agreement

Table 13

Replace the text of item 2 with the following new text:

2	Difference of altitudes of test site (H_T) and operating site (H)	1 000 m < H ≤ 4 000 m H_T < 1 000 m	$\theta_T = (\theta - \theta_c)\left(1 - \frac{H - 1\,000\ \text{m}}{10\,000\ \text{m}}\right) + \theta_{cT}$
		H < 1 000 m 1 000 m < H_T ≤ 4 000 m	$\theta_T = (\theta - \theta_c)\left(1 + \frac{H_T - 1\,000\ \text{m}}{10\,000\ \text{m}}\right) + \theta_{cT}$
		1 000 m < H ≤ 4 000 m 1 000 m < H_T ≤ 4 000 m	$\theta_T = (\theta - \theta_c)\left(1 + \frac{H_T - H}{10\,000\ \text{m}}\right) + \theta_{cT}$
		H > 4 000 m or H_T > 4 000 m	By agreement

Page 79

8.1 Dielectric tests

Replace the title and the first paragraph of this clause with the following:

8.1 Withstand voltage test

A test voltage, as specified below, shall be applied between the windings under test and the frame of the machine, with the core and the windings not under test connected to the frame. It shall be applied only to a new and completed machine with all its parts in place under conditions equivalent to normal working conditions and shall be carried out at the manufacturer's works or after erection on site. When a thermal test is carried out, the withstand voltage test shall be carried out immediately after that test.

Replace the third paragraph of this clause with the following new paragraph:

Except as stated below, the test voltage shall be of power frequency and as near as possible to a sine wave form. The final value of the voltage shall be in accordance with table 14. However, for machines with a rated voltage 6 kV or greater, when power frequency equipment is not available, then by agreement a d.c. test may be carried out at a voltage 1,7 times the r.m.s. value given in table 14.

NOTE – It is recognized that, during a d.c. test, the surface potential distribution along the end winding insulation and the ageing mechanisms are different from those occurring during an a.c. test.

Remplacer le quatrième alinéa de cet article par le texte suivant:

L'essai doit être commencé avec une tension ne dépassant pas la moitié de la pleine tension d'essai. La tension est ensuite augmentée jusqu'à la pleine tension d'essai, d'une manière progressive ou par degrés ne dépassant pas 5 % de la pleine valeur, la durée de l'augmentation de la tension depuis la moitié jusqu'à la pleine valeur n'étant pas inférieure à 10 s. La pleine tension d'essai est alors maintenue pendant 1 min à la valeur spécifiée dans le tableau 14. Il ne doit pas y avoir de défaut (voir la CEI 60060-1) pendant cette séquence.

Remplacer le septième alinéa de cet article, y compris la note, par le texte suivant:

Pour les moteurs à courant continu alimentés par convertisseurs statiques de puissance, on doit utiliser, pour déterminer la tension d'essai du tableau 14, la tension continue du moteur ou la valeur efficace de la tension alternative assignée entre phases aux bornes d'entrée du convertisseur statique de puissance, selon la valeur la plus élevée.

Remplacer le neuvième alinéa de cet article par le nouveau texte suivant:

Si un utilisateur et un réparateur ont convenu d'effectuer des essais de tension de tenue dans des cas de rebobinage partiel des enroulements ou de révision d'une machine, il est recommandé de procéder comme suit:

Page 80

Tableau 14 – Essais diélectriques

Remplacer le titre du tableau 14 par le nouveau titre suivant:

Tableau 14 – Essais de tension de tenue

Remplacer le point 8 du tableau 14 en page 82, par le nouveau texte suivant:

8	Ensemble de machines et d'appareils électriquement reliés	Il est recommandé d'éviter si possible la répétition des essais des points 1 à 7, mais si l'essai est fait sur un ensemble de machines et d'appareils dont chacun a déjà subi un essai de tension de tenue, la tension d'essai appliquée à un tel ensemble connecté électriquement ne doit pas dépasser 80 % de la tension la plus basse applicable à l'un des éléments individuals de l'ensemble [4)]

Page 86

Ajouter le nouvel article suivant:

8.5 Vitesse de sécurité en fonctionnement des moteurs à induction à cage

Tous les moteurs triphasés à induction à cage à une seule vitesse ayant une désignation de la carcasse inférieure ou égale à 315 et pour des tensions d'alimentation inférieures ou égales à 690 V doivent être capables de fonctionnement continu sûr à des vitesses inférieures ou égales à la vitesse appropriée du tableau 15 sauf indication différente indiquée sur la plaque signalétique.

Replace the fourth paragraph of this clause with the following text:

The test shall be commenced at a voltage not exceeding half of the full test voltage. The voltage shall then be increased to the full value, steadily or in steps of not more than 5 % of the full value, the time allowed for the voltage increase from half to full value being not less than 10 s. The full test voltage shall then be maintained for 1 min in accordance with the value as specified in table 14. There shall be no failure (see IEC 60060-1) during this period.

Replace the seventh paragraph of this clause, including the note, with the following new paragraph:

To determine the test voltage from table 14 for d.c. motors supplied by static power converters, the direct voltage of the motor or the r.m.s. phase-to-phase value of the rated alternating voltage at the input terminals of the static power converter shall be used, whichever is the greater.

Replace the ninth paragraph of this clause with the following new paragraph:

When a user and a repair contractor have agreed to carry out withstand voltage tests in cases where windings have been partially rewound or in the case of an overhauled machine, the following procedure is recommended:

Page 81

Table 14 – Dielectric tests

Replace the title of this table by the following new title:

Table 14 – Withstand voltage tests

Replace the text of item 8 on page 83 with the following new text:

8	Electrically interconnected machines and apparatus	A repetition of the tests in items 1 to 7 above should be avoided if possible, but if a test is performed on a group of machines and apparatus, each having previously passed its withstand voltage test, the test voltage to be applied to such an electrically connected arrangement shall be 80 % of the lowest test voltage appropriate for any individual piece of the arrangement [4)]

Page 87

Add the following new clause:

8.5 Safe operating speed of cage induction motors

All three-phase single-speed cage induction motors of frame number up to and including 315 and for voltages up to and including 690 V shall be capable of safe continuous operation at speeds up to the appropriate speed given in table 15 unless otherwise stated on the rating plate.

Tableau 15 – Vitesse maximale de sécurité en fonctionnement (min^{-1}) des moteurs triphasés à induction à cage, à une seule vitesse, pour des tensions d'alimentation inférieures ou égales à 690 V

Désignation de la carcasse	2 pôles	4 pôles	6 pôles
≤ 100	5 200	3 600	2 400
112	5 200	3 600	2 400
132	4 500	2 700	2 400
160	4 500	2 700	2 400
180	4 500	2 700	2 400
200	4 500	2 300	1 800
225	3 600	2 300	1 800
250	3 600	2 300	1 800
280	3 600	2 300	1 800
315	3 600	2 300	1 800

NOTE – En cas de fonctionnement à des vitesses supérieures à la vitesse assignée, par exemple en cas d'utilisation avec commande de vitesse réglable, les niveaux de bruit et de vibration augmenteront. Il se peut que l'utilisateur ait besoin d'affiner l'équilibrage du rotor du moteur pour un fonctionnement acceptable au-dessus de la vitesse assignée. La durée de vie des paliers peut être réduite. Il convient de porter attention à la périodicité du regraissage ou à la durée de vie de la graisse.

Renuméroter les articles existants 8.5 à 8.9 de 8.6 à 8.10.

Renuméroter les tableaux existants 15 à 18 de 16 à 19.

Page 88

Tableau 15 – Survitesses

Remplacer le point 2c) du tableau 15 par le nouveau texte suivant:
